Complete nucleotide sequence of an influenza virus haemagglutinin gene from cloned DNA

A. G. Porter, C. Barber, N. H. Carey, R. A. Hallewell, G. Threlfall & J. S. Emtage

Searle Research Laboratories, Lane End Road, High Wycombe, Bucks, UK

A synthetic fowl plague virus (FPV) haemagglutinin gene has been cloned in bacteria and the complete sequence of the RNA gene deduced. It is 1,742 nucleotides long and the mRNA codes for 563 amino acids in an uninterrupted sequence. The nature of some of the important domains in the haemagglutinin has been established, and their structure is discussed in relation to their function. Extensive amino acid sequence homologies exist between FPV and human influenza haemagglutinins.

FOWL PLAGUE VIRUS (FPV) like other influenza viruses is a negative-strand virus with a genome of eight separate[1–3] and unique RNA segments[3], two of which code for the surface antigens, haemagglutinin (gene *4*)[4–6] and neuraminidase. The haemagglutinin (HA) is responsible for attaching the virus to cell receptors[7] and for initiating infection[8,9]. It is firmly established that host antibodies are directed against the haemagglutinin[10,11], and that the virus can escape neutralisation by spontaneous mutation, resulting in amino acid changes in the haemagglutinin. These changes may be major and cause pandemics (antigenic shift) or relatively minor and cause epidemics (antigenic drift)[12]. The minor antigenic changes occur more frequently, but their precise nature and location remain unknown.

Due to the difficulty of RNA sequencing with a molecule the size of the HA gene, peptide sequencing was, until recently, the best method of studying antigenic variation of influenza viruses. Ward and Dopheide[13] and Waterfield and Skehel[14] have determined most of the peptide sequence of the mature HA of a Hong Kong strain (H3N2) and an Asian strain (H2N2), respectively. With the introduction of gene cloning and rapid DNA sequencing greater speed is obtained, and certain problems such as the difficulty of sequencing hydrophobic peptides are overcome. In addition, the gene sequence not only predicts the complete amino acid sequence of the mature protein, but will also indicate the sequence of any peptides that are discarded during its maturation and perhaps also if untranslated sequences (introns) interrupt the coding region of the gene.

Gene sequences can also provide information about the structure of genes not evident from the protein sequence, and a means of comparing different virus strains in greater detail than techniques such as hybridisation[15], gel electrophoretic mobility[16] and oligonucleotide mapping[17].

In this article we describe the determination of the complete nucleotide sequence of the FPV haemagglutinin gene using recombinant DNA techniques. The predicted sequence of the HA allows us to correlate some of the known functions with specific structures in the molecule and to compare the amino acid sequence with partial sequences of human influenza haemagglutinins[13,14].

Gene *4* sequences in plasmid pBR322–FPV$_{4-10}$

We chose to polyadenylate the eight virion RNA segments of unfractionated FPV RNA, and reverse transcribe the mixture with an oligo(dT) primer, since the resultant transcripts included substantial numbers of full length or almost full length copies of all eight genes[18].

Table 1 Use of codons in FPV gene *4*

Phe	UUU 13	Ser	UCU 4	Tyr	UAU 7	Cys	UGU 7
	UUC 13		UCC 4		UAC 8		UGC 9
Leu	UUA 6		UCA 13	*Ochre*	UAA 1	*Opal*	UGA 0
	UUG 9		UCG 1	*Amber*	UAG 0	Trp	UGG 8
Leu	CUU 9	Pro	CCU 3	His	CAU 7	Arg	CGU 1
	CUC 4		CCC 1		CAC 4		CGC 0
	CUA 4		CCA 8	Gln	CAA 14		CGA 4
	CUG 8		CCG 4		CAG 11		CGG 3
Ile	AUU 17	Thr	ACU 13	Asn	AAU 23	Ser	AGU 11
	AUC 8		ACC 12		AAC 14		AGC 8
	AUA 15		ACA 15	Lys	AAA 22	Arg	AGA 14
Met	AUG 11		ACG 1		AAG 7		AGG 8
Val	GUU 9	Ala	GCU 12	Asp	GAU 17	Gly	GGU 5
	GUC 6		GCC 3		GAC 9		GGC 10

To clone individual genes, the S_1-nuclease-treated double-stranded FPV cDNA was ligated to *Hin*dIII cut plasmid pBR322 DNA[19] using the *Hin*dIII linker method[20] (see Fig. 1 legend). The mixture was then used to transform[21] *Escherichia coli* K12 HB101. Thirteen tetracycline-sensitive colonies were obtained most of which contained plasmids with small gene inserts as judged by agarose gel electrophoresis. One plasmid, named pBR322–FPV$_{4-10}$, contained a large insert of about 1,700 nucleotides (Fig. 1, lane c) and the plasmid DNA specifically hybridised to a ^{32}P-labelled gene *4* probe[23] (see Fig. 1 legend for details). 59.7% of gene *4* probe was hybridised compared with not more than 3.1% for probes derived from genes *1–3* and *5–8*, demonstrating the presence of gene *4*

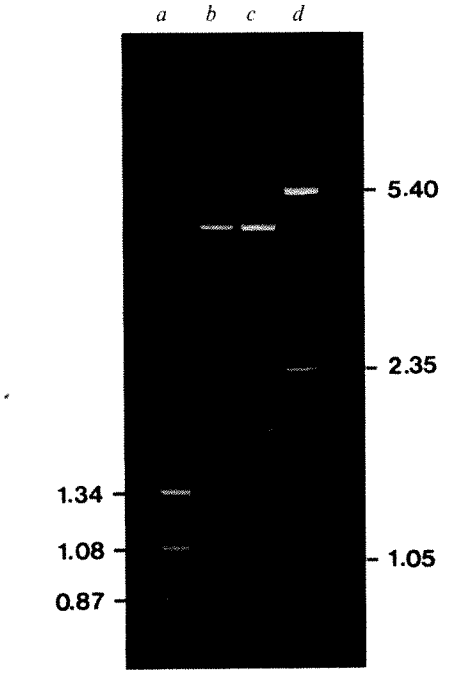

Fig. 1 Characterisation of the FPV gene *4* insert in pBR322 DNA. To prepare double-stranded cDNA from FPV RNA suitable for cloning, the total virion RNA from FPV (Rostock strain) was polyadenylated, and both cDNA strands were synthesised with reverse transcriptase, then treated with S_1 nuclease[18]. Approximately 0.2 μg cDNA was repaired in a 50-μl reaction containing: 50 mM Tris HCl *p*H 7.6, 10mM $MgCl_2$, 50 μM of each deoxynucleoside triphosphate, 1mM β-mercaptoethanol and 1 unit DNA polymerase I (Boehringer), for 10 min at 10°C, then ethanol precipitated. A synthetic *Hin*dIII linker (d[CCAAGCTTGG], Collaborative Research) was kinase-labelled and ligated to the gene mixture in a volume of 10 μl containing: 50 mM Tris HCl *p*H 7.6, 10mM $MgCl_2$, 20 mM dithiothreitol (DTT), 1 mM ATP, approximately 0.2 μg dsDNA, 2 μM 5′-^{32}P-labelled linker and 1 μl T_4 DNA ligase (New England Biolabs) for 7 h at 15 °C. After 7 and 23 h further linker was added to 2 μM, and at 23 h a further 1 μl ligase was added. Excess and unligated linkers were removed by *Hin*dIII digestion (30 units) at 37°C for 90 min, and chromatography through a G-150 column in 50 mM NaCl 0.2% SDS. The excluded peak containing genes was ethanol precipitated and used for ligation to pBR322 DNA as follows: 10 μg pBR322 DNA was digested with *Hin*dIII (25 units) and treated with bacterial alkaline phosphatase. After removing the enzymes with phenol, the linear dephosphorylated plasmid DNA (0.3 μg) was ligated to approximately 80 ng of gene mixture as above, but with 0.5 μl T_4 ligase in 20 μl for 16 h. 10 μl was withdrawn, and used to transform[21] *E. coli* K12 HB101. The culture was plated on L-agar in the presence of 100 μg ml^{-1} ampicillin. Plasmid DNA was purified from tetracycline-sensitive colonies and examined on a 1.4% agarose gel following *Hin*dIII restriction, an example of which is shown. *a*, *Hae*III cut ØX174 DNA markers in kilobase pairs; *b*, pBR322 + *Hin*dIII; *c*, pBR 322–FPV$_{4-10}$ + *Hin*dIII; *d*, *Hin*dIII cut PM2 DNA markers in kilobase pairs. To determine which FPV gene was inserted in each plasmid, ^{32}P-labelled gene probes were prepared and hybridised to plasmid DNA as follows: Plasmid DNA was first prepared by digesting 5 μg plasmid with *Eco*RI (12.5 units) and binding denatured 0.25 μg aliquots to small Millipore disks[23]. 20 μg FPV RNA was electrophoresed in a 3% polyacrylamide gel, *p*H 3.5 in 7M urea, and genes *1–3*, *4*, *5*, *6*, *7* and *8* eluted, incubated for 1 h at 0 °C in 0.1 M NaOH, and labelled with ^{32}P at the newly exposed 5′-ends. Each ^{32}P-labelled probe (approximately 3,000 c.p.m.) was incubated with the DNA-coated Millipore disk at 37°C for 16 h in 100 μl 50% formamide in 3×SSC, 0.1% SDS and 2 μg tRNA. After extensive washing (50% formamide plus 5×SSC, 2×SSC, 2×SSC plus 10 μg ml^{-1} pancreatic RNase and 2×SSC), the disks were dried and counted. Conditions for all restriction enzyme digestions were the same or very similar to those given in the catalogue of New England Biolabs Inc.

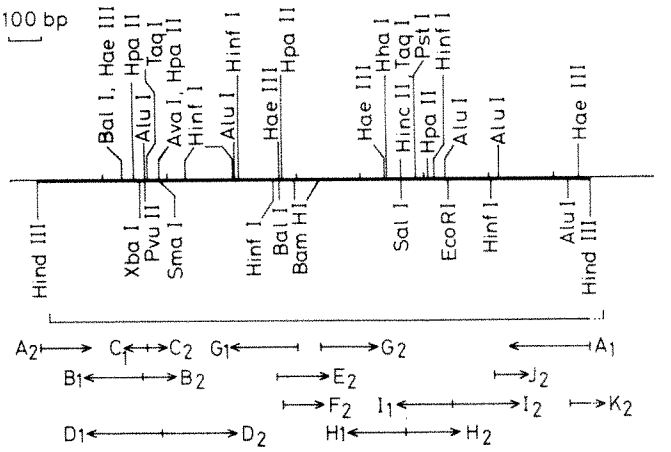

Fig. 2 Restriction enzyme map of the FPV gene *4* insert in pBR322. The insert is the thicker line, beneath which are shown the restriction sites labelled in the sequence analysis. The cloned gene *4* is 46 nucleotides shorter than full length gene *4* at the right hand end which corresponds to the 5′-terminal region of the virionRNA. The relative positions of the 'six base-pair' enzyme sites were first determined by standard mapping procedures. To locate sites for enzymes recognising 4 and 5 base pairs, the gene *4* insert (10 μg) was cut from the plasmid with *Hin*dIII (20 units) for 90 min at 37°C. After removal of enzyme, dephosphorylation and labelling of 5′-ends (Fig. 3), the insert was separated from the plasmid DNA by electrophoresis in a 1.4% agarose gel, and eluted[24]. Subsequent digestion with, for example, *Hin*fI gave at least six fragments as shown by polyacrylamide gel electrophoresis (5% acrylamide, 0.17% bisacrylamide in 50mM Tris-borate *p*H 8.3, 1 mM EDTA). The two *Hin*fI fragments containing the *Hin*dIII ends were identified from their ^{32}P label. The larger of these two was sensitive to *Sma*I, placing it at the left end of the insert. The positions of some of the other *Hin*fI sites were determined from the sensitivity of internal *Hin*fI fragments to *Sal*I and *Eco*RI. The distances sequenced are shown by arrows; those pointing to the left denote sequences derived from the virion RNA strand, and those pointing to the right from the cRNA strand. The vertical line interrupting each arrow indicates the restriction site used for labelling (see Fig. 3 legend for details). The dotted line in distance K_2 refers to the 5′-terminal 46 nucleotides of gene *4* missing from the plasmid. The line above the arrows indicates the position of full length gene *4* relative to the insert.

sequences in pBR322–FPV$_{4-10}$. This plasmid was chosen for sequence analysis as the insert was calculated[18] to be an almost full length copy of gene *4*.

Restriction enzyme mapping and sequence determination

As a first step to sequence analysis of pBR322–FPV$_{4-10}$, the cleavage sites for a number of restriction enzymes were mapped. Remarkably, all the six base-pair enzymes tested (except *Sac*I, *Hin*dIII and *Hpa*I) were found to cut the gene *4* insert at least once (Fig. 2). Some of these enzymes were used in the DNA sequence analysis (see Fig. 3 legend for details).

The lettered arrows in Fig. 2 refer to the distances sequenced and this procedure was usually done twice[22]. In all cases sequences from neighbouring restriction sites were overlapped by at least 15 nucleotides. It was useful to have the sequence on both strands at the overlap, where the bands on the sequencing gels (Fig. 3) were often close together. The few uncertainties were due either to compression[25] of bands at 'hairpin' loops or failure of a chemical reagent to cleave a phosphodiester bond[26] (at methylated C or A). These problems were overcome in all cases by sequencing the complementary DNA strand either in the opposite direction from a neighbouring restriction site, or in the same direction with 3′-end-labelled DNA[27] (see Fig. 4 legend for details).

We have confidence in the number of nucleotides present in the coding region because two protein synthesis reading frames are frequently blocked by nonsense triplets (Fig. 5), leaving one frame open to code for the protein sequence. Striking amino acid sequence homologies between FPV and human HA sequences[13,14] also provide some indication of accuracy in parts of the DNA sequence (Fig. 5).

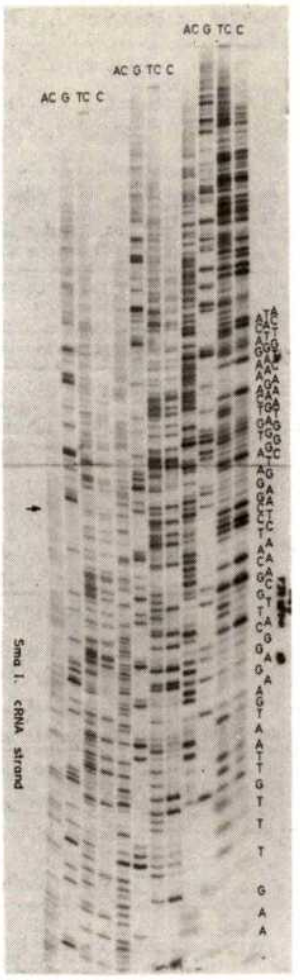

Fig. 3 Sequencing gel of mRNA strand at *Sma*I site. 20 μg pBR322–FPV_{4-10} was digested with *Sma*I (35 units) in 200 μl for 3 h at 37°C, then phenol/chloroform extracted and ethanol precipitated. The 5′-phosphates were removed with 10 μg bacterial alkaline phosphatase in 20 mM Tris *p*H 7.5, 0.1% SDS for 1 h at 37°C. After three phenol/chloroform and two ether extractions, the DNA was again precipitated in ethanol. Labelling was carried out using 200 μCi [γ-^{32}P]ATP (3,000 Ci mMole^{-1}) in a volume of 25 μl containing 3–4 units of T_4-polynucleotide kinase, 5 mM DTT, 0.1 mM spermidine, 50 mM Tris *p*H 9.5 and 10 mM $MgCl_2$. The enzyme was removed as described above for *Sma*I. The labelled DNA was then recut with *Hin*dIII and the two labelled fragments (0.367 and 1.36 kilobases) separated by electrophoresis in a 1.4% agarose gel. Following elution, the two fragments were subjected to the partial chemical degradations[22] and the products resolved in a 30×80×0.04 cm polyacrylamide gel[25] as shown above for the 1.36-kilobase fragment (distance D_2 in Fig. 2). Aliquots of the same sample were loaded at different times so as to read over 200 nucleotides (up to arrow). The other fragments used for sequence analysis were generated as follows: A_1, A_2, *Hin*dIII, label, recut *Eco*RI, isolate 0.447- and 1.28-kilobase fragments. B_1, B_2, *Xba*I, label, recut *Bam*HI, isolate 0.47- and 4.32-kilobase fragments. C_1, C_2, *Pvu*II, label, recut *Hin*dIII, isolate 0.321- and 1.41-kilobase fragments. E_2, J_2, *Hin*fI, label, recut *Sma*I plus *Hin*dIII plus *Pst*I, isolate *Hin*fI→*Pst*I and *Hin*fI→*Hin*dIII fragments (0.452 and 0.320 kilobases). F_2, *Bal*I, label, isolate 1.0-kilobase fragment, recut with *Sal*I, isolate 0.378-kilobase fragment, G_1, G_2, *Bam*HI (also labelled at 3′-ends with α-^{32}P-CTP using deoxynucleotidyl terminal transferase (Fig. 4)), label, recut *Pst*I, isolate 0.306- and 1.566-kilobase fragments. H_1, H_2, *Sal*I, label, recut *Sma*I, isolate 0.758- and 1.232-kilobase fragments, recut 1.232-kilobase fragment with *Bam*HI and isolate 0.96-kilobase fragment. I_1, I_2, *Eco*RI, label, recut *Ava*I, isolate 1.841- and 0.916-kilobase fragments. K_2, *Hae*III, label, isolate 0.608-kilobase fragment (*Hae*III (1,050)→*Hae*III (1,658) in Fig. 5), recut with *Alu*I, isolate 0.042-kilobase fragment (5% polyacrylamide gel as in Fig. 2 legend) [*Alu*I (1,616)→*Hae*III (1,658) in Fig. 5], label and use as a primer with FPV RNA as template (see Fig. 4 legend for details).

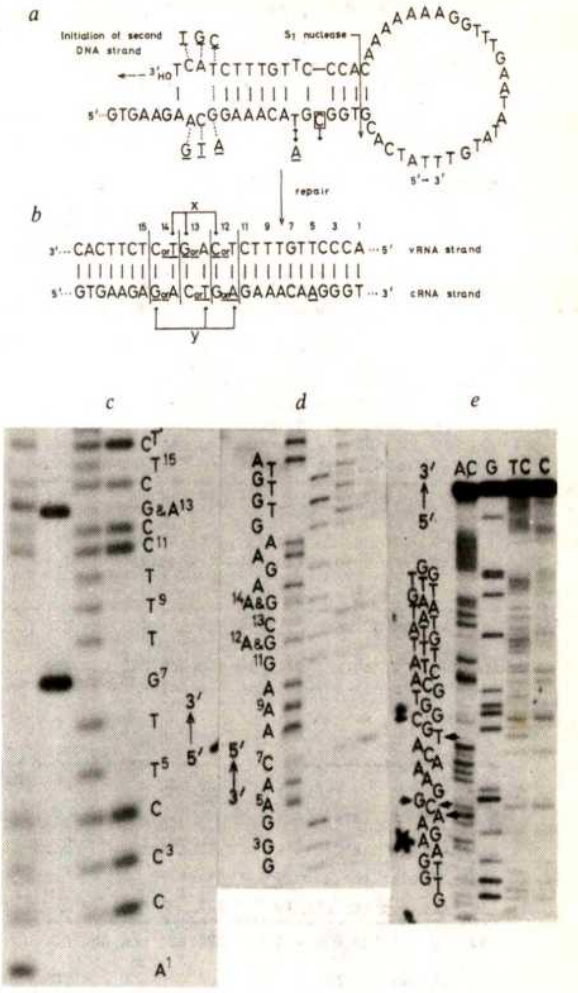

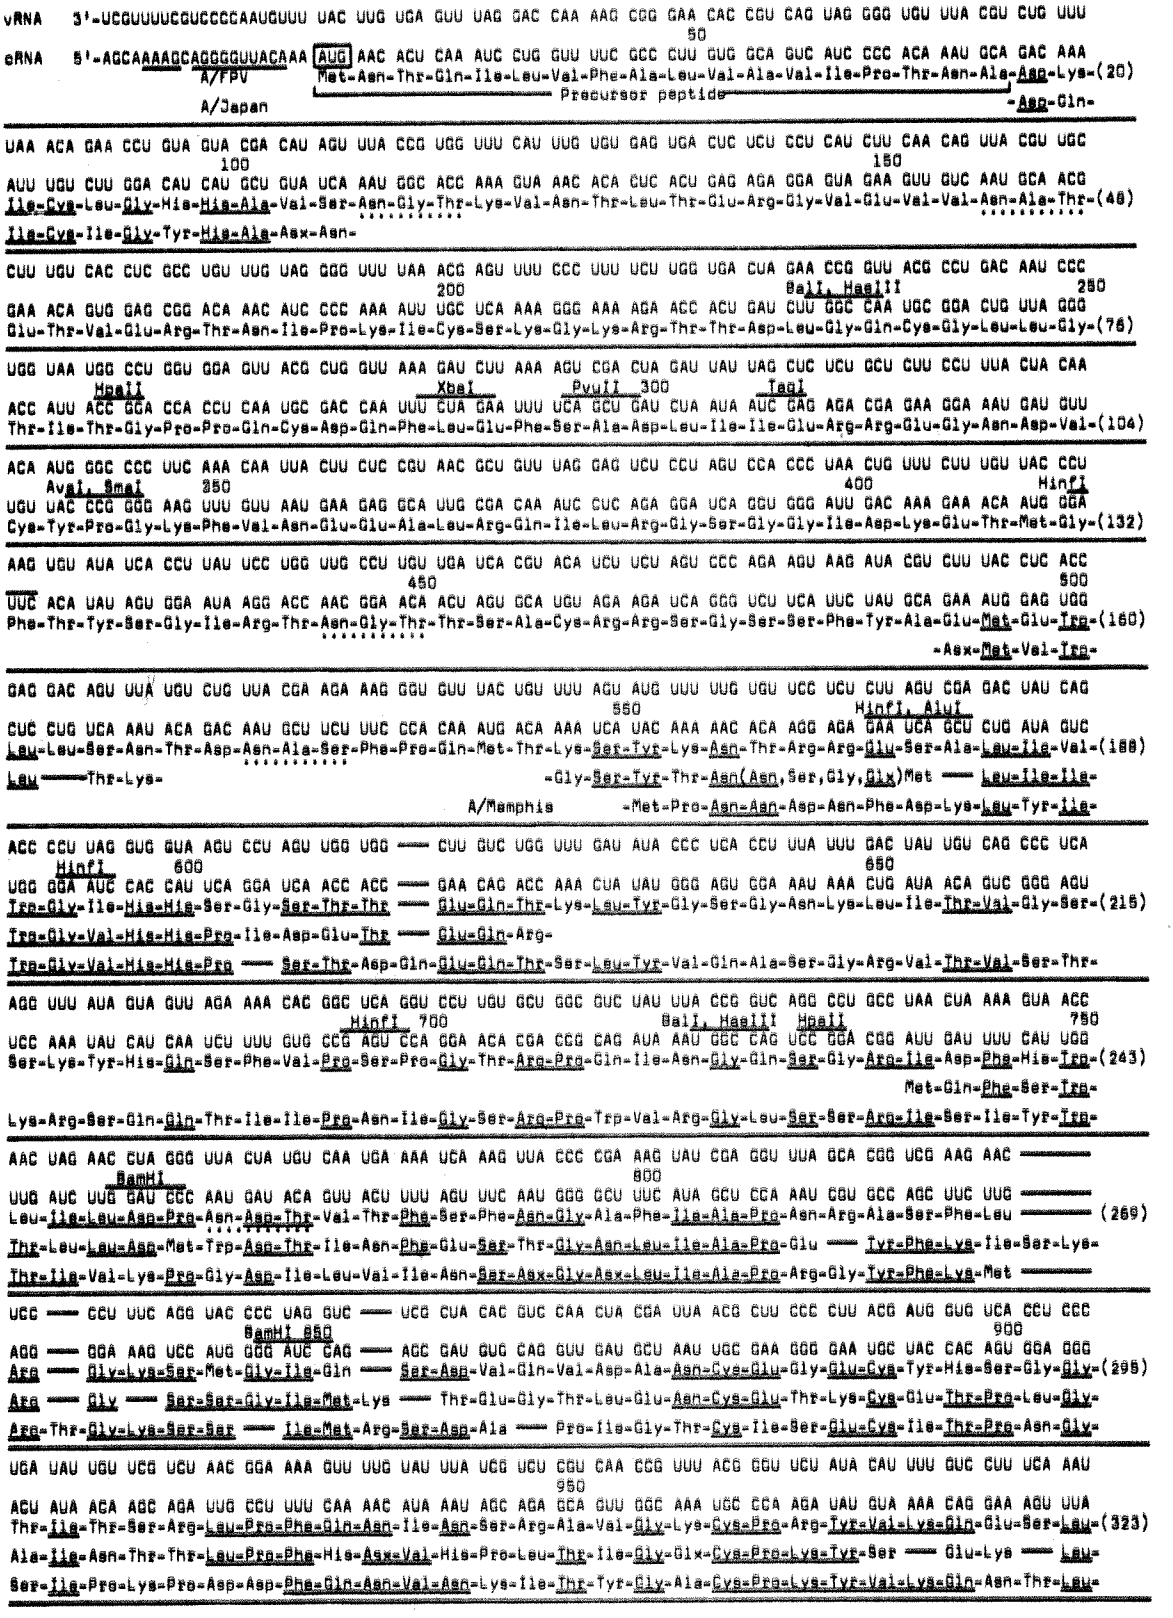

Fig. 4 Origin of the sequence at the right hand end of the gene *4* insert. *a*, The putative hairpin at the 5′-end of the first cDNA strand. *b*, The sequence found at the right hand end of the insert. The dotted lines in *a* refer to nucleotides that arose in the daughter molecules after the first round of plasmid replication. The result in *b* is two plasmids differing in positions 12–14, one with sequence x and the other sequence y. The complementary sequences for the right end of the insert going leftwards are shown in *c* (5′→3′) and *d* (3′→5′). Evidence for heterogeneity is indicated only for the purines. Sequencing in the 3′→5′ direction (*d*) was done by 3′-end labelling of DNA[27]. 20 μg of *Hin*dIII cut plasmid was heated at 90 °C for 5 min and rapidly cooled. The final incubation was: 0.4 mg ml^{-1} DNA, 5 mM Tris, 0.02 mM EDTA, 0.1 M sodium cacodylate *p*H 6.9, 1 mM $CoCl_2$, 0.1 mM DTT, 100 μCi[α-^{32}P]CTP(>350 Ci mMole^{-1}) and 5 units deoxynucleotidyl terminal transferase for 1 h at 37 °C, then for 30 min at 37 °C with an additional 5 units of enzyme. Excess rC was removed with 5 μg pancreatic RNase plus 20 μg tRNA. The enzymes were removed, the DNA was recut with *Eco*RI (50 units) and the 0.447-kilobase fragment was purified by electrophoresis in a 1.4% agarose gel. *e*, The sequence determined from the RNA of gene *4* by priming with a 42-nucleotide restriction fragment derived from the gene *4* insert (see Fig. 3 legend). This sequence spans the right end of the gene *4* insert (*b*), and the five differences with the cloned DNA sequences are arrowed. The 42 base-pair *Alu*I (1,616)→*Hae*III (1,658) fragment was generated from the 5′-^{32}P-labelled *Hae*III (1,050)→*Hae*III (1,658) fragment by *Alu*I digestion (50 units) and purified by 5% polyacrylamide gel electrophoresis. Numbers refer to the distance in nucleotides of the restriction site from the 3′-end of the virionRNA strand (Fig. 5).] The fragment was then labelled at the 5′-ends (Fig. 3) and ethanol precipitated with 15–20 μg FPV RNA. Denaturation was done at 80 °C for 2 min in 80% formamide, 0.01% SDS, 0.01M PIPES *p*H 6.5, 0.4 M NaCl, 1 mM EDTA and the mixture was annealed to the FPV RNA at 50 °C for 20 min. Following ethanol precipitation, cDNA synthesis was carried out with reverse transcriptase[16] and all four unlabelled deoxynucleoside triphosphates. To remove template RNA the cDNA/RNA was ethanol precipitated, briefly exposed to 0.3 M NaOH at 70 °C and neutralised at 20 °C. The large cDNA transcript was purified by 5% gel electrophoresis.

Evidence for repair and heterogeneity in cloned DNA

The first sequences to be established for the gene *4* insert were at the extremities (Fig. 2). The left end of the insert (adjacent to the *Eco*RI site of pBR322 DNA) was found to have the sequence corresponding exactly to the 3'-end of the virionRNA (5'-end of cRNA)[28], but the right hand end could not be matched with the published sequence at the 5'-end of the virionRNA[28]. Therefore an experiment was devised to determine how much of gene *4* was missing. A 42 base-pair restriction fragment from between the *Alu*I and *Hae*III sites nearest the right end of the insert (Fig. 2) was purified, labelled and used as a primer for reverse transcriptase in the presence of FPV RNA and all four unlabelled deoxynucleoside triphosphates[18] (see Fig. 4 legend for details). The strand corresponding to the cRNA presumably annealed to the RNA of gene *4* since the DNA product appeared as a single band in a 5% polyacrylamide gel (not shown). Its length was estimated to be about 140 nucleotides. The band was eluted and the DNA sequenced[22] (Fig. 4*e*). The

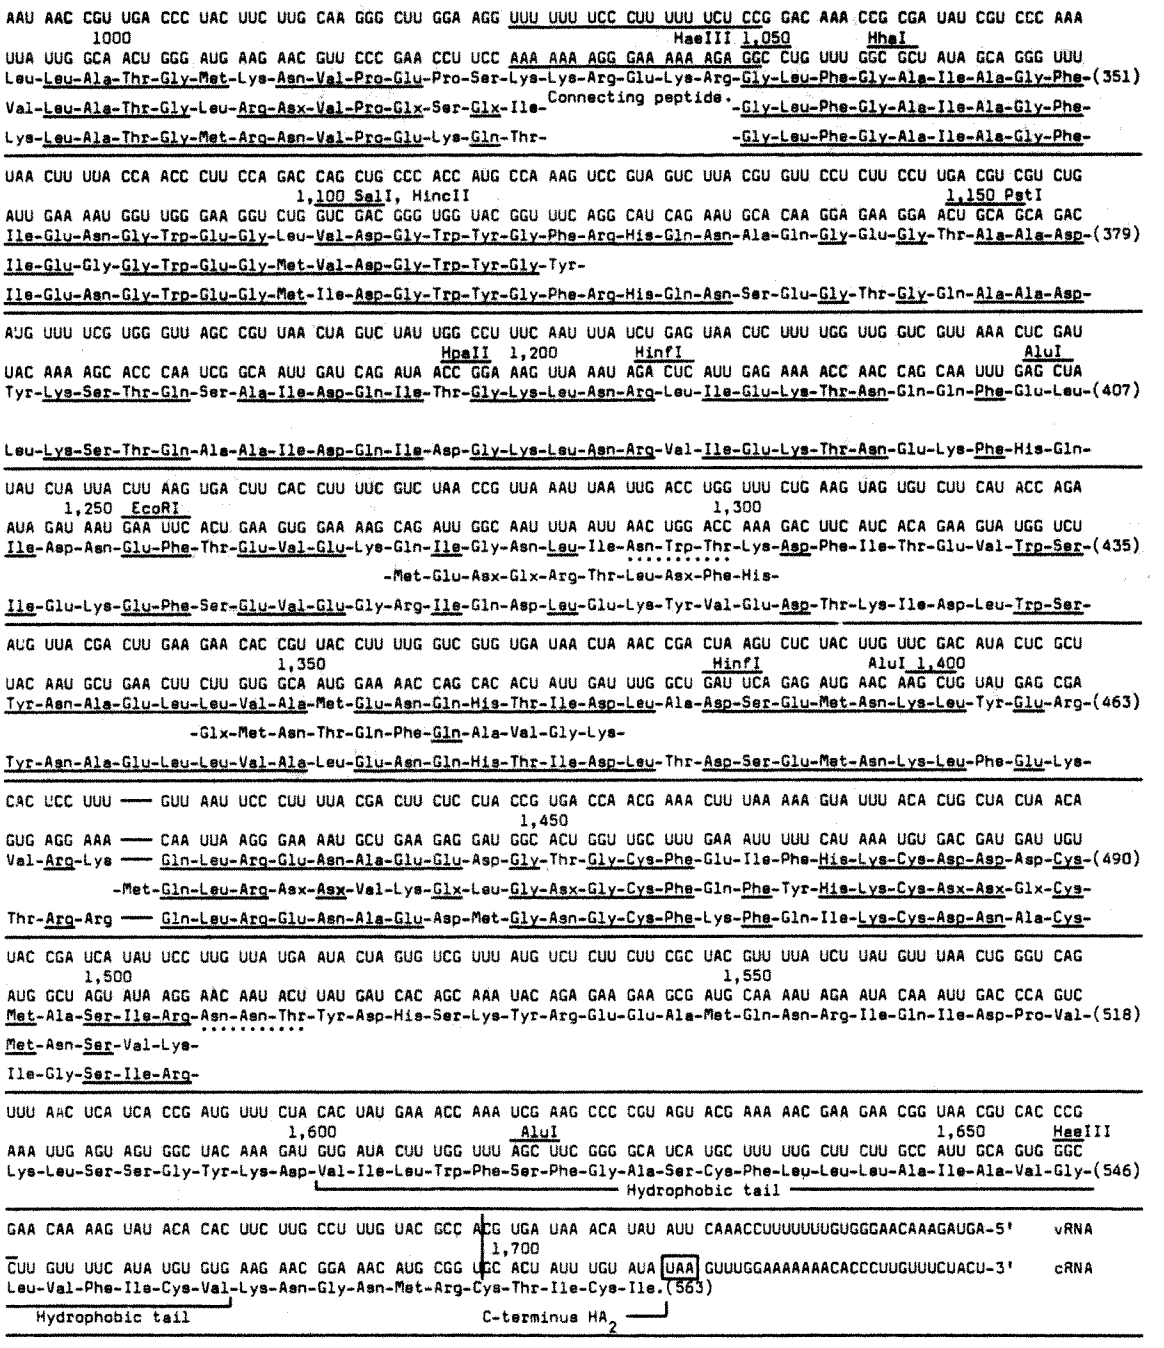

Fig. 5 Nucleotide sequence of the FPV HA gene and comparison of the predicted amino acid sequence of the HA with human HA sequences. The virus RNA (with the 3′-end to the left) is shown above the complementary RNA. Boxes show the initiation codon (AUG) and termination codon (UAA). The positions of the restriction enzyme sites (Fig. 2) found in the corresponding plasmid DNA are indicated by a bar above the cRNA. The heavy underlining near the initiation codon shows two areas of homology with prokaryotic ribosome binding sites. The underlined purine-rich sequence in the cRNA (nucleotides 1,029–1,049) spans the region coding for the peptide connecting HA_1 to HA_2. The vertical line to the left of the termination codon shows the position corresponding to the attachment of the *Hin*dIII linker to the incomplete DNA copy of gene *4*. To the left of this line is shown the actual sequence of the RNA gene (Fig. 4*e*). The predicted amino acid sequence of the immature FPV HA is immediately below the cRNA. The A/Japan/305/57 (H2N2) partial sequence is shown below the complete FPV sequence, and the third line has the A/Memphis/102/72 (H3N2) partial sequence. In maximising homology (underlining) the sequences of these HAs have been aligned according to the positions of the cysteines. Dotted lines below the FPV HA sequence indicate asparagines which may be glycosylated in the mature HA.

23 nucleotides at its 3′-terminal end are complementary to the published sequence of 23 nucleotides at the 5′-end of FPV gene *4*, demonstrating that the strong transcription stop had occurred at the 5′-end of the template RNA[28]. The results show that the FPV gene *4* insert is only 46 nucleotides shorter than the full length gene (Fig. 5). The sequence of 70 nucleotides at the 5′-terminus derived in this way is identical to the sequence determined for the 5′-end of gene *4* by rapid RNA sequencing[53]. However, five differences were found between the sequence deduced by these two independent methods (Fig. 4*e*) and the sequence near the right hand end of the insert determined on both cloned DNA strands (Fig. 4*c*, *d*). These differences (arrowed in Fig. 4*e*) are from top to bottom: absence of a G·C pair in the cloned DNA (Fig. 4*c*, *d*, between positions 3 and 4); an A instead of a T in the cloned DNA (Fig. 4*d*, position 5); and sequence heterogeneity in three positions in the cloned DNA. Both an A and a G are seen at position 13 (Fig. 4*c*) and at positions 12 and 14 (Fig. 4*d*), whereas elsewhere on these sequencing gels cuts are made only at A or G. Heterogeneity in the corresponding pyrimidines is not so obvious since cuts after

C are normally made in both pyrimidine-specific reactions[22].

It is extremely unlikely that these base changes resulted from reverse transcriptase errors, because the conditions of reverse transcription of FPV RNA using the 42-base-pair primer were identical to those used in synthesis of double-stranded DNA for cloning. We suggest instead the following model to explain why the base changes occurred. As with other cDNAs, a hairpin will form and prime the synthesis of the second cDNA strand[29]. The structure in Fig. 4*a* is the only one that can account for the loss of 46 nucleotides from the 5'-end of the gene, provided that the following assumptions are made. First, in the molecule which was cloned the three single-stranded 'bubbles', but not the large terminal loop, survived S_1 nuclease treatment, and second, reverse transcriptase stabilised the interaction of the 3'-terminal T with an A on the opposite strand so that synthesis of the second cDNA strand could commence.

In the proposed hairpin structure (Fig. 4*a*) there are three regions where mismatching occurs, and these regions coincide exactly with the five base changes found in the cloned DNA. The largest 'bubble' (positions 12–14) corresponds to the three positions where sequence heterogeneity is observed (Fig. 4*c*, *d*). The heterogeneity reflects the presence of two plasmids in the bacteria, and it seems probable that these would have arisen after the first round of DNA replication, since it is highly unlikely that one bacterial cell would have been transformed by two plasmid molecules of identical lengths derived from a heterogenous mixture of reverse transcripts[18]. Thus, the mismatched AC pairs at positions 13 and 14 (Fig. 4a) would segregate to a TA pair in one new DNA molecule and a CG pair in the other. Likewise, the GT pair at position 12 becomes a GC in one new DNA molecule and a TA in the other.

In the other two regions excisions could have taken place to restore a perfect duplex (Fig. 4*b*). Thus, the extra C residue nearest the S_1 cleavage site is excised, and two residues to the left (position 5) a T in the strand corresponding to the cRNA is replaced with an A, which can now base-pair with the T on the opposite DNA strand. In contrast to positions 12–14, there is no evidence of sequence heterogeneity, suggesting that the excisions occurred before replication.

The nucleotide sequence of FPV gene *4*

The FPV gene *4* is 1,742 nucleotides long (Fig. 5). This is about 300 nucleotides shorter than a previous estimate[18] of 2,060 nucleotides based on migration rate of RNA in formamide–polyacrylamide gels. The coding region begins with an AUG and is terminated by a single nonsense codon (UAA). Around nucleotides 1,030–1,050 there is an unusual sequence in the mRNA—an uninterrupted stretch of purines most of which code for the peptide connecting the two HA subunits, HA_1 and HA_2 (ref. 13).

During *in vivo* transcription of viral RNA, host mRNAs prime the synthesis of influenza mRNAs adding an extra 10–15 nucleotides to each 5'-end[30] (not shown). At the other end, transcription terminates prematurely[31], probably at the U_7 sequence 17–23 nucleotides from the 5'-end of the virionRNA template. Thus the 5'- and 3'-non-coding regions (including the UAA) are 31–36 and approximately 9 nucleotides long, respectively. The length of the 3' region is therefore short compared with the corresponding region of other mRNAs found in eukaryotic cells[26,29,32]. A putative signal sequence 5'AAUAAA3' has been found in the 3'-non-coding region of many different types of eukaryotic mRNA[26,29,32]. It is absent from FPV gene *4* (Fig. 5) and this resembles the situation in some picornaviruses[33] and one of the mRNAs of vesicular stomatitis virus[34].

The 3'-ends of the cRNA and virionRNA of gene *4* can be aligned so that 12 out of 15 nucleotides are the same. This is significant as a possible signal for the initiation of replication on both these RNAs as has already been noted[28,31]. Homology between 3'-ends also means that the 5'- and 3'-ends of either virionRNA or cRNA are complementary[28], but there is no known function for such an interaction.

A striking feature of the 5'-non-coding region near the AUG (underlined in Fig. 5) is the homology with some prokaryotic ribosome binding sites. These include the R17 replicase[35], T_7 early mRNA[36] and *E. coli* Trp E sites[37]. In FPV gene *4*, there is a characteristic purine-rich sequence, AGGGG, which interacts with the 3'-end of 16S rRNA in prokaryotes[38], followed immediately by UUACA. The latter sequence is present in the prokaryotic sites as UUAC and U-ACA. There is even greater homology between the gene *4* site and a spurious ribosome binding site in Qβ RNA which lacks an AUG[39]. Here at least 12 out of 16 nucleotides are the same. Support for the idea that the gene *4* site is prokaryotic in character comes from experiments on the expression of FPV gene *4* in *E. coli*[40].

Codon usage

The choice between degenerate codons in many mRNAs is frequently non-random, with markedly different preferences in different mRNAs[26,29,32]. In some mRNAs, the most frequently used codons correlate with the abundant species of isoaccepting tRNA[41], while in others the usage reflects the base composition[42]. FPV gene *4* is U-rich (34.3%) and has a low G content (18.5%). Reflecting this, there is a significant bias for codons with A in the third position (notably GAA, AGA and AAA), and against codons with third position C (Table 1).

Gene *4* has an overall deficiency of CG relative to the other 15 dinucleotides. This is not due only to the low G content, since GG sequences are almost twice as abundant. Again reflecting the base composition of the virionRNA, codons with CG in first and second or second and third position rarely occur (Table 1). There is also a deficiency of CG in the eukaryotic genome[43]. In this case it has been suggested that the frequency of CG has been kept to a minimum since cytosine in CG is a major site of DNA methylation and methylated nucleotides are 'hot spots' for mutation[32]. But this cannot be true for influenza, an RNA virus with no known DNA intermediate in its replication.

Amino acid sequence organisation of the FPV haemagglutinin

The immature FPV HA consists of 563 amino acids, of which 18 form the N-terminal 'pre-peptide', 319 are in HA_1, 5 are in a connecting peptide and 221 are in HA_2 (Fig. 5). The amino acid composition shows similarities to human haemagglutinins; for example in the high proline content of HA_1 compared to HA_2, and in the number and distribution of cysteine residues[13,14]. The positions of the cysteines have been highly conserved, perhaps to help give each molecule a basically similar overall shape by disulphide bridging.

Existing evidence suggests that immature HA has a short N-terminal leader sequence which is cleaved off when the process of membrane insertion is complete[14]. The DNA sequence predicts that the FPV leader consists of 18 amino acids, none of which is polar (Fig. 5). From the fifth residue, there is a core of 11 consecutive hydrophobic amino acids. The leader sequence of another influenza A haemagglutinin (RI/5$^-$/57) is 15 residues in length and shows almost no sequence homology with the FPV leader, but like FPV has an uninterrupted sequence of hydrophobic amino acids[44]. The size and non-polar character of these N-terminal peptides is very similar in other secreted proteins[45], which lends strong support to the signal peptide hypothesis[46]. This states that the process of membrane transport is initiated by insertion of a hydrophobic pre-peptide, which is subsequently cleaved off.

Cleavage of HA into HA_1 and HA_2 usually takes place either on smooth internal membranes or at the plasma membrane[47]. This step is essential for infectivity[9] and apparently also for pathogenicity[48]. It is carried out by an unknown host protease with a similar specificity to trypsin[47]. In FPV, the sequence around the cleavage site is Lys-Lys-Arg-Glu-Lys-Arg-Gly (Fig. 5), where the first residue becomes the C-terminus of HA_1 and the last residue the N-terminus of HA_2. The basic nature of these residues accounts for the *in vitro* trypsin cleavage of HA

into HA_1 and HA_2, but it is not known whether only some or all the basic residues are cut either *in vitro* or *in vivo*. In contrast to FPV, the C-terminal amino acid of HA_1 of A/Japan/305/57 is isoleucine[14] and A/Memphis/102/72 has C-terminal threonine[13]. These differences could explain why the susceptibility of HA to cleavage depends on the virus strain[47] as well as on the cell type[48].

In human influenza A strains, the C-terminal part of HA_2 has not yet been sequenced owing to the insolubility of the peptides derived from it, indicating the presence of an extensive hydrophobic region[13,14]. In FPV this begins at residue 527 and extends for 26 amino acids to residue 552 (Fig. 5). Of these, 20 residues are hydrophobic, and are probably involved in anchoring the HA to the viral lipoprotein envelope[14].

There are five potential sites for carbohydrate attachment in HA_1 and two in HA_2 (Fig. 5). This conclusion is based on the presence of the sequences Asn-X-Ser and Asn-X-Thr, which are known to occur in other glycoproteins (including haemagglutinins[13,14]) at sites of N-glycosidic linkage of asparagine to oligosaccharides[14]. Previous studies on the HA from FPV (Dutch) have indicated that there are five or six separate oligosaccharide units, but their exact location was not determined[49]. In A/Japan/305/57, the approximate location of carbohydrate side chains is known to be residues 11, 23, 192 and 303 in mature HA_1 and very near the bromelain cleavage site in HA_2 (ref. 14). In FPV, the sites at residues 30 and 46 in HA_1, and residue 496 in HA_2 seem to correspond to the known A/Japan sites at 11 and 23 in mature HA_1 and the single site in HA_2, respectively.

In Fig. 5, the FPV HA sequence is compared with published partial HA sequences for an H2N2 strain (A/Japan/305/57) and an H3N2 strain[13,14] (A/Memphis/102/72). There is considerable sequence homology (38%) between all strains. This occurs to an even greater extent between FPV and Japan (48%), Memphis and Japan (50%) and FPV and Memphis (55.5%). Conservation of sequence appears to be greater in HA_2 than HA_1, which is not surprising as only HA_1 is thought to undergo antigenic variation.

As pointed out previously, the N-terminal 24 residues of several HA_2 molecules are highly conserved[14], and this now extends to FPV. The cleavage into HA_1 and HA_2 may expose the hydrophobic sequence at the N-terminus of HA_2, which then enables the HA to penetrate the cell membrane[14]. In at least 63% of positions where there is an amino acid difference between any two HAs (Fig. 5), the change can be accounted for by a single nucleotide substitution. This is significantly higher than the value of 38% for all possible pairs of amino acids. This consideration, together with the overlapping nature of the homologies between the three HAs (Fig. 5), implies that the corresponding HA genes have evolved from one and not from two or more distinct ancestors.

Concluding remarks

Gene *4* of FPV is the first influenza virus gene to be completely sequenced and it predicts for the first time the complete amino acid sequence of a viral HA. The gene has some interesting features. The most notable of these are seen in the mRNA—a short 3′ non-coding region, a prokaryotic-like ribosome binding site and an apparent lack of introns.

The sequence analysis of one end of the cloned gene *4* shows clearly that base changes and a base deletion occurred during the cloning process. The model to account for these changes is compelling, implying that because the changes are related to the hairpin at the 5′-end of the first cDNA strand they will not be found elsewhere in the synthetic gene. The results in any event indicate the importance of sequencing RNA independently of cloned DNA.

The HA of influenza viruses is a remarkable multifunctional protein. Our results and those of others have built up a picture of several functionally important domains in the molecule. These are the three hydrophobic regions with distinct functions, the connecting peptide and the carbohydrate attachment sites.

The region of HA that interacts with cell receptors at an early stage in infection remains to be determined, as do the antigenic sites, now known to be in the N-terminal half of HA_1 in a Hong Kong strain[50]. The FPV sequence does, however, provide a framework for determining these sites in combination with other approaches. For example, it will now be possible to determine the primary structure of HA genes from influenza strains that differ only in their reactivity towards monoclonal antibodies[51]. A single nucleotide change would show which amino acid had changed and pinpoint the antigenic site. Ultimately, these methods may enable us to predict which amino acid changes will produce influenza viruses capable of causing epidemics.

We thank Mr G. Catlin and Mr B. Jenkins for technical help, Dr M. Waterfield for useful discussions, Drs G. Air and J. Robertson for allowing us access to their unpublished results, Dr J. Robertson for FPV RNA and Dr A. J. Hale for providing research facilities. All cloning experiments were done in a category III laboratory inspected and approved by GMAG. This report has been published elsewhere[52].

Transposable mating type genes in *Saccharomyces cerevisiae*

James Hicks, Jeffrey N. Strathern & Amar J. S. Klar

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724

A functional copy of the α mating type gene of Saccharomyces cerevisiae *has been cloned by transformation in yeast. Using the Southern blotting procedure it has been shown that three distinct genetic loci implicated in mating type interconversion* (HML, HMR *and* MAT) *contain sequences homologous to the cloned fragment. The restriction fragment associated with each locus exhibits a characteristic size which can be correlated with the mating type allele present at that locus. The characteristic size difference between the* **a** *and α genetic elements made it possible to demonstrate that the homothallic interconversion of mating types in this yeast occurs by DNA rearrangement as proposed in the 'cassette hypothesis'.*

IN the life cycle of homothallic baker's yeast a simple example of cell differentiation occurs in which haploid cells of one mating type (**a** or α) give rise to progeny of the opposite type during mitotic growth. Subsequent conjugation between siblings of opposite cell type establishes the **a**/α diploid phase. Genetic observations on this regulatory switching process have led to the proposal that the mating type genes reside on translocatable DNA elements and that switches between cell types are accomplished by transposition of these elements[1,2]. Although a great deal of genetic evidence has been obtained in support of this 'cassette model' for mating type interconversion, direct demonstration of the proposed transposition mechanism requires identification and cloning of the DNA sequences involved. Using recently developed methods for yeast transformation, we have isolated a copy of the α mating type gene and have used this clone as a hybridisation probe to analyse the arrangement of the mating type genes in the yeast genome and to document that genetic rearrangements are involved in the mating type interconversion process. Our analysis is consistent with the prediction of the cassette model that silent copies of the mating type genes reside at the *HML* and *HMR* loci on chromosome III and that replicas of these unexpressed sequences are translocated to the mating type locus when switching occurs.

Background of the cassette hypothesis

The mating behaviour of *Saccharomyces* yeasts is controlled by the mating type locus (*MAT*) which has two alleles (*MAT***a** and *MAT*α). Cells expressing *MAT***a** (mating type **a**) conjugate readily with cells expressing *MAT*α (mating type α) to create *MAT***a**/*MAT*α diploids. In heterothallic (*ho*) strains the mating types are stable and interconvert only rarely (10^{-6}) while in homothallic (*HO*) strains interconversion of mating types occurs as often as every cell division[3]. A haploid *HO* spore of one mating type can divide twice to yield four daughter cells, two exhibiting the parental mating type and two of the opposite cell type. Progeny of opposite mating type then conjugate to establish *MAT***a**/*MAT*α diploid cell lines in which both switching and mating functions are shut off. This switching process is due to heritable but reversible alterations of the *MAT* locus, and the continued presence of the *HO* gene is not required for the maintenance of the altered state of that locus[4–7].

Two other genetic loci, *HM***a** and *HM*α are also required for switching[8–10]. The genetic nomenclature originally associated with these loci has become somewhat confusing in the light of the function provided by these genes, as described below. We will use here a simpler system which was proposed at the International Congress on Yeast Genetics in 1978. Both forms are presented in Table 1. The *HML* locus (formerly *HM***a**) on the left arm of chromosome III as it is conventionally drawn (see Fig. 1), has two naturally-occurring co-dominant alleles: *HML***a** and *HML*α. Similarly, the *HMR* locus on the right arm of the chromosome has two codominant alleles *HMR***a** and *HMR*α. Either *HML***a** or *HMR***a** is required for the activation of the **a** mating type gene at the mating type locus[11]. Similarly, either *HML*α or *HMR*α is required for the activation of the α mating type gene at the mating type locus[12].

As an explanation of the heritable changes observed at the *MAT* locus during switching, Hicks, Strathern and Herskowitz[1] proposed the 'cassette model' for mating type interconversion in which changes of cell type occur through transposition of **a** and α mating type genes to the *MAT* locus from unexpressed storage sites at *HML* and *HMR*. This model provides a molecular explanation of the heritability of the switched *MAT* alleles and accounts for the striking observation that cells carrying a mutant *mat*α^- (sterile) allele can switch to *MAT***a**$^+$ and then 'healed' to *MAT*α^+ (fertile) within three generations in the presence of the *HO* gene. This healing occurs with a variety of *mat*α^- and *mat***a**$^-$ mutations[13–15]. Therefore, cells capable of switching must contain reserve copies of *MAT***a** and *MAT*α information in the genome. In the cassette model, the *HML* and *HMR* loci are proposed to contain normally unexpressed copies of the mating type gene; the *HML*α and *HMR*α alleles corresponding to α information and the *HML***a** and *HMR***a** alleles to **a** information. A change of cell type is thus viewed as a loss of previously expressed DNA from *MAT* concomitant with an insertion of a replica (cassette) of **a** or α information derived from the *HML* or *HMR* loci. This scheme is shown in Fig. 1. Several predictions of the cassette model have been recently verified: (1) a number of mutations have been characterised which apparently lead to the expression of **a** or α information at the normally silent *HML* and *HMR* loci[15–18]; (2) chromosome rearrangements have been identified which lead to the activation of *HML*α or *HMR***a** by fusion to *MAT*[19]; and (3) mutations in the *HML* and *HMR* loci have been transposed to *MAT* by switching[20,21].

Table 1 Nomenclature of genes involved in switching *MAT**

Old	New
HMa	*HMLα*
hma	*HMLa*
HMα	*HMRa*
hmα	*HMRα*

Capital letters are used for both alleles of each locus to indicate codominance. Recessive mutant alleles are indicated by lower case designations (for example, *hmra*$^-$).

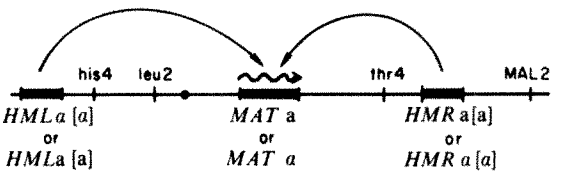

Fig. 1 Map of chromosome III and the cassette model for mating type interconversion. *HML* and *HMR* are sites which contain unexpressed copies of the **a** and α genes. Most laboratory strains exhibit the *HMLα* and *HMR***a** arrangement of storage genes. During interconversion a copy of one of the silent genes is transposed to the *MAT* locus region where it is expressed. The fate of the original *MAT* allele is not clear but it has not been shown to reappear in the genome and is presumably lost.

Identification of a cloned α gene by transformation in yeast

The cassette model makes strong predictions concerning the physical arrangement of the **a** and α DNA sequences in the genome. Clearly, if this model is correct, an α gene at *MAT* should have an homologous counterpart at *HMLα* and *HMRα*. Furthermore, as **a** and α are distinct codominant genes, there must be some physical difference between the *MAT***a** and *MATα* alleles. The cassette model predicts that a similar difference should distinguish the *HML***a** and *HMLα* alleles and the *HMR***a** and *HMRα* alleles. To test these predictions, it was necessary to identify and clone a mating type gene and use it as a hybridisation probe to examine the arrangement of homologous **a** and α sequences in the genome. As there is no easily obtainable physical probe for a yeast mating type gene, we used recently developed techniques for yeast transformation to isolate a mating type α gene by its ability to complement a defective mating type locus in yeast.

The vehicle that we have constructed for cloning yeast genes consists of a 1.4×10^6 molecular weight *Eco*RI fragment of the B form of *Scp*I cloned into the *Eco*RI site of the bacterial vector pBR322 along with a *Pst*I fragment containing the yeast *LEU*2 gene inserted into a *Pst*I site in *Scp*I sequence. This plasmid, designated YEp13 in accord with the nomenclature of Davis *et al.*[22], confers resistance to ampicillin and tetracycline in *Escherichia coli*, complements the bacterial *leu*B6 and yeast *leu*2 mutations, replicates as a plasmid in both organisms and transforms yeast at high frequency[23]. A library of cloned yeast DNA molecules was constructed by ligating *Bam*HI restriction fragments from α haploid strain DC56 into the unique *Bam*HI site in the Tet^R determinant of YEp13 and transforming *E. coli* C600 and screening for Amp^R Leu^+ Tet^S colonies. These colonies containing cloned yeast DNA were divided into subsets of 200 yeast clones each and the clones were amplified by standard procedures as described previously[24].

To detect a plasmid containing the yeast α mating type gene, pooled plasmid DNA was used to transform a yeast strain (DC49) containing a defective *mat***a**$^-$ allele along with a non-reverting double mutation in the *leu*2 gene[25]. The recessive *mat***a**$^-$ allele was used so that transformants containing an α plasmid would exhibit the α mating phenotype (*MATα*/*mat***a**$^- = \alpha$). Transformation was performed as described previously[25] and Leu^+ colonies were screened for α mating phenotype.

One subset of the clone library yielded Leu^+ transformants of DC 56 with the α mating phenotype. Several such isolates were purified as single colonies and DNA was prepared from each by the method of Cryer *et al.*[26]. The isolated DNA was used to re-transform the original bacterial strain (C600) to Amp^R Leu^+, and plasmid DNA was prepared from the bacterial transformants. When the plasmid isolated from this bacterial strain was used to re-transform yeast strain DC49, 100% of the Leu^+ transformants exhibited the α phenotype. This plasmid, designated YEp13-7, was shown by restriction mapping to consist of the original vector plus an insert of four *Bam*HI restriction fragments totalling about 16 kilobase pairs. We demonstrated that only one of those *Bam*HI fragments is required for the α phenotype by subcloning it on YEp13 and transforming DC49. This 6.6-kilobase pair yeast fragment is designated *Bam*26 and is outlined in Fig. 2. The α Leu^+ transformants of DC49 with YEp13-26 (YEp13 plus *Bam*26) were subsequently crossed with a *leu*2$^-$ haploid tester strains. The resultant diploids were able to undergo meiosis and sporulation, indicating that the YEp13-26 plasmid supplies not only the functions necessary for α mating ability but the α sporulation functions as well. A restriction map of the insert in YEp13-26 is presented in Fig. 2. Leu^- mitotic segregants from these strains (the result of loss of the plasmid) concomitantly lost both α mating and sporulation functions.

Physical mapping of the MAT locus

The results described above were consistent with the notion that plasmid YEp13-26 contains a functional α gene but would have also been obtained if the cloned insert somehow disturbed the normal regulatory mechanisms in the transformed cell, allowing an unexpressed copy of α (that is, the copy proposed to be present at *HMLα*) in the DC49 genome to be expressed constitutively. Fortunately, it was possible to identify the cloned DNA as a nucleotide sequence homologous to the mating type locus by mapping the naturally-occurring differences in restriction patterns between **a** and α strains. This restriction fragment polymorphism was observed when the YEp13-26 plasmid was used as a hybridisation probe against Southern blots of restricted DNA from a series of different yeast strains. By crossing strains carrying different versions of a polymorphic restriction fragment and analysing DNA from individual meiotic segregants, the size difference (and hence the cloned DNA sequence used as a probe) can be mapped against known genetic markers. This strategy has previously been used to map a tRNA clone to the *SUP*4 locus of yeast[27] and we have used it to identify a clone containing the yeast *can*1 gene[23].

The α/**a** diploid strain XJ777 used for mapping the cloned α gene was made by crossing the haploid strain DC5 (**a**) and DC55 (α). The complete genotypes of the strains are presented in Table 2. Tetrads were dissected and genetic markers scored by standard techniques[28]. DNA was then isolated from the parent strains and from individual spore clones derived from seven tetrads, digested with restriction endonuclease and displayed on agarose gels for Southern blotting[29]. The blots were probed with ^{32}P-labelled DNA from plasmid pBR322-26.2 which contains the larger *Eco*RI-*Bam*HI subfragment of YEp13-26 (Fig. 2). Figure 3 is an autoradiograph of a blot containing two representative tetrads from XJ777 digested with restriction endonuclease *Hin*dIII. There are two striking features of the hybridisation pattern. First, the hybridisation probe, which contains a *Hin*dIII site and therefore might be expected to hydridise to two chromosomal *Hin*dIII fragments, actually hybridises strongly to four such fragments. Second, two of the

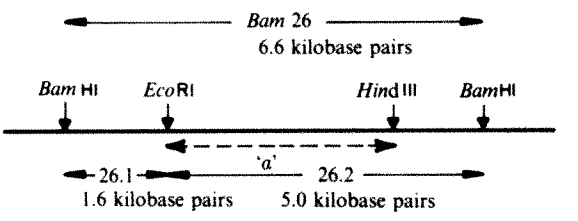

Fig. 2 Restriction map of the *Bam*HI fragment containing α functions. The dotted arrow represents the limits of the α sequence which are homologous with restriction fragments containing *MAT* and *HMR*.

four *Hin*dIII fragments exhibit a length polymorphism which segregates in mendelian fashion. The polymorphic band C exhibits 100% co-segregation with mating type. All seven tetrads had the parental arrangement of mating type relative to the band C polymorphism (complete data not shown). This band shift, linked to the *MAT* locus, which is consistent with a size difference of ~200 base pairs, was also observed when tetrad DNA was cut with *Eco*RI or *Bam*HI. In each case the fragment corresponding to the *MATa* allele seemed to be ~200 base pairs smaller than the *MATα* fragment. Thus, we conclude that the insert in YEp13-26 is homologous to a DNA restriction fragment tightly linked to the *MAT* locus, providing strong additional evidence that this plasmid contains an α structural gene. The segregation of the band A polymorphism is not correlated with mating type and reflects a naturally occurring strain difference at a locus unlinked to *MAT* as described below.

The observation that the *MATα*-containing restriction fragment is ~200 base pairs larger than the fragment containing *MATa* when a variety of restriction enzymes are used indicates that the **a** and α strains used in this mapping differ by a small net insertion at or near the *MAT* locus. We demonstrated that this net size difference reflects a difference in the size of the *MATa* and *MATα* genes by taking a heterothallic yeast strain through a series of changes of cell type: *MATa* to *MATα* to *MATa* to *MATα*. DNA was made from each step and analysed as in Fig. 3. The switches from **a** to α resulted in 200-base pair increases in the *Hin*dIII fragment containing *MAT* and the α to **a** switch resulted in a net 200-base pair decrease (data not shown).

Mapping of *HMR* and *HML* fragments

Two of the additional hybridisation bands in Fig. 3 may be explained in terms of the cassette model; that is, they should represent restriction fragments corresponding to the *HML* and *HMR* loci. We therefore used the same mapping procedure to determine the identity of these bands. As *HML* and *HMR* are normally unexpressed, mapping these loci requires the construction of special strains in which their genotypes can be scored. We have used the *mar*1⁻ allele, first identified by Klar *et al.*[16], to construct mapping strains in which the *HML* and *HMR* alleles are expressed. The *MAR*1 gene product has been proposed to keep the information at the *HML* and *HMR* silent by negative control. In the *mar*1⁻ background, the *HML* and *HMR* loci act as if they contain active mating type genes. A normal haploid strain of genotype *HMLα MATα HMRa* becomes a non-mater in the presence of *mar*1⁻ because both **a** and α mating type genes are expressed. A strain of genotype *mar*1⁻ *HMLα mata⁻ hmra⁻*, on the other hand, behaves as an α-mater because *HMLα* is expressed and the other two loci are defective. In such a strain, the α mating type maps to the *HML* locus, distal to *his*4 (see Fig. 1) rather than to *MAT* (unpublished results). By constructing *mar*1⁻ strains with the appropriate arrangement of mutant and normal mating type alleles, as shown in Table 1, it is possible to place the only functional mating type genes at *HML* (*HMLa*/*HMLα*, strain DC89) or at *HMR* (*HMRa*/*HMRα*, strain DC90). The segregation of the **a** and α phenotypes in these strains thus reflects the segregation of the alleles at *HML* (DC89) or *HMR* (DC90) rather than *MAT*. Segregants from these strains can then be screened by Southern blot analysis as described above. The strategy used in the construction of these mapping strains will be described elsewhere (J.H., J.N.S. and A.J.S.K., in preparation).

In the cassette model *HML* and *HMR* are sources of DNA sequences that become substituted into *MAT*. If, as suggested, *HMRa* is an unexpressed **a** sequence and *HMRα* is unexpressed α, then a strain segregating those alleles (DC90) should exhibit a ~200-base pair polymorphism as demonstrated for *MAT*. Specifically, *HMRα* and *HMLα* should be ~200 base pairs larger than their *HMRa* or *HMLa* alleles. Figure 4 shows autoradiographs of two tetrads derived from diploids in which *HML* or *HMR* has been made heterozygous for active **a** and α regions. The genotypes of these diploids are presented in Table 2. Once again, alleles at these loci are associated with a restriction fragment polymorphism. In Fig. 4*a* the upper band exhibitis the polymorphism co-segregating with the *HMLa* and *HMLα* alleles. As in the case of the *MAT* locus, the **a** (*HMLa*) allele

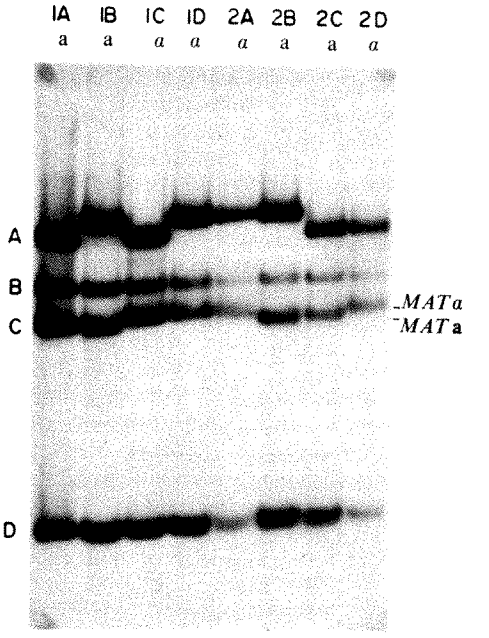

Fig. 3 Autoradiograph of two meiotic tetrads derived from crossing DC5 (**a**) and DC55 (α). DNA was cut with *Hin*dIII, blotted on nitrocellulose and hybridised with pBR322–26.2. The size shift in band C correlates with the segregation of mating type. Yeast culture media and standard yeast techniques have been described previously[3,7]. Yeast strains used in this work are presented in Table 1. Plasmids were propagated in *E. coli* B strain C600 (*leu*B *thr pro*) grown in Luria broth supplemented with ampicillin (100 μg ml^{-1}) or tetracycline (25 μg ml^{-1}) as required or on M9TP (1XM9 salts[30], 1% glucose, 1 mM $MgCl_2$, 20 μg ml^{-1} thiamine, 100 μg ml^{-1} threonine, and 10 μg ml^{-1} proline). *E. coli* strains were grown in M9CAA (1XM9 salts, 1% casaminoacids, 1% glucose, 1 mM $MgCl_2$, and 20 μg ml^{-1} thiamine) for large scale plasmid preparations. Yeast DNA was isolated from appropriate strains by the method of Cryer *et al.*[26] using equilibrium centrifugation in CsCl as a final purification step. Plasmid DNA was isolated from *E. coli* by standard procedures. Restriction endonuclease digestions, DNA ligation reactions and DNA labelling with ^{32}P were performed as described previously[23]. Fractionation of DNA was accomplished by electrophoresis on horizontal agarose slab gels poured and run in 40 mM Tris-acetate, *p*H 7.6, 1 mM EDTA, and 1.0 μg ml^{-1} ethidium bromide. Transfer of DNA from agarose gels to nitrocellulose filters was affected by the method of Southern[29]. Hybridisation of labelled DNA to DNA immobilised on nitrocellulose filters and transformation of yeast cells with purified plasmid DNA was performed as described elsewhere[24,25]. Transformation of bacterial cells with DNA was performed using calcium shocked *E. coli* cells as described elsewhere[31].

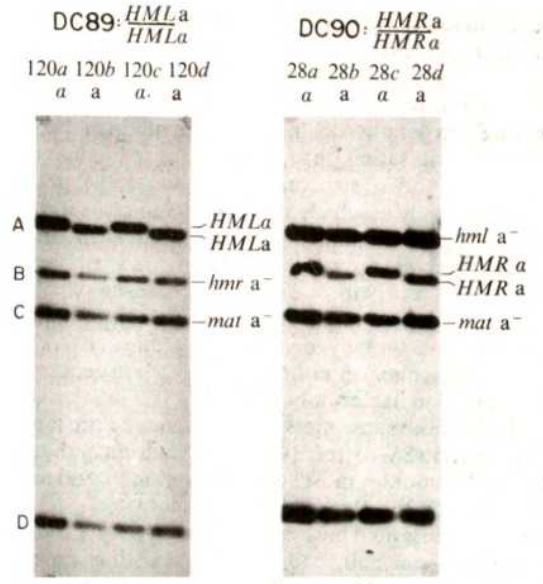

Fig. 4 Autoradiographs of tetrads from diploids DC89 and DC90 showing segregation of size shifts in bands A and B correlated with heterozygosity for *HMLα*/*HML***a** and *HMRα*/*HMR***a**, respectively. DNA was digested with *Hin*dIII and pBR322–26.2 was used as a probe. Approximate sizes of the **a** and α bands in each pair (in kilobase pairs) are: A, 5.8 and 6.0; B, 4.6 and 4.8; C, 4.1 and 4.3.

appears to be ~200 base pairs smaller than the corresponding α (*HMLα*) allele. This size variation segregated in the parental configuration relative to mating type in 12/12 meiotic clones. Similarly, when the *HMR* locus is heterozygous, the size variation can be seen in the second largest band (Fig. 4*b*). Once again, the ~200-base pair larger version co-segregates with the α phenotype, that is, the *HMRα* allele (8/8 meiotic clones tested). The smallest restriction fragment (band D) corresponds to the small partial *Hin*dIII fragment carried on the right-hand end of the *Bam*26 fragment (see Fig. 2) and remains uniform in size.

On the basis of these data, we conclude that the cloned α mating type gene is at least partly homologous with all three loci (*MAT*, *HML*, *HMR*) proposed to contain mating type genes. This homology is observed irrespective of the allele (**a** or α) present at those loci. Furthermore, because a similar size variation is seen at each locus and because such a size difference appears in digests from several different restriction enzymes, we believe that this polymorphism represents an intrinsic size difference between the **a** and α alleles.

Location of the cloned α gene

Because the cloned fragment YEp13-7 hybridises to *MAT*, *HML* and *HMR*, it is not possible from the above observations to determine whether the α gene comes from *MATα* or *HMLα*. Although *HMLα* would not be expected to be expressed in a *MAR*$^+$ strain such as DC49, it is possible that, as an artefact of the cloning procedure, *HMLα* could have been released from the normal mechanism of negative control. In fact, several lines of evidence indicate the α gene identified by function in YEp13-26 is the one originating from *HMLα*: (1) *Bam*H1 fragment 26 (Fig. 2) hybridises more strongly to the restriction fragment identified as *HML* than to *MAT* or *HMR*; (2) the α phenotype of *mar1*$^-$ strains transformed with YEp13-26 is more pronounced than in *MAR*$^+$ strains; and (3) the *Bam*HI-*Eco*RI subclone 26.1 (Fig. 2) does not hybridise to the *Hin*dIII fragments from total yeast DNA identified as containing *MAT* or *HMR* but does hybridise to the *Hin*dIII fragment identified as containing *HML* (data not shown).

Transposition in homothallic switching

From the observations described above, we predicted that the efficient interconversion of mating types observed in homothallic yeast would also involve insertion and excision of DNA at *MAT*. To test this prediction we monitored the effect of a conversion from **a** to α in a homothallic strain. A homothallic (*HO*) haploid normally forms a stable **a**/α diploid cell line through the process of mating type interconversion and mating among the progeny. Once in the **a**/α state, the *HO* switching functions no longer operate and the mating type alleles are stable. However, it is also possible to obtain stable haploid strains containing a functional *HO* gene through manipulation of the states of the *HML* and *HMR* loci. An *HO HMLα MATα HMRα* strain, for example, does not switch and remains an α haploid. The cassette model proposes that such a strain appears stable because it lacks a copy of **a** information. It is therefore possible to construct a strain which has two possible developmental fates. If a cell of genotype *HO HMLα MAT***a** *HMRα* is allowed to divide repeatedly, two cell types are obtained: cells with the original **a** phenotype whose genotype is unchanged, and α cells which now have the *HO HMLα MATα HMRα* genotype. These α cells are no longer capable of switching because they lack a copy of the **a** gene, and, if experimentally isolated from the sibling **a** cells, will grow into a stable α haploid clones. The **a** cells, of course, can still switch, giving rise to addition **a** and α progeny which can mate among themselves to form stable **a**/α diploid cell lines. According to our interpretation of the hybridisation patterns described above, the switching events responsible for the creation of the two distinct cell lines described above should be reflected in the sizes of the restriction fragments carrying mating type genes. The *HO HMLα MATα HMRα* haploid should have only a single *MATα* band, while the diploid *HMLα*/*HMLα MAT***a**/*MATα HMRα*/*HMRα* should contain two *MAT* bands, one derived from the parental **a** allele and one from the newly inserted α allele. Thus we should be able to correlate a change in cell type with a change in the structure of the chromosome in the progeny of a single cell.

The results of such an experiment are shown in Fig. 6. The strains used were created by repeated back crossing (3X) of strains carrying particular arrangements of the *HML* and *HMR* alleles with the normal homothallic diploid X10-1B. X10-1B and JH210 (Fig. 6 lanes *a*, *b*) are stock strains, while lanes *c* and *d* contain DNA from sibling progeny of a single *HO HMLα MAT***a** *HMRα* spore from strain JH204 (Fig. 5). The isolation of these strains followed the strategy described above and used techniques for the pedigree analysis of individual yeast cells described previously[7]. As shown in Fig. 6, the size variation in

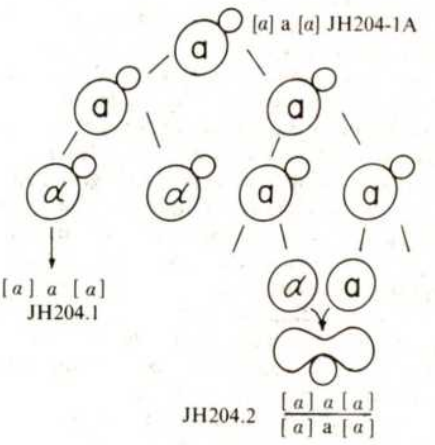

Fig. 5 Schematic of pedigree analysis used to isolate homothallic strains of different developmental potential from a single haploid spore.

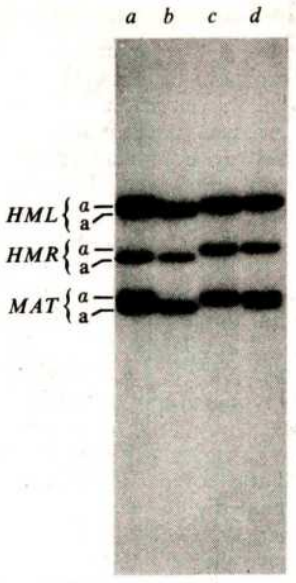

Fig. 6 Autoradiograph of *Hin*dIII digested DNA from related homothallic strains probed with a subfragment of *Bam*26 consisting of the 3.6-kilobase pair *Eco*RI-*Hin*dIII region (see Fig. 1). Lane *a* is the **a**/α diploid X10-1B. Lane *b* is an *HMR***a** haploid strain, JH210. Lanes *c* and *d* represent haploid and diploid derivatives (JH204.1 and JH204.2) of a single haploid spore from JH204.

the *HML*, *HMR* and *MAT* bands follows the genotype of each strain as determined by genetic criteria. Furthermore, the sibling strains (lanes *c* and *d*) which have undergone a homothallic switching event and, thus, a change in developmental potential, show a difference in the banding pattern reflecting the condition of the *MAT* locus. In the haploid α strain (lane *c*) a single *MAT*α band is present, while in the heterozygous diploid (lane *d*) a doublet consisting of one *MAT***a** and one *MAT*α size band appears. It is impossible in such an experiment to trap the original *HO HML*α *MAT***a** *HMR*α cell as a haploid as it continually switches to α and mates. However, we can infer the size of the original *MAT***a** band in that spore from the *MAT***a** bands present in the closely related strains X10-1B and JH210 (lanes *a* and *b*).

Discussion

We have identified and cloned a functional α mating type gene by transformation in yeast. The cloned sequence was identified on the basis of its ability to complement a defect at the *MAT* locus for both mating and sporulation functions. Through subsequent hybridisation analysis we have shown that sequences homologous to the cloned gene exist at three locations in the yeast genome at sites near the *HML*, *HMR* and *MAT* loci. These observations are consistent with the cassette model for mating type interconversion in which the *HML* and *HMR* loci are proposed to contain unexpressed storage copies of the α and **a** mating type genes. The sizes of the three restriction fragments corresponding to these loci depend on the mating type allele present at each locus as defined by genetic criteria. Fragments containing the α allele uniformly appear to be ~200 base pairs larger than corresponding fragments containing **a**. Furthermore, using this apparent size difference, we have shown that both homothallic and heterothallic interconversion of mating types involves a change in size of the restriction fragment mapped to *MAT*. This change in restriction pattern provides a physical demonstration of DNA rearrangement during the interconversion process. We interpret this alteration in restriction pattern as being a consequence of transposition of mating type genes from *HML* and *HMR* to the *MAT* locus.

A fundamental prediction of the cassette model is that the cloned α gene should exhibit strong homology to all copies of α proposed to exist in the genome (*HML*α, *MAT*α, *HMR*α). However, we have observed that this cloned sequence hybridises strongly to genetic loci harbouring **a** mating type alleles as well. This hybridisation may be due to sequence similarity between the **a** and α structural genes or to the presence of recognition sequences which are involved in site specific transposition. We had originally proposed that such recognition sequences might be responsible for the specificity and directionality of the recognition events involved in switching[1,2,32]. However, it is also possible that, although the **a** and α gene products are functionally distinct, they may be coded from closely-related sequences either as overlapping genes similar to those described in bacteriophage ϕX174 (ref. 33) or as processed products of the same message analogous to the large T and small t proteins in SV40 (ref. 34). Determination of the source of the observed homology must await heteroduplex and nucleotide sequence data on the cloned **a** and α genes.

The results presented here confirm the physical predictions of the cassette model and, coupled with existing genetic data, provide strong evidence for transposition of structural genes as a developmental regulatory mechanism. However, the molecular details of the mechanism remain unclear. As the genetic content of the *HML* and *HMR* loci is not altered during switching, it is clear that the transposition event is not reciprocal. Therefore switching must involve both replication of the source gene and substitution of a copy of that gene for the one originally present at *MAT*. It is possible that copies of the source loci are replicated and released as independent molecules which then diffuse to the *MAT* locus and undergo a separate recombination event resulting in substitution. We have looked for a 'diffusible cassette' using Southern blots of undigested DNA from strains constitutive for switching. Such molecules have not been observed in conditions where one molecule per cell would have been easily detectable. Alternatively, replication and substitution need not be separate events but could be the result of a concerted process involving normal recombinatorial intermediates. As we have described elsewhere[32], mating type interconversion is functionally equivalent to unidirectional gene conversion. As substantial homology exists between the source loci and *MAT*, conversion could occur through the same steps proposed for gene conversion at other genetic loci with the proviso that during heteroduplex repair, the source sequences are always maintained. Such unidirectional gene conversion has been observed for certain alleles in both *Sordaria brevicolis*[35] and *Schizosaccharomyces pombe*[36].

The notion that switching might be the result of a modification of normal recombination mechanisms is strengthened by the observation that the *HML*, *HMR* and *MAT* loci are unusually susceptible to intrachromosomal recombination events leading to deletions[37] or chromosomal rearrangements[19]. Genetic selections for rate heterothallic α to **a** interconversions often yield a specific deletion extending from *MAT*α to *HMR***a** (see Fig. 1). This deletion apparently removes the *MAT*α gene and leads to the consitutive expression of *HMR***a**. The converse fusion of *MAT***a** to *HML*α yields a circular chromosome containing the centromere in which *MAT***a** has been removed and *HML*α is expressed[19]. These events may be due to pairing of homologous sequences followed by generalised reciprocal recombination or may represent abortive resolution of intermediates generated during site-specific transposition.

Although our results show that switching from **a** to α involves the net addition of a ~200-base pair segment to the *MAT* restriction fragment, the actual size of the transposed region has not been determined. One possible interpretation of this result is that the expression of the α and **a** mating type genes at *MAT*, *HML* or *HMR* depends solely on the presence or absence, respectively, of a 200-base pair translocatable element. Recent genetic results, however, make this possibility unlikely. Klar and Fogel[21] and Kushner *et al.*[20] have shown that mutant information at the *HML* and *HMR* loci can be transposed to *MAT*

during both homothallic and heterothallic switching. Therefore some sequences present in the a and α structural genes must be transposed during switching. Our results further indicate that the α transposon is less than 3.6 kilobase pairs as described in Fig. 2 legend.

We have demonstrated that interconversion of mating types in *Saccharomyces* involves an alteration of the DNA sequence at the mating type locus of this organism. We believe that this genetic change is the result of sequential transposition of a and α structural genes to *MAT* from the *HML* and *HMR* storage loci. This change is heritable but is also subject to subsequent transposition events. These interconversions of cell type occur in an orderly fashion: (1) they occur in a defined subset of clonally-related cells[3,7]; and (2) cells do not randomly become a or α; they are directed to change to the new cell type by functions under the control of mating type alleles[3,7,14]. Thus, this simple mating type switch exhibits many of the properties observed in the differentiation of cell types in more complex organisms and the mechanism of mating type interconversion provides a paradigm for the study of other developmental events.

We thank Carolyn McGill, Jean McIndoo and Sajida Ismael for technical assistance, James Broach for sharing his technical expertise and suggestions, John Roth for helpful criticism and Marie Moschitta for preparation of the manuscript. This work was supported by NIH grants GM 25678 (A.K.) and GM25624 (J.B.H. and J.N.S.) and NSF grant PCM78-07793 (J.B.H. and J.N.S.). Experiments involving molecular cloning were carried out under the provisions of the NIH guidelines.

A radio jet in SS433

R. E. Spencer

University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire, UK

The peculiar emission line object SS433 (refs 1–3) has variable radio emission and an angular size of <0.1 arc s at centimetric wavelengths[4,5]. The observations reported here show that the object at long radio wavelengths consists of this compact core and also a jet ~1 arc s long aligned in the same position angle as the extended structure in the associated supernova remnant W50. Both components vary in flux density.

The observations were made at 408 MHz with radio-linked interferometers consisting of the MK IA 76 m or the MK II 25 m × 37 m telescopes at Jodrell Bank and the 25 m telescope at Defford. All telescopes were equipped with 1-h circularly polarised feeds. The baseline length was 127 km, giving a resolution limit of 0.2 arc s. The dates of the observations are shown in Table 1. The source was tracked for long periods at all except the first two epochs, enabling models of the radio structure to be fitted to the fringe amplitudes obtained. Short observations only were available on the first two dates, but these were sufficient to allow the flux densities of an unresolved core and an extended component to be found.

A sample visibility curve (that of 10 August 1979) is shown in Fig. 1. Each point represents the average of four integrations of 30 s duration. Also shown is the predicted visibility from a model consisting of an unresolved core (<0.2 arc s diameter) with a flux density of 0.8 Jy plus a gaussian component of 0.9 Jy with dimensions of 1.0 arc s FWHM by <0.2 arc s and elongated in position angle 100°. Similar models were fitted on the other dates giving flux densities, lengths of the elongated component and position angles as shown in Table 1. The flux densities of the two components show significant variations while changes in size and position angle are within measurement errors. The range of resolution available was not sufficient to establish whether the jet is symmetric about the core or displaced by up to ~0.5 arc s in position angle 100°. In addition, lack of phase information gives rise to an ambiguity of 180° in position angle. Nevertheless, the effect of an elongated component is quite clearly seen in the data.

This jet-like feature is very similar to structures found in the central regions of some extragalactic radio sources such as 3C236 (ref. 6) and NGC6251 (ref. 7). It has been proposed that these regions are the sites of radio emission from beams of relativistic matter flowing out from a central nucleus. Such beams may therefore be present in SS433 though at a much lower power level and smaller linear scale. Indeed, beams have

been proposed[8,9] to explain the moving optical emission lines in SS433 and Begelman *et al.*[10] have further suggested that these beams supply energy to the supernova remnant W50. On single-dish maps[11,12] W50 has the appearance of a filled spherical shell of emission ~1° in diameter with regions extending to ~2° in overall size in position angle 100±10°. The orientation of the jet found here (99°) suggests that these outer regions have been blown out by beams from SS433. The range of angular scales involved is ~7,000:1 and the beams must have maintained their orientation within 10° for at least the light travel time from SS433 to the outer regions of W50 which is ~200 yr if SS433 is the suggested distance of 3.5 kpc (ref. 3).

The moving optical emission shows a periodicity in velocity of 164 days and it has been proposed that beams responsible for the emission describe a cone of half-opening angle 17° inclined at 78° to the line of sight[9]. Such motion may be caused by precession of the parent object[10]. The phase of the precession is such that the position angle would be expected to change by 30° from 6 June to 12 August 1979, whereas the measurements show that any precession of the radio jet must be ≲5° over this period. The length of the radio jet if SS433 is at a distance of 3.5 kpc is 5×10^{16} cm, about 100 times the size suggested for the moving regions of optical emission [10] and so it is possible that the effects of precession on position angle are smoothed out within the radio jet.

The flux densities of both the core and jet varied, particularly in the interval between 6 June 1979 and 31 July 1979. The electron lifetime at 1 GHz, if equipartition between relativistic electron energy density and magnetic energy density is assumed in the jet, is ~1,000 yr and so the variability is more likely to arise from adiabatic expansion of small emitting regions in the jet than from radiative energy losses. The core variability may be associated with a changing angle between the beams and the line of sight as recently discussed for much more powerful radio sources[13]. Further study of the flux density variations of the core and jet over several periods and high-resolution VLBI maps will show if this is the case, and give information on relationships between the optical properties and the radio structure.

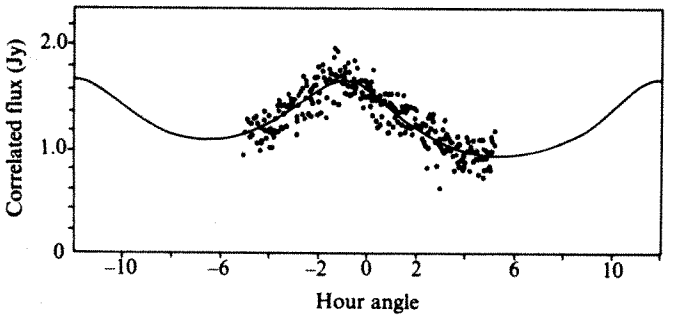

Fig. 1 Fringe amplitude versus interferometer hour angle on 10 August 1979. The smooth curve shows the expected fringe amplitude from a model consisting of a point source coincident with an extended gaussian component 1.0 arc s long to half maximum brightness and <0.2 arc s wide, with flux densities as given in Table 1.

I thank Dr Dennis Walsh for data and Owen Stewart for assistance.

Following the first detection of X-ray emission from the Seyfert galaxy NGC4151[1], later observations[2–4] have demonstrated that the X-ray spectrum up to 100 keV may be described by a power law having a differential spectral index $1<\alpha<1.6$ with a turnover at low energies caused by photoelectric absorption. Recently the results of an observation of this galaxy in the energy range 25–190 keV (ref. 5) have shown it to have a very hard spectrum with $\alpha\cong0.9$. Here more detailed results of the original observation of NGC4151 (ref. 6) using the MISO telescope are presented.

The Seyfert galaxy NGC4151 was studied during the first balloon flight of the MISO telescope[7] on the 22 May 1977. The instrument consisted of a Compton coincidence detector having in this flight an aperture of 3°×20° FWHM which was the same for both the 'single' and 'coincidence' γ-ray events. The telescope (energy range 0.04–20 MeV) was pointed using an alt–azimuth orientation system which had a precision of about 0.3°.

NGC4151 was observed at two different zenith angles (18° and 7°) over a period of ~3 h. Half of this time was devoted to

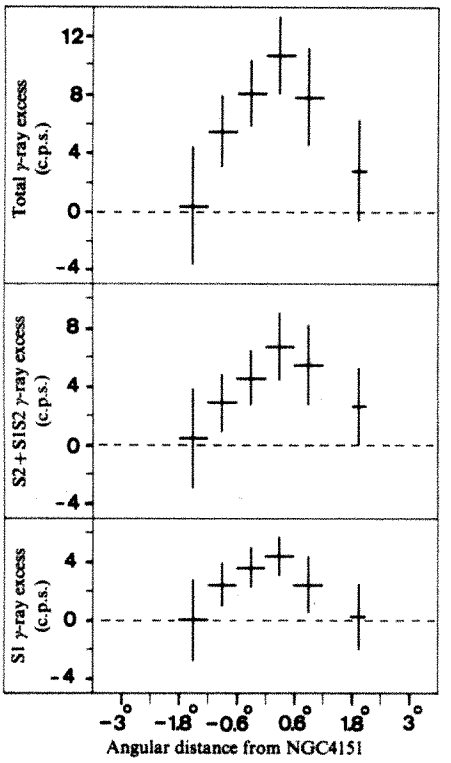

Fig. 1 γ-Ray excesses count rate (S1, S2 + S1.S2, total) versus the angle between the azimuthal axis of the MISO telescope collimator and the direction of NGC4151. The background measurement was made in a region of the sky some way (> 10°) from NGC4151.

background measurements. Observations at each zenith angle were made using an off–on–off source sequence. The source was allowed to transit through the field of view of the telescope and care was taken to ensure that no known X-and γ-ray sources were in the field of view during the background measurements. During the two observations of NGC4151 the float altitude varied between 6.2 and 8.0 mb but stayed close to 7 mb during the ON source observation. The geographical position remained practically constant during the entire observation period. To eliminate any systematic errors due to zenith variations of the background, the data were analysed separately for each zenith angle and the results statistically combined. No dependence of the counting rate on the azimuth angle was found. This means that, if an azimuthal effect exists, it is much less than the statistical errors, as expected from the fact that the entire observation was carried out at small zenith angles. Study of the housekeeping data and in flight γ-ray calibrations showed that there were no measurable changes in the gain of the system during the period. The only measurable systematic change of the background counting rate was due to altitude fluctuations. This variation, measured during the OFF source period, was found to be well described by a linear relationship with pressure for each detector element at both zenith angles. During the ON source period the background counting rate, computed from a knowledge of the balloon altitude, was subtracted from the counting rate generated by the source plus background for each channel. In this way the contribution from the source was obtained, giving a γ-ray excess of 3.0 ± 0.7 counts per second (c.p.s.) for the S1 detector (liquid scintillator), 3.1 ± 0.9 c.p.s. for the S2 detector (sodium iodide) and 1.1 ± 0.4 (c.p.s.) for the S1S2 Compton-coincidence system. The total γ-ray excess was 7.2 ± 1.2 c.p.s., which corresponded to a 6σ excess. This was considerably larger than the upper limit of the sum of all possible systematic errors. The correlation between the excess count rate and the angle between the azimuthal axis of the collimator and the direction of NGC4151 is shown in Fig. 1. The absence of data between 1.2° and 1.8° in Fig. 1 is associated with a loss of recorded data. The lack of data just outside the 3° field of view of the MISO telescope is a consequence of the background measurements being made in a region of the sky some way (> 10°) from NGC4151. A χ^2 best fit of the angular profile data gives the γ-ray excess emission centred about a position $182.2° \pm 0.8°$ in RA, which effectively coincides with the position of the Seyfert galaxy NGC4151 (RA = 182.06°). The positional uncertainty associated with the second (zenith) axis is about ± 10°. The only other known X-ray source which came within the field of view during this observation was the BL Lac object 2A1219+305. However, as this object was at the edge of the aperture of the telescope (10% relative efficiency for photon detection) the proposed identification of the observed γ-ray excess with NGC4151 seems justified.

A technique similar to that used by Dolan[8] was used to convert the energy loss spectrum in each of the three individual γ-ray channels S1, S2, S1S2 to a photon spectrum at the top of atmosphere. The absorption of photons in the residual atmosphere and the redistribution of photon energies through Compton interactions and pair production as well as the energy resolution of the telescope were taken into account. The precision of the system was estimated to be better than 10%. A statistical combination of all three individual spectra is shown in Fig. 2 together with some relevant X-ray measurements. For clarity, the measurements of OSO7 (ref. 2) and the 1976 Ariel 5

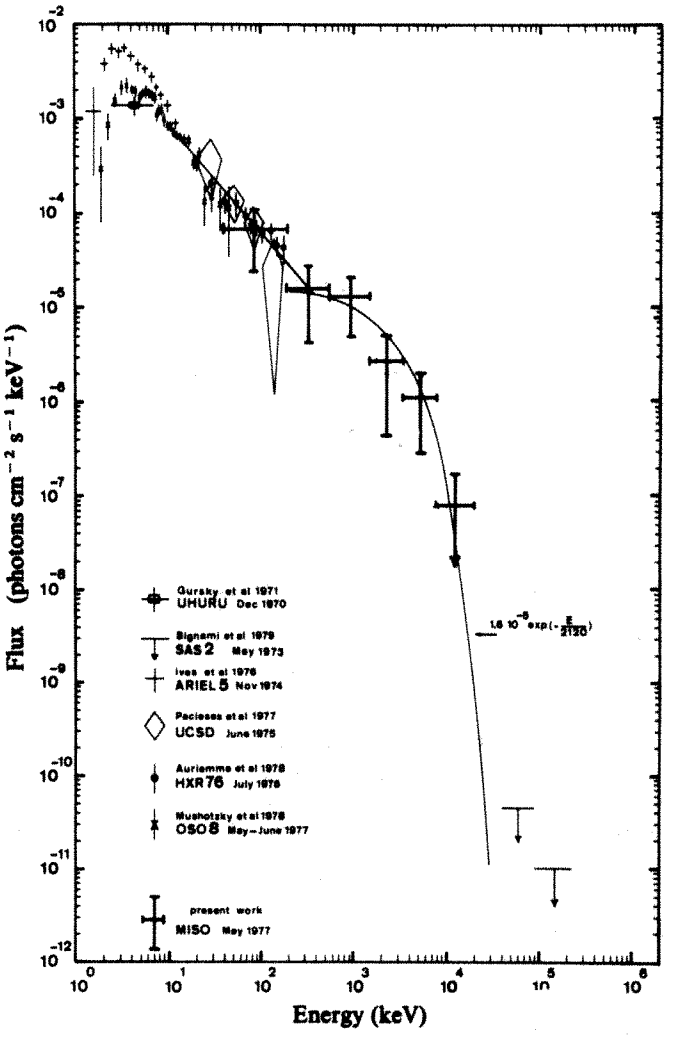

Fig. 2 The photon spectrum of NGC4151 obtained by the MISO telescope is shown together with some previous hard X-ray data. Also shown are the 2σ upper limits obtained by SAS2 at high energy[11].

data[9] have not been shown as they are essentially identical to the more recent measurements of OSO8 (ref. 10). The figure does not show the low energy γ-ray results reported earlier by the Max Planck group[11] because of the uncertainty cast on the validity of this measurement by a more refined analysis of the data[12]. Also shown are the 2σ upper limits set by SAS2 at higher energies[13].

The Ariel 5 (ref. 14) and the OSO8 data provide evidence for the variability of NGC4151 on a time scale of about one week with changes in the flux of about a factor of 2. The observation with the MISO telescope was made on the 23 May 1977, a few days before the OSO8 observations. Inspection of the light curve from OSO8 suggests that the source was in 'high' state of activity during our observation period. The recently reported upper limits at MeV energies by the Rice group[15] and by the University of California[16] indicate that time variability in the γ-ray emission of NGC4151 must exist over a period of several months.

An attempt to fit our data with a single power law leads to a reduced $\chi^2 \cong 1.9$ with 4 d.f. The variability of this source is well established and the use of data taken at different epochs is not entirely satisfactory, however, when X-ray data above 20 keV (refs 4, 5, 10) are included, a similar treatment over the entire energy range leads to a reduced $\chi^2 \cong 2.3$ with 19 d.f. On the other hand, the data can be fitted better with a power law ($\alpha \cong 0.9$) up to 2.5–4 MeV followed by a break and a steeper spectrum ($\alpha = 3.4$–4) at higher energies as suggested by both our data and the upper limits set by SAS2. The resulting reduced χ^2 value for this kind of fit is 0.73 with 19 d.f. Alternatively, our measurements may be represented at energies higher than 200 keV by an exponential of the form

$$dI/dE = (1.6 \pm 0.7)10^{-5} \exp(-E/(2120 \pm 480))$$

photons $cm^{-2}\,s^{-1}\,keV^{-1}$

corresponding to a reduced $\chi^2 \cong 0.5$ with 3 d.f. The data between 10 and 200 keV would then be best fit by a power law of the form

$$dI/dE = (1.1 \pm 0.3)10^{-2}\, E^{-(1.1 \pm 0.1)}$$

photons $cm^{-2}\,s^{-1}\,keV^{-1}$

corresponding to a reduced $\chi^2 \cong 1.1$ with 23 d.f. These two fits are shown in Fig. 2. During our observation, the power output in the range 0.5–5.0 MeV was the highest observed for NGC4151 ($\sim 2 \times 10^{45}$ erg s^{-1} for a distance of 20 Mpc, $H_0 = 50$ km s^{-1} Mpc^{-1}). In the adjacent decades, 50–500 keV and 5–50 MeV, the power was $\sim 2 \times 10^{44}$ and $\sim 6 \times 10^{44}$ erg s^{-1} respectively.

Several models have been proposed to explain the emission from active galaxies up to γ-ray energies. The suggested mechanisms are the inverse Compton scattering of the synchrotron radiation photons[17–20], the accretion onto massive black holes[21–23] or the rotation of magnetised objects (spinar model)[24]. For the non-thermal models, the e-folding energy of the exponential fit (or the cutoff of the power fit) may arise from an equivalent cut-off in the electron spectrum that produces the γ-ray emission or may be due to the opacity of the source for pair production. For a thermal model interpretation, our data suggest a temperature of about 10^{10} K in the active region of the galaxy. An alternative may be the "Penrose Compton Scattering" model proposed by Leiter and Kafatos[25] in the hypothesis of the existence of a massive Kerr black hole at the centre of active galaxies. It is clear that models which predict a cutoff around 500 keV (see ref. 22) are not favoured by our spectral data.

Evidence for low-energy γ-ray emission close to CG135+1

A. Della Ventura*, F. Perotti*, G. Villa*, G. Di Cocco†, R. C. Butler‡, A. J. Dean‡ & R. I. Hayles‡

* Laboratorio di Fisica Cosmica e Tecnologie Relative, CNR, Via Bassini, 15/A, Milan, Italy

The COS-B source CG135+1 (ref. 1) is an extremely interesting object because of its possible identification with the QSO 0241+622. Radio observations have identified a strong point source within 2 arc s (ref. 2) of QSO 0241+622. X-ray emissions have also been observed from this region of the sky by the Uhuru (ref. 3), SAS-3 (ref. 2) and HEAO-A (ref. 4) telescopes. The HEAO-A (A1) data indicate that there are two soft X-ray sources in this region of the sky, H0241+62 which contains the QSO, and H0235+60 which includes the radio source GT0236+61 (ref. 5). The OSO-7 data in the energy range 1–40 keV (ref. 6) and measurements using the high-energy X-ray experiment on Ariel-V between 0.26 and 1.2 MeV (ref. 7) have indicated that the photon emission from this region of the sky is of an extremely hard nature, with a power law spectral index of $\gamma \approx 1.0$. However, the poor angular resolution of these telescopes make it uncertain whether the high-energy X-ray fluxes are due to the same celestial object. We now report the results of a balloon flight carried out on 8 October 1978 from Palestine, Texas, in which the region of the sky including the COS-B source CG135+1 was scanned by the Milan/Southampton telescope (MISO telescope). A 5σ excess in the counting rate of the telescope in the energy range 0.15–20 MeV was observed. The origin of this low-energy γ-ray emission is compatible with the measured position of CG135+1.

The MISO telescope used to study this region of the sky in the low-energy γ-ray region of the spectrum has been described elsewhere[8] and consists of two scintillators, S1 (liquid scintillator) and S2 (sodium iodide), which form the central Compton coincidence detection system. The instrument was sensitive over the energy range 0.15–20 MeV and had an aperture of 3° FWHM in both azimuth and zenith planes for this observation. The telescope was stabilised in both the azimuth and zenith planes with a precision of 20 arc min by means of a two-axis orientation system.

© 1979 Macmillan Journals Ltd

Six drift scans were carried out to survey the region of the sky contained within the coordinate points 2 h 16 min and 3 h 12 min in right ascension and centred on 62° in declination, over the period 6–10 h in universal time. To obtain a reasonable number of scans of the source region during the 4-h observational period available, the telescope was driven in azimuth against the rotation of the sky with a speed of approximately 0.2 deg min^{-1}. The region of the celestial sphere studied encompasses the error boxes of the X- and γ-ray emissions measured by the Uhuru, HEAO-A, SAS-3, OSO-7, Ariel-V and COS-B telescopes. The measurements were made at a mean residual atmospheric pressure of 3.6 mbar with the telescope set at zenith angles in the range 30–34°. The results reported here refer to a preliminary analysis of the integral γ-ray counting rate above 150 KeV, for five passes. Each of the five drift scan measurements was analysed separately so as to eliminate effectively any systematic variations due to zenith and azimuth changes of the background counting rates. The housekeeping data and the spectra from γ-ray calibration sources were studied to ensure that there were no overall measurable changes in the gain of the system during this period. The only source of measurable systematic variation in the background counting rate was due to the change of altitude between 3.5 and 3.9 mbar, and the data have been corrected for this effect.

The background counting rate as a function of pressure was evaluated separately for each drift scan and for each of the three independent counting rate channels (S1, S2, S1.S2). After subtraction of the background a correlation was made between the residual counting rate and the angular distance between the axis of the telescope and the direction of CG135+1. For each pass there was an indication of an excess from the general direction of CG135+1. The results were combined statistically and are shown in Fig. 1. An excess is observed for each of the three independent channels (S1.S2 = 0.65 ± 0.2 c.p.s., S1 = 1.3 ± 0.5 c.p.s., S2 = 2.1 ± 0.6 c.p.s.). The statistical errors quoted here include the uncertainty in the evaluation of the variation of counting rate with residual pressure. Figure 1 also shows the data for the sum of all three channels in which an excess of 5σ is obtained (4.1 ± 0.8 c.p.s.). The solid line in Fig. 1 represents the exposure of the centre of the COS-B error box defined by the aperture of the MISO telescope (3° FWHM). The angular profiles of the excesses can be seen to follow closely the aperture of the MISO telescope.

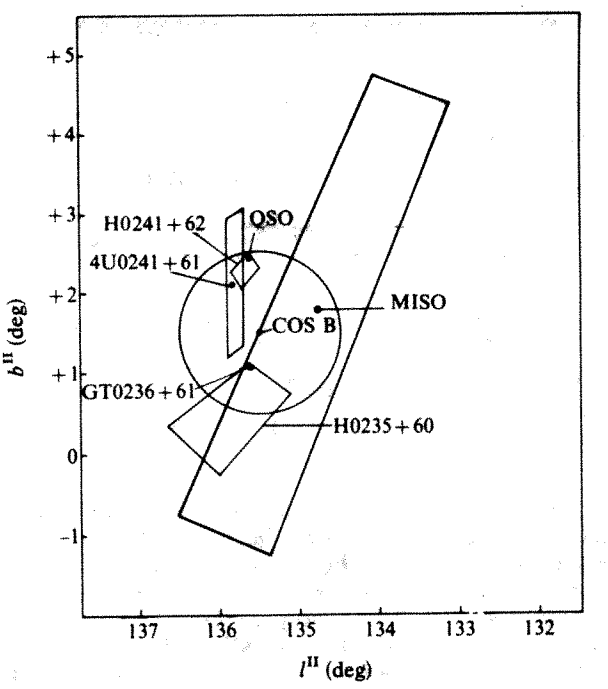

Fig. 2 The MISO error box in galactic coordinates (l^{II} ≡ longitude; b^{II} ≡ latitude) is shown together with other astronomical data. The MISO error box has 68% probability across the scan direction and 100% in the other.

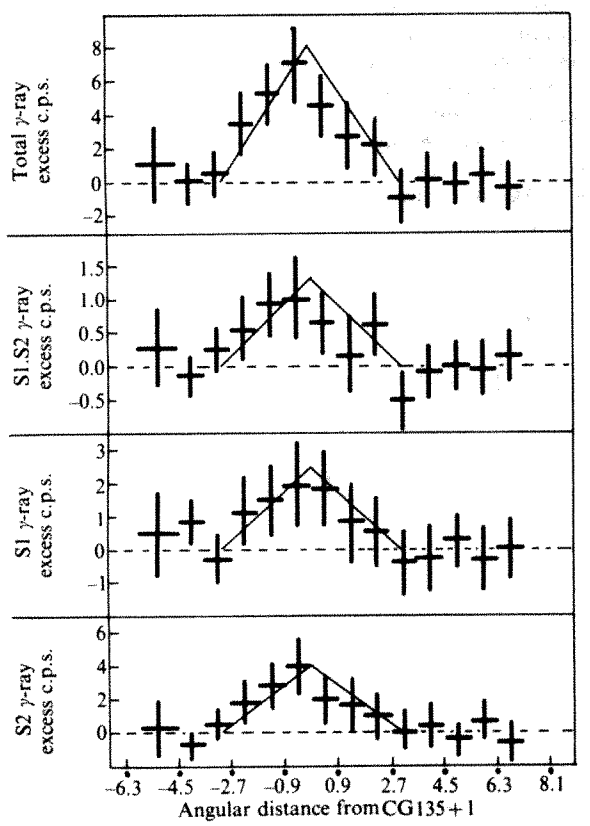

Fig. 1 The γ-ray excess plotted against the angular distance from CG135+1 is shown for the 'singles', the coincidence and the total events. The solid line represents the exposure of the centre of the COS-B error-box defined by the aperture of the MISO telescope (3° FWHM).

Although the data indicate a 0.6° difference between the centroids of the MISO and COS-B emissions, the results are compatible with a common celestial origin. Figure 2 shows the MISO error box in galactic coordinates for the observed γ-ray flux together with other astronomical data taken at different photon energies. As our drift scans were made in one direction only, the limits of our error box are represented by the 1σ points along the direction of scan and by the total aperture of the telescope in the orthogonal direction (100% probability).

If it is assumed that the X-ray and COS-B γ-ray flux measurements originate from the same source object, a steepening of the spectrum is required above 1 MeV. On the basis of our integral counting rate of 4.1 ± 0.8 c.p.s. the spectral change must be close to 1 MeV. Only the full spectral analysis of our data will enable us to say more on the existence of such a change and consequently on the coincidence of the X- and γ-ray emission.

Separation of ^{26}Al and ^{26}Mg isobars by negative ion mass spectrometry

Aluminium-26 (half life 7.16×10^5 yr) is one of the important radioisotopes generated from the spallation by cosmic rays of argon in the Earth's atmosphere. It has been used in studies[1] of the growth rate of manganese nodules from the ocean floor and the constancy of the cosmic-ray intensity in the past[2]. At present, the concentration of ^{26}Al ($^{26}Al/Al\leq10^{-14}$) is measured in large samples by counting the γ rays following the β decay to ^{26}Mg. We have now demonstrated that it is possible to separate ^{26}Al and ^{26}Mg atoms in milligramme samples with a sensitivity for the ratio $^{26}Al/Al$ better than 10^{-14}, using negative ions, a tandem accelerator as a molecular disintegrator, and a mass spectrometer[3]. The measurement of $^{26}Al/^{10}Be$ ratios using the same apparatus and small samples, to provide a several million year chronology[4,5] for oceanic sediments, now seems possible.

The complete separation of the isobars ^{26}Mg and ^{26}Al using negative ion mass spectrometry was shown to be possible in principle by Heinemeier and Hvelplund[6] during measurements on the production of Mg^- and Al^- in sodium vapour. They observed that for 20 keV ions at equilibrium in sodium vapour the ratio of Al^-/Al^+ was 0.10 whereas the ratio of Mg^-/Mg^+ was less than 10^{-6}, implying a highly unstable magnesium negative ion.

Soon after the first detection by atom counting of ^{14}C (half life 5,730 yr) at natural abundances[7], we tried unsuccessfully to use negative ions to detect ^{26}Al at levels of $^{26}Al/Al$ near 10^{-12}. It was realised during several of the early experiments that the problem was due to background from molecular fragments from ions such as $^{12}C^{14}N^-$, and from ^{27}Al positive ions from the injection of $^{27}Al^-$ ions. The abundant ^{27}Al positive ions were present because the mass resolution of the magnet at the ion source was not high enough to reject $^{27}Al^-$ ions when $^{26}Al^-$ ions were injected into the tandem accelerator. These problems can be solved by the addition of an electrostatic analyser, which specifies the ratio of the ion energy and the charge (E/q), to the magnetic analyser after the accelerator which specifies $(M/q)\times(E/q)$. M is the mass of the ions. The use of the combination of electrostatic and magnetic analysis is most successful when M and q do not contain common factors[8].

After the installation of a 10° electrostatic analyser, successful measurements of $^{36}Cl/Cl$ ratios down to 10^{-15} (^{36}Cl half life 3.08×10^5 yr) were made and reported[8]. The apparatus has since been used[9] to measure $^{10}Be/Be$ ratios to below 10^{-14} (^{10}Be half life 1.6×10^6 yr) and $^{36}Cl/Cl$ ratios in meteoritic and other samples[10] to near 10^{-16}. The same apparatus[8] has now been used to detect ^{26}Al. Recently, Raisbeck *et al.*[11] have reported the detection of ^{26}Al by accelerating positive ions to a high energy in a cyclotron and removing all the electrons so that $^{26}Al^{13+}$ and $^{26}Mg^{12+}$ can be completely separated in a magnetic field. A sensitivity for the ratio $^{26}Al/Al$ of 10^{-12} was reached. The complete stripping of the ions solved the problem[12] of detecting ^{26}Al with a cyclotron.

Two samples of aluminium and one of magnesium were prepared for use in the negative ion sputter source of the University of Rochester MP tandem Van de Graaff accelerator. The first sample, of 99.999% pure aluminium, was used for background measurements and the second was machined from an aluminium–magnesium (1%) alloy which had been exposed some years ago to high energy electrons and photons in the beam dump of the 40 MeV Electron Linac at Toronto. The $^{26}Al/Al$ ratio was estimated to be less than 2×10^{-11} by measurements of the γ rays following the β decay of ^{26}Al in a 10-g sample. The magnesium sample was used to increase the sensitivity of the detection system for $^{26}Mg^-$ ions.

The negative ion current of $^{27}Al^-$ from the ion source was about 15 nA during the measurements. This is a low value compared with the current of 1 μA which has been reported from a negative ion sputter source (R. Middleton, personal communication) but it was found to be adequate for the demonstration of the separation of ^{26}Al and ^{26}Mg by negative ion mass spectrometry.

The negative ^{26}Al ions were accelerated to a total energy of 48.17 MeV in the tandem accelerator and the $^{26}Al^{5+}$ ions were analysed by the equipment used previously for ^{36}Cl detection. The dissociation of the molecular ions after charge exchange in the tandem accelerator and the electrostatic analysis provide an efficient way of eliminating such mass 26 molecules as $^{13}C_2$, $^{10}B^{16}O$, and $^{12}C^{14}N$ without the need for high mass resolution. Figure 1 illustrates in a two-parameter plot the clear separation between $^{26}Al^{5+}$ and $^{26}Mg^{5+}$ from the irradiated sample even though there was 1% magnesium in the sample. The measured $^{26}Al^{5+}$ counting rate of (1.5 ± 0.3) c.p.m. and the average analysed $^{27}Al^{5+}$ ion current of 5.3 nA implies a ratio for $^{26}Al/Al$ of $(3.8\pm0.7)\times10^{-12}$ in the irradiated sample. During experiments with the unirradiated pure aluminium sample, no ^{26}Al counts were recorded in a total of 230 min; one count would have implied that an $^{26}Al/Al$ ratio of 10^{-14} was reached. To guard against drifting of the magnets, ion source fluctuations, and other systematic effects, the irradiated aluminium sample was counted immediately before and immediately after the background run on the pure Al sample. The counting rate of the irradiated sample was the same within statistical error for both of these runs, indicating that the system parameters had not changed significantly during the 230 min.

An estimate of the mass of aluminium sputtered during the experiment (1.39 mg) yielded an efficiency for producing negative ions Al^-/Al of about 10^{-3} and a total efficiency for detecting

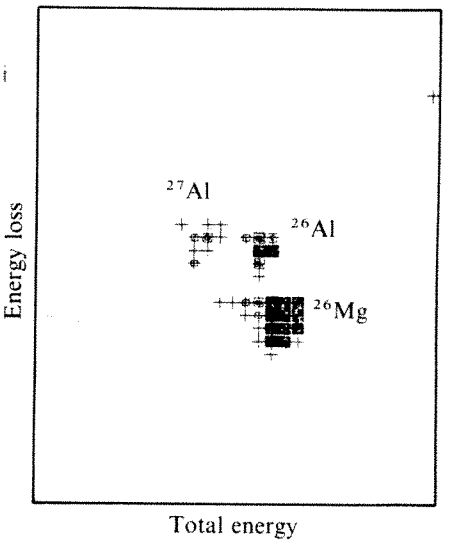

Fig. 1 Counts versus energy loss and total energy from an ionisation counter for an aluminium–magnesium (1%) alloy enriched in ^{26}Al. The few ^{27}Al counts detected at 46.4 MeV are some of the ions from multiple charge exchange in the accelerator tube which gives the required magnetic rigidity. A total of 34 counts corresponding to 48.17 MeV $^{26}Al^{5+}$ and 1,250 counts for $^{26}Mg^{5+}$ were recorded in 23 min. The ^{26}Mg contribution could be reduced substantially by chemical processing of natural samples. No ^{26}Al counts were observed from a pure aluminium sample.

$^{26}Al^{5+}/Al$ from the sample of about 10^{-4}. Even this low efficiency implies that the negative ion method is already superior to the γ-ray counting method for determining $^{26}Al/Al$ ratios below 10^{-12} in samples smaller than about 1 g.

The small current of Al^- ions used for these experiments can be increased by using a more powerful ion source. The efficiency for utilisation of the ^{26}Al atoms and the Al^- current can also be increased by starting with positive sputtered ions and charge exchanging in sodium vapour[6]. In either case currents over 1 μA should make possible measurements of $^{26}Al/Al$ ratios below 10^{-15} in under an hour from samples of aluminium possibly as small as 1 mg. This amount of aluminium can be found in as little as 10 mg of oceanic sediment[4]. The large tandem accelerator used for these demonstration experiments can also, in principle, be replaced by a much smaller tandem accelerator such as those at present under construction specifically for ^{14}C dating[13] as the difference in energy loss (dE/dx) for ^{26}Al and ^{26}Mg, 10.7% in the present experiment, changes to only 7.1% for the smaller machine.

In Fig. 1, a peak corresponding to $^{26}Mg^{5+}$ can also be seen. It was demonstrated that the flux of $^{26}Mg^{5+}$ ions clearly peaked at the terminal voltage used in these measurements and also reached another much larger peak when the tandem terminal voltage was raised 58 ± 8 kV. These $^{26}Mg^{5+}$ ions from the larger peak are from the injection of $^{26}MgH^-$ molecular ions into the accelerator due to the inadequate resolution of the injection magnet ($M/\Delta M \sim 25$) or the breakup of $^{26}MgH_2^-$ into $^{26}MgH^-$ before magnetic analysis. The addition of an electrostatic analyser at the ion source would remove the second source of background. It is worth noting here that the aluminium alloy sample, containing 1% magnesium, enhances the yield of magnesium ions over that of a pure sample.

The $^{26}Mg^{5+}$ ions that appear at the same terminal voltage as the $^{26}Al^{5+}$ ions could be due to the injection of $^{26}Mg^-$ into the accelerator. This, we believe, is an unlikely explanation as the very low limit[6] for the formation of Mg^- can best be explained by a mean lifetime for Mg^- of less than about 10^{-7} s. As the acceleration time for the negative ions in the present experiment is about 10^{-5} s, no Mg^- ions should survive the acceleration. In addition, the efficiency for formation of such metastable ions in a negative sputter ion source is expected to be very low. (R. Middleton, personal communication). The absence of Mg^- ions in the observations of Heinemeier and Hvelplund[6] could also be due to the low binding energy of the electron in Mg^- and to the destruction[14] of Mg^- in the electric analysing field. If this occurs, it can be estimated[14] that the electron binding energy of the negative ion would have to be less than 1 meV. A Mg^- ion with such a low binding energy would be destroyed completely in the high electric fields of the tandem accelerator. These fragile $^{26}Mg^-$ ions could also contribute to the observed $^{26}Mg^{5+}$ ions as a result of multiple charge exchange processes. Further research into the origin of this $^{26}Mg^{5+}$ peak is desirable although it is not expected to interfere with the detection of ^{26}Al in aluminium provided the magnesium abundance is less than 1%.

We thank K. H. Purser for useful discussions and the General Ionex corporation for the loan of the 10° electrostatic analyser. We also thank G. M. Raisbeck and R. Middleton for communicating their unpublished results. The work was supported by the NSERC of Canada and the USNSF. R.P.B. is a Killam Fellow.

A maximum speed of wetting

T. D. Blake & K. J. Ruschak

Research Laboratories, Eastman Kodak Company, Rochester, New York 14650

The wetting (or dewetting) of a solid by a liquid is an integral part of many important processes such as coating, petroleum recovery, distillation and the handling of liquid fuels in low gravity conditions. Several experiments[1–4] have shown that wetting lines (where liquid, air and solid phases meet) which are straight at slow rates of movement over the solid have a sawtooth shape at sufficiently high speeds. We now offer a quantitative explanation for this phenomenon based on the postulate that, for a given system, there is a maximum rate at which wetting can proceed. The consequences of this interpretation are likely to be important, since, in many practical situations, the aim is to maximise the speed of wetting without entraining the displaced phase.

In our experiments, a tape plunges vertically into a pool of liquid. We measure the dynamic contact angle (the angle that the liquid/air interface makes with the moving tape), and we observe the behaviour of the wetting line. At low tape speeds, the wetting line is straight and horizontal. As the speed is increased, the wetting line is pulled below the level of the free liquid surface and the advancing contact angle measured through the liquid increases, reaching 180° at some critical speed U. At tape speeds exceeding U, the wetting line breaks into two or more straight-line segments inclined to the horizontal at an angle ϕ which increases steadily with speed. In other words, the wetting line adopts a sawtooth configuration (Fig. 1). At sufficiently high speeds, air bubbles break off the trailing (deeper) vertices and are entrained into the liquid.

Wetting has been modelled[5] as an adsorption/desorption process in which, as the wetting line advances, molecules adsorbed at the initial solid/fluid interface are randomly but steadily displaced by molecules from the advancing fluid and a new, more or less equilibrium solid/fluid interface is created. This model has been analysed[5,6] using the statistical mechanical theory of transport processes developed by Eyring and co-workers[7], and an expression has been derived relating the dynamic contact angle to the speed of wetting. The form of the

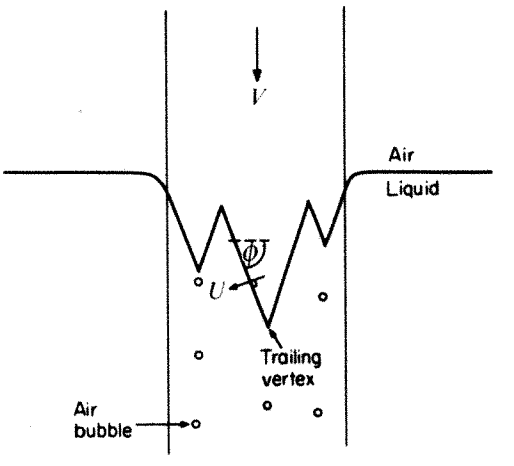

Fig. 1 Schematic representation of the sawtooth wetting line obtained when a tape plunges vertically into a pool of liquid at a speed, V, greater than the maximum speed of wetting, U. The wetting line shows both leading and trailing vertices, with air bubbles entrained at the latter.

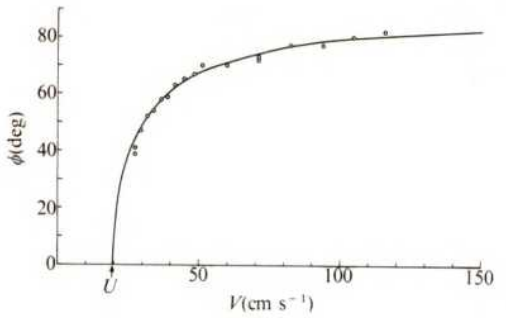

Fig. 2 Measured values of ϕ, the angle of inclination of the wetting line with respect to the horizontal, for a polyester tape (Kodak Estar film base) 5 cm in width and 0.018 cm in thickness plunging at speed V into a nominally 85.6% glycerol/water mixture (viscosity 1.0 P, surface tension 66 dyn cm^{-1}). The theoretical curve was fitted to the data to determine the maximum speed of wetting, $U = 19.4$ cm s^{-1}.

relationship leads to the interesting prediction that there is a maximum speed at which a wetting line can advance normal to itself, that is, a maximum rate of wetting per unit length of wetting line (area/time). This maximum corresponds to a dynamic advancing contact angle of 180°. Conversely, there is a maximum rate of dewetting corresponding to a dynamic receding contact angle of 0°. According to the argument set out below, the breakup of the wetting line into segments slanted from the horizontal is evidence of these speed limitations.

If we suppose that there is a maximum speed, U, for wetting corresponding to a dynamic contact angle of 180°, and if we further suppose that it is the component of tape velocity V normal to the wetting line which is relevant to the wetting process and not the tape velocity itself, then it follows that the tape can be wet at speeds exceeding U only if the wetting line slants from the horizontal at an angle, ϵ, which ensures that the component of tape velocity normal to the wetting line does not exceed U. That is, it follows that

$$\cos \quad \leqslant U/V; \qquad (V \geqslant U)$$

To test this relationship, we have measured as a function of speed for a polyester tape plunging vertically into an aqueous glycerol solution. The data are shown in Fig. 2. The curve through the data is the limit of the above inequality, and so it appears that the wetting line segments adopt the minimum possible inclination such that

$$\cos \quad = U/V; \qquad (V \geqslant U)$$

One consequence of this is that the minimum length of wetting line necessary to wet a unit width of the tape is

$$l = V/U; \qquad (V \geqslant U)$$

and we see that at tape speeds greater than U, the length of the wetting line must increase linearly with tape speed. The value of U obtained by fitting the data in Fig. 2 is 19.4 cm s^{-1}. At this speed, the measured contact angle is 170° rather than 180°, but the agreement with theory is reasonable in the light of experimental uncertainties. The speed at which air bubbles begin to be entrained is 25 cm s^{-1}.

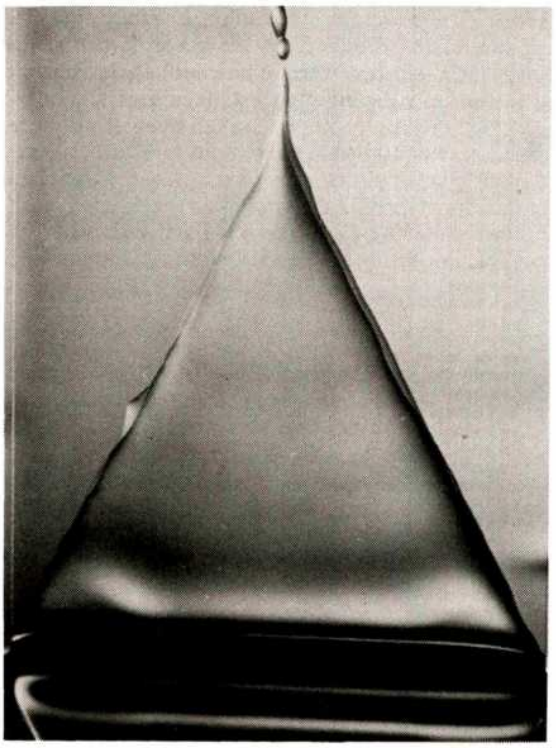

Fig. 3 Example of the sawtooth wetting line that forms when the tape is slowly withdrawn from the liquid at a steady speed greater than the maximum speed of dewetting. The tape is transparent so that two nearly identical triangular tongues of liquid can be distinguished, one on either side of the tape. Methylene blue dye was added to the liquid to increase contrast for the photograph.

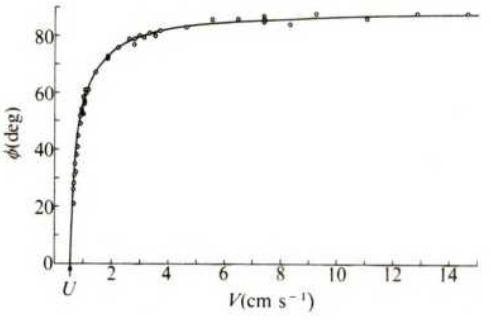

Fig. 4 Measured values of ϕ, the angle of inclination with respect to the horizontal, when the tape is withdrawn from a nominally 72% glycerol/water mixture (viscosity 0.23 P). The theoretical curve was fitted to the data to determine the maximum speed of dewetting, $U = 0.55$ cm s^{-1}.

The same phenomenon occurs when the tape is slowly withdrawn from the pool and the liquid recedes from the tape. Above a tape speed which presumably corresponds to a dynamic contact angle of 0°, the wetting line again consists of at least two straight segments slanted from the horizontal (Fig. 3), and drops or a continuous rivulet of liquid may be entrained from the trailing (higher) vertices. Measured values of the wetting line inclination for one system are shown in Fig. 4. Again, the curve is the limit of the above inequality, where U is the maximum speed of dewetting. The value of U obtained by fitting the data is 0.55 cm s^{-1}, and liquid drops begin to be entrained into the air phase at a speed of 0.8 cm s^{-1}.

The theory presented above predicts that the breakup of the wetting line will be postponed to tape speeds greater than U when the tape does not enter the liquid vertically. Specifically, the wetting line will adopt a sawtooth shape once the tape speed exceeds $U/\cos\psi$, where ψ is the angle of the tape with respect to the vertical. Preliminary experiments in which the tape entered or left the pool at a 45° angle have shown that the expected gain is in fact realised.

The theory also suggests why, with a tape plunging vertically into a pool at a speed greater than U, air bubbles form only at the

trailing vertices of the sawtooth wetting line. Presumably, the curvature of the wetting line is large but finite where two straight-line segments seem to intersect. Thus, the tangent to the wetting line at this apparent vertex is horizontal, and this point of the wetting line will be drawn into the liquid since its speed relative to the tape cannot exceed U. On the other hand, the leading vertices will tend to recede and become trailing vertices, accounting perhaps for the unsteadiness of the sawtooth wetting line when leading vertices are present.

A CO_2-climate sensitivity study with a mathematical model of the global climate

Syukuro Manabe & Ronald J. Stouffer

Geophysical Fluid Dynamics Laboratory/NOAA, Princeton University, Princeton, New Jersey 08540

An increase in the CO_2-content of the atmosphere resulting from man's activity could have a significant effect on the climate in the near future[1]. We describe here some new results from a study of the response of a mathematical model of the climate to an increase in the CO_2-content of the air.

The mathematical model consists of (1) a general circulation model of the atmosphere and (2) a simple mixed layer ocean model with uniform thickness. The atmospheric model predicts the changes of the vertical component of vorticity, divergence, temperature, moisture and surface pressure based on the equations of motion, the thermodynamical equation, and the continuity equations of moisture and mass. The horizontal distributions of these variables are represented by a limited number of spherical harmonics (maximum zonal wavenumber retained is 15)[2,3]. However, the vertical distributions are specified at nine unequally spaced finite difference levels. The model has a global computational domain and realistic geography.

For the computation of solar and terrestrial radiation, the distributions of ozone and cloud cover are prescribed beforehand and the concentration of carbon dioxide is set differently for each experiment, whereas the distribution of water vapour is determined from the prognostic system of water vapour.

Condensation of water vapour is predicted whenever supersaturation is indicated in the computation of the continuity equation of water vapour[4]. Snowfall is predicted when air temperature near the Earth's surface falls below the freezing temperature[5]. Otherwise, rainfall is predicted.

The temperature of continental surface is determined so that it satisfies the requirement of the heat balance[5]. The changes of soil moisture and snow depths are obtained from the budget-computations of water and snow, respectively[5].

The ocean model is a static isothermal water layer of uniform thickness with provision for a sea ice layer. The thickness of 68 m is chosen to ensure that the heat storage associated with the annual cycle of observed sea surface temperature is correctly modelled. Ocean temperature change is computed based on the budget among surface heat fluxes. In the presence of sea ice, the temperature of underlying water is at the freezing point and the heat flux through ice is balanced by the latent heat of freezing and melting at the bottom of the ice. This process, together with the melting at the ice top, sublimation and snowfall, determines the change of ice thickness[6]. The albedo of sea ice and continental snow is assumed to vary between 60 and 70% depending on latitudes. Smaller values are assigned for thin sea ice or thin snow or melting sea ice.

To evaluate the climatic effect from an atmospheric CO_2 increase, we perform two time integrations of the model assuming the normal seasonal insolation cycle and starting from an isothermal, dry and motionless atmosphere with isothermal ocean. The atmospheric CO_2 concentration is set at 300 p.p.m. and 1,200 p.p.m. by volume, respectively (hereafter, these experiments are referred to as $1\times CO_2$ and $4\times CO_2$ experiments). Both cases settle down to a stable climatic condition in about a decade of model time (see Fig. 1). The standard experiment successfully reproduces the observed basic characteristics of geographical and seasonal temperature variation, encouraging the assertion of realism for the model sensitivity to CO_2 changes. The seasonal variations of the model climate discussed below represent mean annual cycles over the last 3-yr periods of both time integrations.

Figure 2*a* shows the seasonal variation of the difference of zonal mean surface air temperature between the $4\times CO_2$ and $1\times CO_2$ atmospheres. In low latitudes, the warming due to the quadrupling of CO_2 content in air is relatively small and depends little on season, whereas in high latitudes, it is generally larger and varies markedly with season particularly in the Northern Hemisphere. Over the Arctic Ocean and its neighbourhood, the warming is at a maximum in early winter and is small in summer. This implies that the range of seasonal variation of surface air temperature in these regions reduces significantly in response to the quadrupling of CO_2 content of air. From the seasonal variations of zonal mean sea ice thickness shown in Fig. 3, it is observed that the sea ice from the $4\times CO_2$ experiment is everywhere less than the sea ice from the $1\times CO_2$ experiment. Therefore it is reasonable to suggest that the $1\times CO_2$ atmosphere is insulated by thicker sea ice from the influence offrlying seawater and has a more continental climate with a larger seasonal variation of temperature than the $4\times CO_2$ atmosphere. Although the poleward retreat of highly reflective snowcover and sea ice is mainly responsible for the relatively large warming

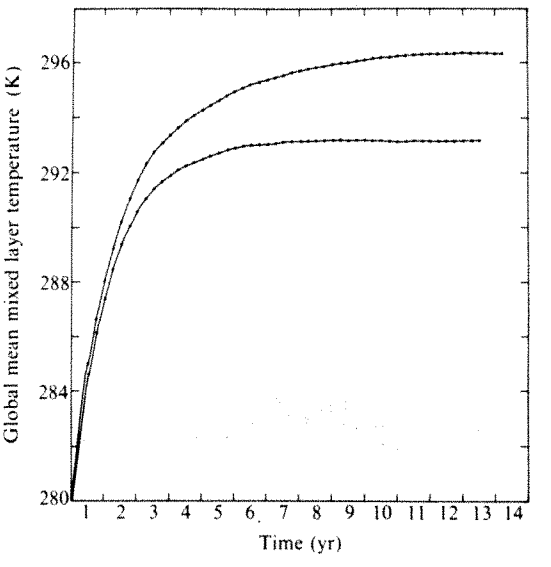

Fig. 1 Time variation of the global mean mixed layer temperature. Lower and upper lines are obtained from the $1\times CO_2$ and $4\times CO_2$ experiment, respectively. The seasonal variation is removed through the application of the running mean procedure over the period of 12 months.

© 1979 Macmillan Journals Ltd

in high latitudes, the change of the thermal insulation effect of sea ice strongly influences the seasonal variation of the warming over the Arctic region.

An analysis of the heat balance over the Arctic Ocean indicates that, in early winter, the flux of sensible heat from the Earth's surface to the atmosphere is much larger in the $4\times CO_2$ case than the $1\times CO_2$ case because of the difference in the magnitude of upward conductive heat flux through sea ice. As the stable stratification in the surface layer of the model atmosphere prevents the sensible heat flux from penetrating into the middle troposphere in high latitudes, the aforementioned difference in sensible heat flux results in the large warming of surface air during early winter. As previously stated, the magnitude of the warming in the summer is much less than the warming in the winter. Because sea ice is thin or absent during summer, the surface albedo reduces significantly and net incoming solar radiation increases from the $1\times CO_2$ to the $4\times CO_2$ case. However, the additional solar radiation is used either for melting upper surface of sea ice or warming the ice-free mixed layer which has a large heat capacity. Thus, the summer warming of the surface air turns out to be relatively small. However, the additional solar energy, which is absorbed during summer in the

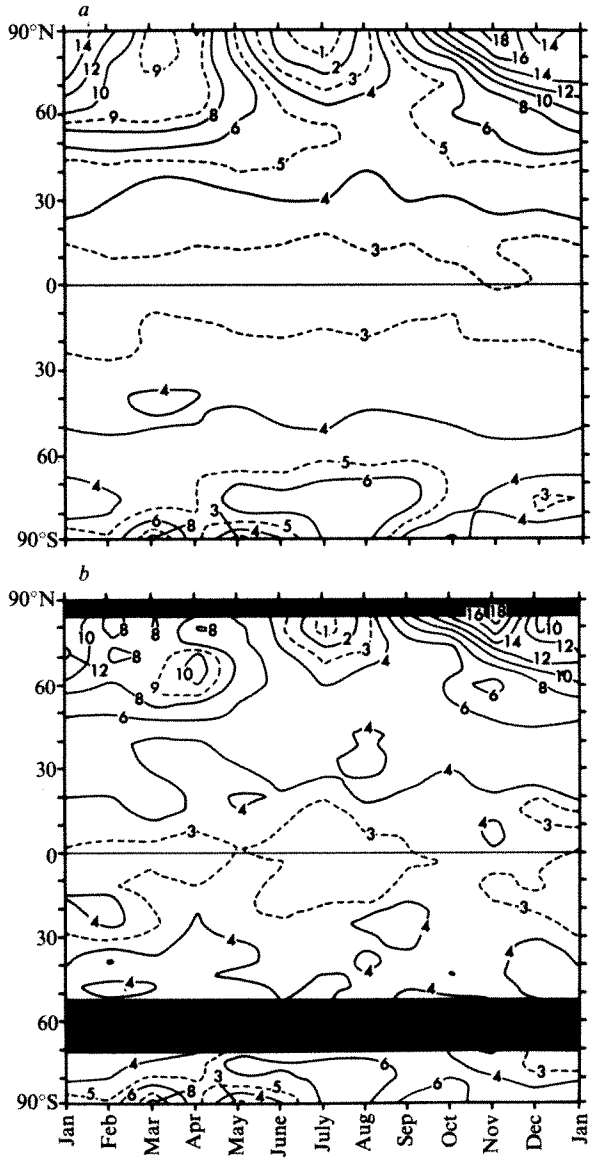

Fig. 2 Latitude–time distributions of the difference in zonal mean surface air temperature between the $4\times CO_2$ and $1\times CO_2$ atmospheres. *a*, Oceans and continents; *b*, continents only. (Positive value indicates warming caused by the quadrupling of CO_2-content of air.)

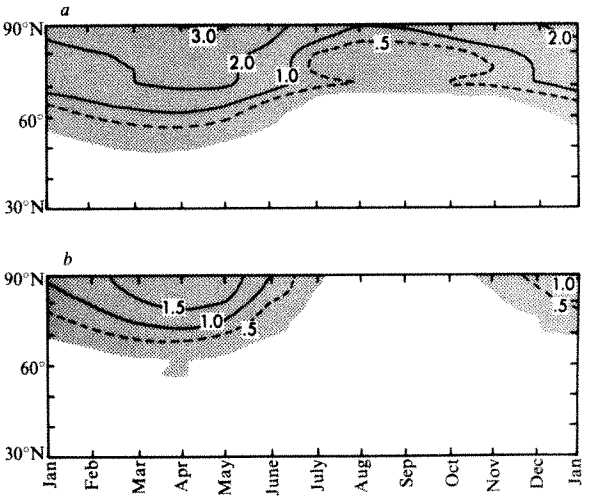

Fig. 3 Latitude–time distributions of zonal mean thickness of sea ice in metres for the Northern Hemisphere oceans. *a*, $1\times CO_2$ experiment; *b*, $4\times CO_2$ experiment. The shading indicates the areas where sea ice thickness is more than 0.1 m.

$4\times CO_2$ case, delays the appearance of sea ice or reduces its thickness. This increases the conductive heat flux through ice in early winter when the air–sea temperature difference becomes large, thereby enhancing the warming of the surface atmospheric layer in early winter.

The seasonal variation of the difference in the surface air temperature between the two experiments over the model continents is significantly different from the variation over the model oceans. According to Fig. 2*b*, which shows the latitude–time distribution of the difference in zonal mean surface air temperature over continents, the CO_2-warming in high latitudes is at a maximum in early winter, being influenced by the large warming over the Arctic Ocean discussed above. However, Fig. 2*b* also indicates a secondary centre of relatively large warming around 65°N in April. This results from a large reduction in surface albedo in spring when the insolation acquires a near-maximum intensity. The reduction of snow cover area from the $1\times CO_2$ to the $4\times CO_2$ experiment is responsible for this albedo difference.

This study shows two interacting mechanisms, each acting to produce its own sensitivity maximum. The maximum warming of the early winter over the Arctic Ocean and its neighbourhood is caused by the change in sea ice thickness, and the relatively large warming over the continents in spring is produced by snow albedo feedback. Therefore, it seems reasonable that simpler climate models with the albedo feedback mechanism but without the thermal insulation effect of sea ice would have the largest sensitivity in the early summer[7,8]. Using his simple model, Sellers[9] found an early winter maximum sensitivity at ~80°N. This winter maximum, however, apparently results from different mechanisms.

Table 1 summarises the area mean changes of the annual mean surface air temperature of the model atmosphere which occurs in response to the quadrupling of CO_2 content in air. According to Table 1, the global mean warming of the model

Table 1 The surface air temperature difference between the $4\times CO_2$ and $1\times CO_2$ atmosphere in °C

	Northern Hemisphere	Southern Hemisphere	Global domain
Difference	4.5	3.6	4.1

Positive value indicates warming caused by the quadrupling of CO_2-content of air.

atmosphere is ~4°C. This result suggests that the warming caused by the doubling of CO_2-content would be ~2°C. This is significantly less than the warming which is estimated by the general circulation model of Manabe and Wetherald[10] with idealised geography and without seasonal variation of insolation. Table 1 also reveals that the area mean warming of the Northern Hemisphere is significantly larger than that of the Southern Hemisphere. This interhemispheric difference results partly from the smallness of the snow albedo–feedback effect over the Antarctic ice sheet where surface albedo differs little between the $1 \times CO_2$ and $4 \times CO_2$-experiments.

In view of the assumption of fixed cloudiness and various simplifications contained in the sea ice modelling, the quantitative aspect of the present results should be received with caution. However, this study suggests that the warming of the atmosphere in response to an increase in CO_2-content of the air will have significant seasonal and interhemispheric asymmetries.

Carbon disulphide and carbonyl sulphide from biogenic sources and their contributions to the global sulphur cycle

V. P. Aneja, J. H. Overton & L. T. Cupitt

Environmental Sciences Center, Northrop Services Incorporated, Research Triangle Park, North Carolina 27709

J. L. Durham & W. E. Wilson

US Environmental Protection Agency, Research Triangle Park, North Carolina 27711

Estimates of the magnitude of biogenic sulphur emissions range from ~70% of the total atmospheric sulphur burden[1–7], and the chemical nature of the emissions has not been clearly established. Conway[1] speculated that the principal volatile biogenic component of the sulphur cycle was hydrogen sulphide (H_2S) whereas Lovelock *et al.*[8] and Rasmussen[9] have suggested that dimethyl sulphide (DMS) contributes to the apparent source deficits. Aneja *et al.*[10] have shown that both H_2S and DMS are emitted from saltmarshes. Other volatile sulphur compounds which may contribute to the sulphur burden of the atmosphere include methyl mercaptan (CH_3SH)[11,12], dimethyl disulphide ($(CH_3)_2S_2$)[11,12], carbonyl sulphide (COS)[13] and carbon disulphide (CS_2)[14,15]. We report here the discovery of CS_2 and COS emanating from a saltmarsh and estimate their emission rates using emission flux reactor and bag chamber techniques. The species CS_2 and COS are relatively inert in the troposphere, so may be assumed to penetrate to the stratosphere, where they may be photolysed to form the sulphur dioxide (SO_2) and sulphates (SO_4^{2-}) known to be present in the stratosphere. Based on the measured fluxes, we show that the emissions from marshes are important to the sulphate aerosol burden ($\leq$19%) of the stratosphere, but not important for the tropospheric sulphur burden ($\leq$0.2%).

An emission flux reactor (chamber) was used for measuring Earth–atmosphere fluxes of biogenic sulphur compounds. The chamber technique has high sensitivity for flux measurement without the necessity of measuring very low concentrations. In addition, gas residence times in the emission flux reactor are of the order of minutes so that chemical transformations between emission and analysis may be minimised. The chamber used by Aneja[11] and Hill *et al.*[12] was modified by making the walls from 5-mil (~0.13 mm) thick FEP Teflon supported by an exterior aluminium frame. This design was chosen to provide negligible attenuation of ambient light.

The analytical instrument used was a gas chromatograph (Tracor 270HA) equipped with a flame photometric detector. A 394-nm interference filter made the detector sensitive to sulphur compounds. A 36-foot (~11 m) FEP Teflon column ($\frac{1}{8}$ inch (0.32 cm) o.d.) packed with 40–60 mesh Teflon coated with 5% polyphenyl ether (PPE) and 0.5% phosphoric acid was used at 50 °C to separate gaseous sulphur species[17]. The carrier gas was nitrogen with a flow rate of ~81 ml min^{-1}. The retention time for CS_2 in these conditions is ~14 min which allows a good separation from $H_2S + COS$ (1.5 min), SO_2 (3.1 min), and CH_3SH (5.0 min). The overlapping DMS (12.2 min) and CS_2 peaks were manually resolved into separate contributions. This column did not resolve H_2S and COS, so these species were separated by incorporating a second 19-foot (5.8 m) FEP Teflon column ($\frac{1}{8}$ inch (0.32 cm) o.d.) packed with 50/80 mesh Porapak QS in parallel with the first. The two columns were incorporated in the flow lines separately by a pneumatically controlled switching system. The carrier gas for the second column was nitrogen with a flow rate of ~40 ml min^{-1}. The retention time for COS in these conditions is ~8 min, which allows a good separation from H_2S (retention time ~5.5 min); however, this column retained CS_2. The gas chromatograph was calibrated for both columns in the laboratory and in the field using a dilution system and bag samples.

Intensive measurements were made for biogenic sulphur species at Cox's Landing, Long Beach, North Carolina; and at Cedar Island Wildlife Refuge, North Carolina, which are saltmarshes on the east coast of the US (Fig. 1). Experiments were performed during late summer at both locations. At Cox's Landing, 12 different test sites were selected. At each test site, two identical emission flux reactors were placed next to each other. One was flushed with pure gaseous nitrogen (de-aerated) and the other with ambient air (aerated). This was done to gain information on the oxygen-depleted gaseous environment, as well as to maintain the integrity of the emitted sulphur compounds in the de-aerated case. Sampling was done over mud flats, over regions close to marsh grass where the vegetation was decaying, and over marsh grass (*Spartina alterniflora*) clipped to about 1 inch above ground level. Time-integrated bag samples of the effluent gas from the emission flux reactor were collected every 30 min. These bag samples were analysed within 30 min for various gaseous sulphur species in a controlled environment mobile laboratory parked at the edge of the marsh. All the experiments at Cox's landing were performed to study the emission fluxes of CS_2 for diurnal and tidal variations. During the experiments, the ambient temperature ranged between 19.1 and 33.4 °C, sediment temperature with the tide out ranged from 24.2 to 32.6 °C, and the water temperature with the tide in was between 23.8 and 31.2 °C.

Figure 2*a* is a typical chromatogram (using the PPE column) of sulphur gases emitted from the saltmarsh. It indicates the presence and identity of CS_2 and various other biogenic sulphur species.

The average emission rates of CS_2 at the various types of test sites are given in Table 1. In 20 of the 172 aerated runs, CS_2 was detected; and CS_2 appeared only one in the de-aerated case. All of the data in Table 1 are for the aerated case. The CS_2 emission rates in the mud flat zone in the presence and absence of a water column for varying light conditions were less than 0.05 gS m^{-2} yr^{-1} (this is the emission rate based on the lowest detectable CS_2 concentration). CS_2 is also evolved over and in

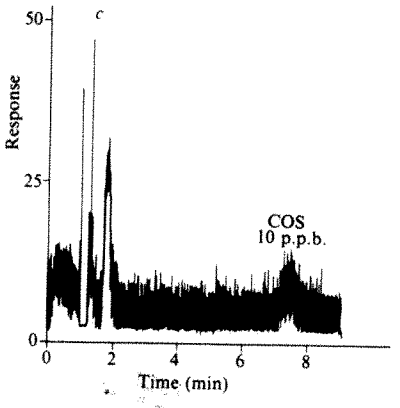

Fig. 2 *a*, Chromatogram of volatile sulphur compounds from *Spartina* zone. The chromatogram was obtained at Cox's Landing using the PPE column and a nonlinear sulphur-specific flame photometric detector (FPD). *b*, Chromatogram of volatile sulphur compounds obtained from enclosed *Spartina* stem. The chromatogram was obtained at Cox's Landing using the PPE column and a nonlinear sulphur-specific FPD. *c*, Chromatogram of volatile sulphur compounds resolved on a Porapak QS column. The sample was obtained at Cedar Island.

Table 1 Emission rate measurements of CS_2

Test site characteristic	Mean emission rate of all runs, gS m^{-2} yr^{-1} (no. of runs)	Mean of runs with emission rate greater than detectable limit*‡, gS m^{-2} yr^{-1} (no. of runs)
Over mud flat zone (direct emission rate measurement*) August 1977	<0.05 (100)	— (0)
Over decaying *Spartina* zone (direct emission rate measurement*) August 1977	~0.04 (61)	0.19±0.07 (13)
Over *Spartina alterniflora* zone (direct emission rate measurement*) August 1977	0.13 (11)	0.21±0.06 (7)
Enclosed single *Spartina alterniflora* plant (indirect emission rate measurement†) July 1978	0.20 (10)	0.20±0.09 (10)

* Direct emission rate $n = (F \cdot \Delta C/A)$, where F = steady volumetric flow rate of gas through the chamber; ΔC = concentration increase; A = area of emitting surface covered by the chamber. Based on the CS_2 detectable limit of the instrument, the corresponding emission rate is <0.05 gS m^{-2} yr^{-1}, and the CS_2 analytical error is ±3% of the estimated value.

† Indirect emission rate $n = (S \cdot \Delta C \cdot V)/t \times 8{,}760$, where S = no. of stems per m^2; ΔC = concentration increase, parts per 10^9; V = volume of chamber (1.96×10^{-3} m^3); t = time of enclosure (h). For this measurement, the CS_2 detectable limit is 0.017 gS m^{-2} yr^{-1} and the CS_2 analytical error is ±3% of the estimated value.

‡ Values are given ±s.d.

the vicinity of *Spartina alterniflora* under the aerated emission flux reactor in the presence and absence of a water column and the fluxes range from <0.05 to ~0.3 gS m^{-2} yr^{-1} (Table 1). CS_2 may be formed at a juncture of the carbon and sulphur cycles by either biogenic or chemical activity. These observations show that CS_2 is certainly produced in an aerated environment, and that it may be formed in a de-aerated environment. Lovelock[15] has observed that CS_2 can originate in anaerobic conditions on the sea floor, while, in the *Spartina alterniflora* zone, we observe it more often in aerobic conditions. The reasons for the differences between the aerated and de-aerated chamber runs are not yet known.

These observations suggest that *Spartina alterniflora* plants may be associated with the production of CS_2. This association is also supported by the results of an indicrect method of estimating gasous sulphur flux (see ref. 18 for the enclosure method). A single stem was enclosed for ~6 h in a Pyrex glass cylindrical chamber of ~1.96 litre volume (~100 cm long and ~5 cm i.d.). Samples were collected during day and night. Ten such experiments were performed and *in situ* syringe samples (one for each stem) were withdrawn from the glass chambers and analysed on the gas chromatograph. In all cases large quantities of CS_2 were observed (see Fig. 2*b* and Table 1).

Seneca *et al.*[19] have determined the stem density in North Carolina coastal saltmarshes to be ~200±25 stems m^{-2}. Based on this result, the emission rate of CS_2 from *Spartina alterniflora* stems is estimated to be ~0.2 gS m^{-2} yr^{-1} (Table 1). Note that this indirect emission rate measurement leads to emission rate values similar to those obtained by direct flux measurement over the *Spartina* zone (Table 1).

At Cedar Island three different test sites were selected over *Spartina alterniflora* and mud flat zones. At each test site the emission flux reactor was used in the aerated mode only. All the experiments described (Table 2) were performed to study the emission fluxes of COS. It establishes the presence and identity of COS as indicated by the gas chromatogram in Fig. 2*c*. The indirect method of estimating gaseous sulphur flux revealed no release of COS from *Spartina alterniflora* plants.

To estimate the per cent of biogenic contribution of CS_2 and COS to the global tropospheric sulphur cycle, we assumed that all marshes are completely made up of *Spartina alterniflora* and that they emit uniformly. We took the total marsh area[20] as 3.8×10^5 km^2, and assumed that 100×10^6 tons of gaseous sulphur are emitted per year from the biosphere by natural processes[4]. Based on our CS_2 indirect and COS direct emission rates (~0.2 gS m^{-2} yr^{-1} and 0.03 gS m^{-2} yr^{-1}, respectively) and the above assumptions, the contribution of CS_2 and COS from marshes is a small portion, <0.07% and 0.09%, respectively, of the biogenic sulphur. Obviously, more work is needed to characterise the global processes adequately.

We also estimated the contributions of CS_2 and COS emissions to the stratospheric sulphate aerosol layer. According to Crutzen's[16] estimate, a flux of ~1.8×10^{-4} gS m^{-2} yr^{-1} into the stratosphere will account for the entire stratospheric sulphate aerosol layer. Applying Junge's[21] one-dimensional eddy diffusion model to the troposphere, and using the present CS_2 and COS average emission rate for global marshes and CS_2 and COS atmospheric lifetimes[14] of 1 yr and 20 yr respectively, an upper limit to the contributions can be made by assuming zero CS_2 and COS concentrations at 15 km height (average Junge aerosol layer ~20 km). The upper limit contributions are 8% for CS_2 and 11% for COS. However, if land plants emit CS_2 at rates comparable to those measured for *Spartina alterniflora* the biogenic emissions of CS_2 could account for the entire Junge layer. Experiments are under way to test for CS_2 emissions for land vegetation.

We thank E. Corse, R. Whitkus, M. Richards, and H. Sher of NSI for assistance.

Table 2 Emission rate measurements of COS

Test site characteristic	Mean emission rate of all runs, gS m^{-2} yr^{-1} (no. of runs)	Mean of runs with emission rate greater than detectable limit‡ gS m^{-2} yr^{-1} (no. of runs)
Over mud flat zone (direct emission rate measurement*) July 1978	0.05 (2)	0.05±0.01 (2)
Over decaying *Spartina* zone (direct emission rate measurement*) July 1978	0.01 (2)	0.02 (1)
Over *Spartina alterniflora* zone (direct emission rate measurement*) July 1978	0.03 (7)	0.04±0.03 (6)
Enclosed single *Spartina alterniflora* plant (indirect emission rate measurement†) July 1978	<0.01* (10)	<0.01* (0)

* Based on the COS detectable limit of the instrument, the corresponding emission rate is <0.01 gS m^{-2} yr^{-1} and the COS analytical error is ±20% of the estimated value. See Table 1.

Tidal flexure of ice shelves measured by tiltmeter

S. N. Stephenson & C. S. M. Doake

British Antarctic Survey, Natural Environment Research Council, Madingley Road, Cambridge, UK

J. A. C. Horsfall

Department of Geodesy and Geophysics, University of Cambridge, Madingley Rise, Cambridge, UK

A new design of tiltmeter has been used to measure the tidal bending of the Ronne Ice Shelf, Antarctica. By this means the point at which the ice sheet leaves the land and starts floating on the sea has been defined to within 600 m. Monitoring this position in future should give an indication of the state of balance of the West Antarctic ice sheet, often considered[1] to be unstable even if not actually disintegrating. The hydrostatic level meter is light and simple and can operate unattended while recording continuously for periods of several weeks. Observations at eight different sites on Rutford Ice Stream (Fig. 1) gave tidal records on ice more than 1,700 m thick and at points up to 600 km from the nearest open sea.

Antarctic ice shelves are floating ice sheets varying in thickness from 100 m to more than 1,700 m. They rise and fall on the ocean tide, bending over a narrow region where they join the grounded ice sheet. The variation in theoretical surface elevation profiles over the duration of a tidal cycle have been derived [1,2] for several constitutive laws, but there have been no published measurements of tidal changes in profiles. The reason is partly because there are crevasse fields in many hinge zones and partly because of the lack of a suitable measurement technique. Gravimeters, strain meters and optical methods all have serious drawbacks because of their cost or their logistic and manpower requirements. The hydrostatic level meter, however, is a stable, continuously recording and relatively cheap instrument that, once placed in a shallow trench in the snow surface to reduce temperature and atmospheric effects, can operate unattended for long periods. For a short base length (5 m in our case) the instrument will measure changes in surface gradient which can be integrated along a transect to obtain a surface profile.

There are several reasons for wanting to measure tidal flexing. Actual profiles can be compared with theoretical[1,2] profiles in order to deduce the most appropriate constitutive law. There is evidence that the crystal orientation fabric of the ice can be significantly altered as it passes across the hinge zone[3]. A knowledge of strain rates is necessary for calculating the development of the fabric[4] and its effect on the flow law. Plastic deformation of ice in the bending zone dissipates tidal energy[5], but for a precise estimate both the constitutive law and the region over which bending occurs must be known. By measuring tidal constants it will be possible to study the interaction of tide not only with the main body of an ice shelf[6] but also with its grounding region. The stability of ice sheets grounded below sea level is thought to be controlled by the shielding effect of ice shelves[7]; tidal flexing may effect the dynamic behaviour in the hinge zone and may thus be an important consideration in the possible disintegration of the West Antarctic ice sheet[8]. By locating accurately the position of the grounding line any future changes can easily be monitored.

An instrument was required which would measure tilts of the ice surface as small as 10^{-6} radians with as large a dynamic range as possible. Tiltmeters currently available were considered unsuitable mainly because of the difficulty of mounting them on ice; all were intended to be installed in boreholes to give the necessary stability. In most materials and particularly in ice, such a hole takes several days to become mechanically and dimensionally stable. We therefore decided to use an instrument which could measure the height difference between two separated points on the glacier surface. The hydrostatic level meter consists of two vessels containing a liquid connected by a tube so that the liquid surface forms a gravitational potential (Fig. 2); a second tube connects the air space above the liquid at each end. Instruments of this form have been used for many purposes, for example for precision levelling on Hawaii[9] but the liquid height has been read by direct optical means and attempts to make an automatically recording instrument using floats with displacement transducers, ultra-sonic measurement of fluid level, or mercury capicitance transducers have only been a success in laboratory conditions.

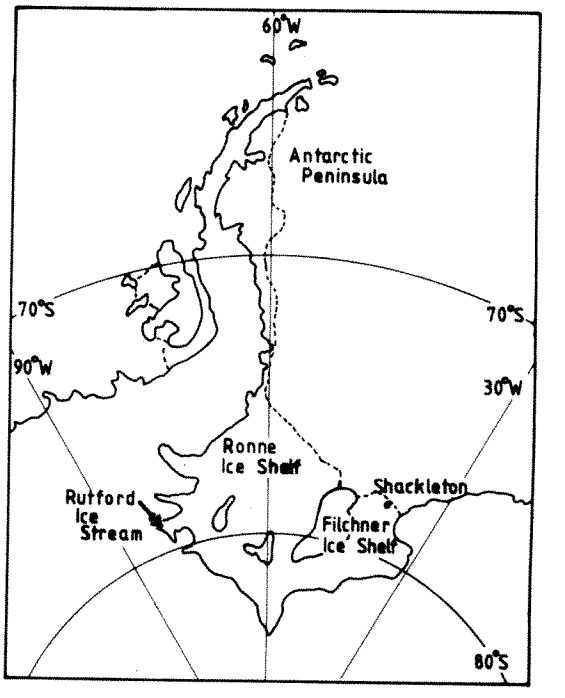

Fig. 1 Map showing location of tiltmeter sites.

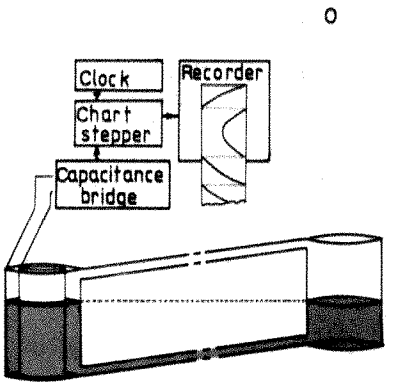

Fig. 2 Hydrostatic level meter with concentric cylinder transducer to measure liquid height.

To monitor liquid height the new instrument uses a sensitive capacitance bridge to measure the electrical capacitance between two concentric cylinders containing a liquid of known dielectric constant. Rather severe constraints on the electrical and physical behaviour of the liquid are all met by an inert fluorocarbon, ICI MFL 18. The liquid and air vent tubes are $\frac{1}{4}$-inch diameter silicone rubber tubing which does not become stiff at low temperatures. The length of the instrument was chosen to be 5 m as a compromise between the height difference signal and ease of handling; the dimensions of the measuring capacitor give a total usable range of 100 mm representing a tilt of $\pm 10^{-2}$ radians. The electronic system is the same as that of Horsfall and King's geophysical tiltmeter[10] and has a resolution of 10^{-6} in liquid height, representing tilts of 2×10^{-7} radians. It consists of a transducer drive unit, a chart stepper, a chart recorder and a quartz clock time unit; by expanding the range of the recorder by a factor of 25, the chart stepper allows full advantage to be taken of the wide range of the instrument. The complete system has a power consumption of less than 10 mA at 12 V and may therefore be run from either low temperature dry cells or, as in this experiment, from a vehicle battery.

Eight tiltmeter sites were chosen along a stake scheme which ran down the approximate centre line of the ice stream. The upper two sites showed no response to tidal bending while the third, 600 m downstream, and the rest all gave strong tidal records. The settling time until equilibrium was reached was small because the end units are light and because the instrument measures a height difference. At one site which showed no tidal movement it was possible to measure a drift which lasted for only 4 h. The shortest recording period at any of the sites which gave tidal records was 3 days. The amplitude of the vertical movement, about 10 mm, had not appreciably died away at the end site, showing that the flexure zone extended more than 6 km. The distribution of amplitudes did not show the pattern expected from considering a simple hinge line. This suggests that the glacier side walls influence the flexing, or that there are locally grounded regions within the flexing zone downstream of the first grounding line. The measured curves can be compared with a tidal prediction (Fig. 3) based on data for the four main tidal constituents (O_1, K_1, M_2, S_2) obtained at Shackleton Base on the Filchner Ice Shelf in 1957 by Pratt[11]. Although the Rutford Ice Stream is nearly 1,000 km from Shackleton Base and differs in longitude by 43°, the times of high and low water match surprisingly well.

The ease by which tidal measurements can be taken using the new tiltmeter means that the interaction between ice shelves and tides can be studied in detail. In particular, our results show that the position of the grounding line can be found with sufficient accuracy for any changes to become quickly apparent when monitored in future.

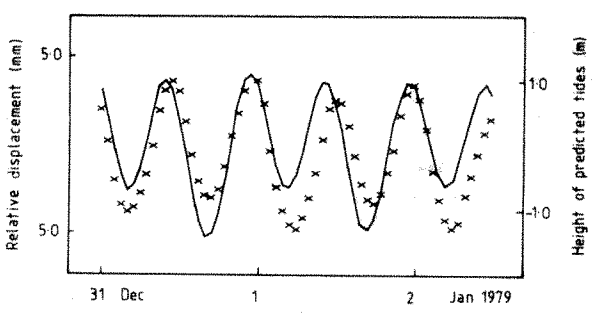

Fig. 3 Comparison between tiltmeter record (crosses) and predicted tide (solid line).

A geologically meaningless Rb–Sr total rock isochron

D. Field

Department of Geology, University of Nottingham, Nottingham, UK

A. Råheim

Mineralogisk-Geologisk Museum, Sars Gate 1, Oslo, Norway

A major objective in total rock Rb–Sr isotope studies of relatively homogeneous igneous or high-grade metamorphic gneisses is to obtain as wide a range of $^{87}Rb/^{86}Sr$ ratios as possible, so that the resultant isochron may be well defined[1]. This is often achieved by collecting samples at some distance from each other. Recent studies[2–6] have shown that primary Rb–Sr isotopic systems can be profoundly disturbed, and even completely reset, in response even to low-grade secondary deformations and/or mineral alterations, and in three cases[2–4] isochron diagrams based on regionally collected samples have been shown to yield linear arrays corresponding to apparent ages intermediate between the true ages of the primary and secondary events. The evidence we present here shows that it is also possible for well defined intermediate isochron apparent ages to be produced where this sampling technique is used on rock suites which show evidence of only minor secondary alteration effects. An isochron so produced is geologically meaningless, that is, the apparent age is unrelated to any geological event.

We have recently presented the results of a detailed Rb–Sr isotope investigation of a high-grade, acid-intermediate, charnockitic orthogneiss suite at Arendal, southern Norway[4]. Eight series of samples, collected from individual outcrops, yielded apparent ages in two distinct groups, at ~1,540 Myr and ~1,060 Myr. The major conclusions were that the ~1,540 Myr age (best estimate 1,536 ± 26 Myr; $^{87}Sr/^{86}Sr$ initial ratio

F409	150.5	104.4	4.2302	0.78683±0.00012
F509	235.0	79.1	8.7302	0.87085±0.00014

Rb, Sr and Rb/Sr determined by X-ray fluorescence[9]. Precision of $^{87}Rb/^{86}Sr$ is ±1%. Precisions of $^{87}Sr/^{86}Sr$ quoted as 2σ standard error of mean. Details of location, petrography and analytical procedures presented previously[4].

0.70345±0.00014) reflects the formation of the high-grade charnockite mineralogy (quartz-plagioclase-orthopyroxene± K-feldspar, hornblende, clinopyroxene, biotite, garnet) and that there was subsequent disturbance of the total rock isotopic systems during a low-grade event which occurred at the same time as the intrusion of undeformed granite sheets and pegmatite dikes at 1,063±20 Myr. The only petrographically visible effects of this superimposed low-grade event are (1) partial, and often variable, alteration of orthopyroxenes to chlorite and/or serpentine, (2) minor corrosion of pre-existing biotite, and (3) incipient turbidity within some plagioclases. These mineral alterations were initiated along narrow (≤1 mm) irregularly spaced cracks which facilitated the open system behaviour. The superimposed event caused resetting to the younger age not only of all primary mineral systems investigated (plagioclase, K-feldspar, biotite, in four localities), but also of the 1–2 kg rock systems at those localities (three) where the mineral alterations are most pronounced. Both the secondary total rock ages, and all mineral ages, fall within error of the 1,063±20 Myr age obtained for one of the intrusive granite sheets. For each of the localities which suffered resetting of the total rock systems, all samples with $^{87}Rb/^{86}Sr \geq 0.8$ were displaced below the original 1,536 Myr isochron. This showed that the resetting process did not involve a simple rehomogenisation of the Rb–Sr systems within individual outcrops, but that there was a systematic change in $^{87}Rb/^{86}Sr$ and/or $^{87}Sr/^{86}Sr$.

The results presented here (Table 1) refer to a group of regionally-collected samples from the same charnockite body. They have been taken from an area of 1 km^2 at the northern end of the island of Flostaøya[4]; the area centres on one of the previously described localities (no. 4) which has suffered isotopic resetting during the secondary event. Both series of data are plotted in Fig. 1, together with the mineral data for sample 4.4. The data for the samples from locality 4 (a 10-m road cut) were presented in the earlier study[4].

The five total rock samples from locality 4 give a good fit isochron age of 1,075±122 Myr with a value for the mean square of the weighted deviates (MSWD)[7] of 1.10; the mineral (plagioclase, K-feldspar, biotite) + host rock data for sample 4.4 yield 1,036±20 Myr (MSWD = 2.69). When the mineral data are regressed together with those for all of the rocks from this locality, an eight-point isochron age of 1,035±9 Myr (MSWD = 1.19) is obtained (Fig. 1). These ages are all within error (2σ) of the 1,063±20 Myr age for the intrusive granite sheet, and they correlate with the low-grade superimposed event. The regionally collected samples define a good-fit apparent age of 1,264± 25 Myr. An MSWD of 1.58 indicates that the scatter about the isochron can be assigned to experimental error. The problem is that this good-fit 1,264 Myr isochron apparent age correlates with neither the primary (~1,540 Myr) nor the secondary (~1,060 Myr) event, and there is no geological evidence for an intermediate event to which it might relate. We interpret the 1,264±25 Myr isochron 'age' as being geologically meaningless.

A key aspect of these data is that a combination of the locality 4 samples with the regional samples yields an apparent age of 1,259±24 Myr (Fig. 1), which is virtually identical to that given by the regionally collected samples alone; the MSWD value, although slightly higher at 2.07, is still indicative of reasonable fit. The implication is obvious: in a regionally-based sampling programme, any individual sample collected from locality 4 would plot on, or very close to, the geologically meaningless isochron, despite the fact that the within-locality age is quite different. This situation arises because of the relatively small dispersion of $^{87}Rb/^{86}Sr$ at locality 4.

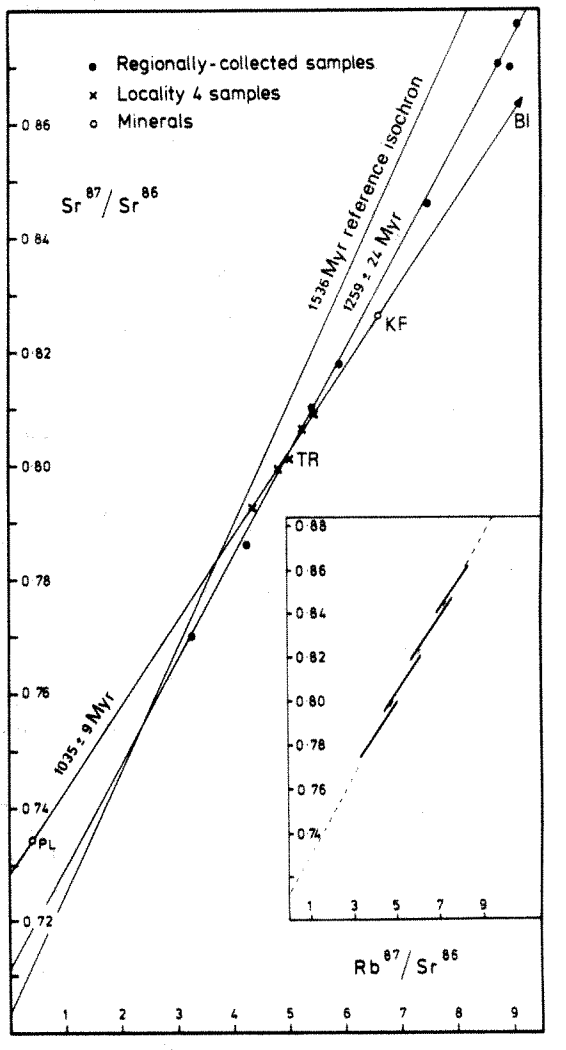

Fig. 1 Rb–Sr isochron diagram for regionally collected rock samples (●), and minerals (○) and rocks (×) from a single locality (no. 4). The 1,536±26 Myr reference isochron (IR = 0.70345± 0.00014) relates to the formation of the high grade charnockite mineralogy[4]. The 1,035±9 Myr isochron age (MSWD = 1.19; IR = 0.72862±0.00024) is that given by a combination of rocks and minerals at locality 4. The 1,259±0.00024 Myr apparent age (MSWD = 2.07; IR = 0.71189±0.00182) is that given by a combination of the regionally collected ($n = 8$) and locality 4 ($n = 5$) rock samples. By themselves the regionally collected samples define an apparent age of 1,264±25 Myr (MSWD = 1.58; IR = 0.71107±0.00194). The data have been regressed by the method of York[10]. The decay constant used is 1.42×10^{-11} yr^{-1}. All errors are quoted as $\pm 2\sigma$. The inset represents the probable relationship between the geologically meaningless 1,264 Myr isochron (dashed line) and within-locality sub-isochrons (~1,060 Myr, solid lines). The latter would reflect the true age of the superimposed event.

All of the data points for the regionally-collected samples plot below the 1,536 Myr primary reference isochron (Fig. 1). Because (1) the displacement is in the same sense as that shown by samples with $^{87}Rb/^{86}Sr > 0.8$ from all of the localities (including locality 4) which are known to have equilibrated to the 1,060 Myr age, and (2) only the two apparent age groups (~1,540 Myr and ~1,060 Myr) were revealed by the within-outcrop sampling[4], we interpret the present positions of the regionally-collected samples as meaning that each was collected from a subvolume which suffered disturbance or resetting during the ~1,060 Myr superimposed event. If each of these isotopic systems was completely rehomogenised, the sub-volumes would actually describe a number of parallel sub-isochrons corresponding to the ~1,060 Myr event, as occurs at locality 4. Moreover, if it is assumed that each sub-volume would most likely be characterised by a limited range in $^{87}Rb/^{86}Sr$ such as occurs at locality 4 and elsewhere[4], any sample taken from any locality would plot approximately along the 1,264 Myr, but geologically meaningless, apparent isochron. The model is schematically illustrated in the inset to Fig. 1. From this, it is evident that certain combinations of regionally collected samples would probably give rise to significant scatter, in which case it could at least be deduced that there had been some isotopic disturbance. More importantly, the data presented here show that regional sampling in this type of geological situation can also produce a combination which yields a good-fit intermediate apparent isochron (here, 1,264 ± 25 Myr). Despite a lack of significant scatter this isochron does not record a real isotopic event and is, therefore, geologically meaningless.

The model we have suggested is similar to a strontium isotopic equilibration model suggested by Roddick and Compston[8], with the important difference that, in the present case, there must have been systematic changes in $^{87}Rb/^{86}Sr$ and/or $^{87}Sr/^{86}Sr$ at each locality in order to displace all of the samples below the original 1,536 Myr isochron. The sub-volumes cannot have remained closed with respect to the Rb–Sr isotopes during the 1,060 Myr event. We have argued elsewhere that the main factor was net loss of ^{87}Sr, rather than increases in the Rb/Sr ratios[4].

In the example we have described, the $^{87}Sr/^{86}Sr$ initial ratio of the meaningless isochron (0.71107 ± 0.00194) is significantly higher than that given by the rocks which define the primary event (0.70345 ± 0.00014)[4], but other evidence suggests that this is not always so and that significantly lower $^{87}Sr/^{86}Sr$ initial ratios may also be generated (data not shown).

So far, we have related the problem of geologically meaningless total rock isochrons only to regionally collected samples, but the same situation might well arise within single outcrops if there is locally a wide dispersion in the $^{87}Rb/^{86}Sr$ ratios and isotopic resetting was only achieved within smaller sub-volumes. In such cases, the only sure way to test the scale of homogenisation during resetting would be to undertake isotopic analysis of minerals and of several total rock samples from each of a number of sub-volumes within the outcrop.

Our final conclusion is the same as that recently deduced by Bell and Blenkinsop[2]: selection of samples for isochron-age analysis should not be made solely on the basis of seeking the maximum possible spread in the $^{87}Rb/^{86}Sr$ ratios.

Visual lateralisation effect in reading Chinese characters

Ovid J. L. Tzeng, Daisy L. Hung & Bill Cotton

William S-Y. Wang
University of California, Berkeley, California 94720

Visual half-field experiments have been used to investigate perceptual differences in reading different types of writing scripts. It has been observed that tachistoscopic recognition of phonetic-based scripts (such as the English alphabet and Japanese Kana) tends to show a right visual field–left hemisphere (RVF-LH) superiority effect[1,2] whereas recognition of logographic symbols (for example, Chinese characters) tends to show a left visual field–right hemisphere (LVF-RH) superiority effect[3,4]. A cerebral orthography-specific localisation hypothesis has been proposed to account for these data. We have conducted three experiments to examine the visual lateralisation effect in reading logographic symbols such as Chinese characters. Chinese subjects in the first experiment were exposed to brief tachistoscopic presentation of a single character, and their task was to name the character as soon as possible. A LVF-RH superiority was found. In the second experiment, the stimuli were two vertically arranged characters and the subjects were asked to name the stimulus terms as soon as possible. The third experiment was the same as the second except that the task was to decide whether these character-strings were correct semantic terms with a manual response. A RVF-LH superiority effect was found in both the second and third experiments. These differential visual lateralisation results were interpreted as reflecting the function-specific property of the two hemispheres and cast doubt on the orthography-specific localisation hypothesis proposed by earlier investigators.

There has been much confusion in the literature as to whether asymmetries of function in the two sides of the brain arise from stimulus properties or from the nature of task requirements. Results of some recent clinical and experimental studies on the recognition of Japanese words have generally been used as evidence to support the former view. Among the many writing systems in the world today, Japanese is unique in that three types of script are used simultaneously to represent text. Most words in Japanese are written in Kanji, a logographic script, while grammatical particles are usually written in hiragana, and loan words (that is foreign words such as television) in katakana. The latter two are called Kana scripts and each symbol represents a syllable of the spoken language. So, a fluent reader of Japanese has to know all three types of script. Sasanuma and her associates[5] have presented evidence that the ability of Japanese aphasic patients to use the Kanji and Kana scripts may be selectively related to type of aphasic disorder. Moreover, such differential properties can also be demonstrated in visual half-field experiments on normal subjects, with a LVF-RH superiority for the recognition of Kanji characters and a RVF-LH superiority for the Kana symbols. The latter result is similar to those obtained with alphabetic writings. This implies that the underlying reason for this difference is the requirement of visual-to-sound mapping. Although there is indeed evidence for the left hemisphere specialisation for speech sound[6], generalisation of such findings to explain the differences between reading logographic symbols and reading alphabetic/syllabary symbols may be misleading. There is much evidence that reading logographic symbols also requires speech recoding[7]. Thus, what the hemispheric difference found in the tachistoscopic recognition of Kanji and Kana (or alphabetic) symbols reflects is not an

Table 1 Mean numbers of correct identification as a function of type of characters and of visual field

	Pictograms	Phonograms
Right visual field	5.20	5.60
Left visual field	13.30	14.20

The term 'lateralisation' refers to the specialisation of the left or right hemisphere of the brain for different functions. The rationale behind the visual hemi-field experiment is as follows. When a subject looks at a fixation point in the centre of a lighted square within a tachistoscope, each visual hemi-field projects to the contralateral hemisphere. So, for example, stimuli presented to the RVF are first processed in the left hemisphere. If language is indeed processed in the left hemisphere, then verbal stimuli presented to the RVF should take less time to respond than when the same materials are presented to the LVF. The delay in reaction time is attributed to the time it takes to transfer information from one hemisphere to the other. Or the experimenter can shorten the exposure duration so that the subjects are expected to make identification errors. Depending on the pattern of such an accuracy measure (that is RVF or LVF superiority) and on the materials used, specific functions of the left or right hemispheres can be inferred.

orthography-specific property; rather, it reflects a task-specific property of our cerebral hemispheric processing.

In our first experiment, 80 stimulus characters were selected from established norms of commonly used Chinese characters (both abstract and concrete terms were used). Two types of characters were selected: phonograms, which contain a phonetic component as a clue to the sound of the characters, and pictograms, which are pictographic in origin[8]. Figure 1 presents some examples of these two types of character. The subjects were 20 Chinese students (all right-handed) enrolled in the graduate school of the University of California, Riverside. The stimulus characters were presented one at a time either in the RVF or on the LVF by means of a three-channel tachistoscope. Each character was always preceded by an auditory signal plus a 500-ms fixation point presented in the centre of the screen. The duration of character presentation was adjusted for each subject according to his/her recognition threshold determined before the experimental session (range 20–75 ms; mean 40 ms). The subject was asked to identify verbally the stimulus character as soon as it was presented. The entire experiment forms a 2 (phonogram compared with pictogram) × 2 (RVF compared with LVF) design with both factors as repeated measures, and the dependent measure was the number of correct identifications. The results are summarised in Table 1. A 2 × 2 analysis of variance (ANOVA) was performed on the data. Only one main effect of the visual field is statistically significant, $F(1, 19) = 49.56$, $P < 0.001$. Apparently a strong LVF-RH superiority effect was obtained regardless of whether the characters contained any phonetic cue.

Although the result of a RH processing is clearcut, its implication for reading is less clear. Modern Chinese tends to be multiple-syllable, and so the perceptual unit in reading may be much larger than the single characters. Thus, a major task in reading is to generate meaning by putting together several characters to form meaningful terms. The second experiment, therefore, was conducted to investigate whether the results obtained in the previous experiment would be generalised to the tachistoscopic recognition of multiple-character terms. The procedure was the same as for the first experiment except that the stimulus terms were always two characters arranged vertically in either LVF or RVF of the tachistoscope. The results showed that of the 80 stimulus terms presented (40 for each field) the numbers of correct identification were 36.5 and 22.5 for stimulus terms presented in the RVF and LVF, respectively. The difference is statistically significant, $t(19) = 7.49$, $P < 0.001$. This result suggested a LH dominance, a complete reversal of the previous experiment. Therefore, the locus of the cerebral lateralisation cannot be on the logographic symbols *per se*; rather, it must be on the type of task a subject has to perform to meet the experimental requirement.

One may still object to the result of the second experiment on the basis that a LVF-RH effect as observed in the first experiment might be overridden by the LH function (it is conceivable that more effort is required to pronounce two characters) of motor programming in the oral report. To circumvent this objection, a third experiment was run to investigate the visual lateralisation effect with the subject making a semantic decision on multiple-character terms. Twenty Chinese graduate students were asked to make a 'yes/no' response as quickly and as accurately as possible to stimulus terms briefly exposed in either the RVF or LVF of the tachistoscope. They were asked to press the 'yes' key only if the characters formed a meaningful term, otherwise to press the 'no' key. The right-hand or left-hand responding to the 'yes' or 'no' key was counterbalanced across subjects. We also manipulated the imagery value by dividing the stimulus terms into 16 high and 16 low imagery terms. Thirty-two meaningless character strings were constructed to balance the positive and negative instances. The dependent measure was the reaction time (RT) required to make a correct decision. The results are summarised in Table 2.

First, subjects took much longer to make a negative response than a positive response and the data on negative responses were much noisier than those on the positive responses. Because our interest is in the positive reponse in various experimental conditions, ANOVA for a 2 (RVF compared with LVF) × 2 (high compared with low imagery) factorial design with both factors as repeated measures was performed on RTs of the correct positive responses. The main effect of imagery is significant with the high imagery terms having a 62-ms advantage over the low imagery terms, $F(1, 19) = 5.69$, $P < 0.05$. This is consistent with previous findings[9]. The main effect of visual field is also highly significant, $F(1, 19) = 14.52$, $P < 0.002$, with RVF performance having a 104.1-ms advantage over the LVF performance. In other words,

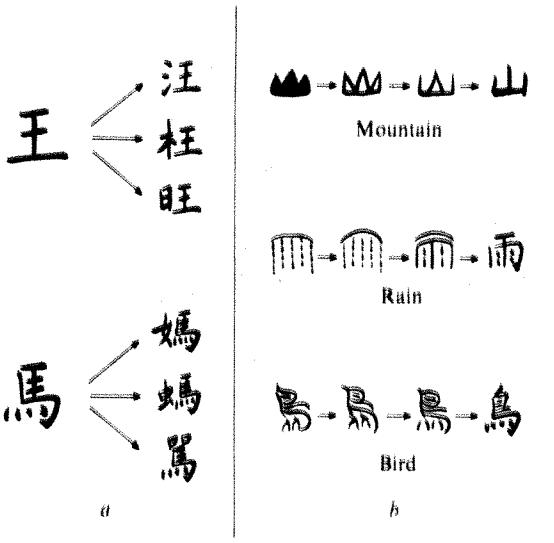

Fig. 1 *a*, Examples of Chinese phonograms. In the upper panel, the character on the left hand side is the base character and is pronounced as 'wáng' (meaning 'king'). The three characters on the right are derivatives which contain the base character as a clue to their pronunciation. In fact, they are pronounced as 'wāng', 'wǎng' and 'wàng' from top to bottom, meaning 'the barking sound of dogs' (or alternatively, 'deep and wide'), 'not straight', and 'prosperity' for the three characters, respectively. In the lower panel, the base character on the left is pronounced as 'mǎ'. It means 'horse' and it is a pictogram by itself[8]. Similarly, the three derivative characters on the right are pronounced as 'mā', 'má' and 'mà', meaning 'mother', 'ant' and 'to scold', respectively. Thus, if a reader knows how to pronounce the base characters, he can guess the pronunciation of the derived phonograms which contain the base character as its partial component. However, one should be cautious in making generalisations because in a lot of cases the base character only gives a clue to how a particular phonogram sounds (sometimes the clue refers only to the vowel ending) and the tonal patterns (—, ⁄, ∨, ∖) are not included. *b*, Examples of the pictograms and their transformation through hundreds of years.

Table 2 Mean reaction times for correct decision as a function of imagery value and of visual field

	Positive response		
	High imagery	Low imagery	Negative response

Left visual field	906.34	993.52	1,391.32

Responses are given in ms.

the results showed a RVF-LH superiority effect, replicating the result found in the second experiment.

Superficially, this result of a LH dominance seems to be in conflict with those of the first experiment. However, these data are compatible with the current view of cerebral organisation which maintains that, for most right-handed people, the left hemisphere is better at handling sequential and analytical tasks while the right hemisphere is better at handling holistic pattern recognition tasks[10]. Because the experimental task in the first experiment emphasises a holistic recognition of the single characters and because the experimental task in the second and third experiments emphasises putting character strings together to get at the lexemes of the terms, the results of these three experiments not only do not conflict with one another, but rather they support the differential-function views of cerebral organisation. Table 2 shows that the data on the imagery variable are consistent with this interpretation.

According to this view, the right hemisphere is superior in perceiving overall form. Clearly, the LVF-RH advantage for single-character recognition must have derived from this source, although final pronunciation of the meaning of the character must be mediated by the left hemisphere. This implies that the left hemisphere's articulatory superiority is outweighed by the right hemisphere's form-perception superiority for the single-character test. It seems evident that the reading and interpretation of Chinese characters calls on the specialised functions of both sides of the brain, and that whether one or the other side manifests superiority in a particular task depends on the balance of cognitive requirement.

Spider feeding behaviour optimises dietary essential amino acid composition

Matthew H. Greenstone*

Department of Zoology, University of California, Berkeley, California 94720

Classical models of foraging behaviour[1–3] assume that feeding patterns maximising the net caloric gain per unit time or minimising the time spent in foraging will be favoured by natural selection. There is some evidence for this behaviour in some foragers[4], mostly higher vertebrates for which time and energy constraints are frequently paramount. However, while these models may suffice under some circumstances, nutritional information from the veterinary, wildlife management, and entomological literature shows that an animal requires a diet containing all necessary nutrients to be truly fit (physiologically and evolutionarily). Therefore unless animals are very severely constrained energetically, foraging behaviour should lead to nutritional as well as caloric optimisation. Here I show that free-living wolf spiders will tend to prey on three species in proportions which optimise the proportions of the essential amino acids they provide in the diet.

The small (<50 mg) lycosid, *Pardosa ramulosa* (McCook), is associated in California with standing water, where it feeds predominantly on aquatic insects[5]. In the Petaluma Marsh in Sonoma County the spiders are found at isolated brackish pools. Eighty per cent of their diet comprises three insect species, the shore fly, *Ephydra riparia*, the waterboatman, *Trichocorixa reticulata*, and the mosquito, *Aedes dorsalis*[5].

Information on short-term dietary selectivity in the presence of a particular set of prey availabilities was obtained by statistical analysis of qualitative data on spider stomach contents, which were identified with a passive haemagglutination inhibition assay[6]. Because the assay has perfect specificity, each spider may be unambiguously scored either positive or negative for the presence of each of the three insect species. On this basis, each spider in a sample may be assigned to one of the eight cells of a $2 \times 2 \times 2$ contingency table for a test of independence among the prey species in the diet, using the marginal totals to compute the expected numbers of spiders in each cell. The null hypothesis

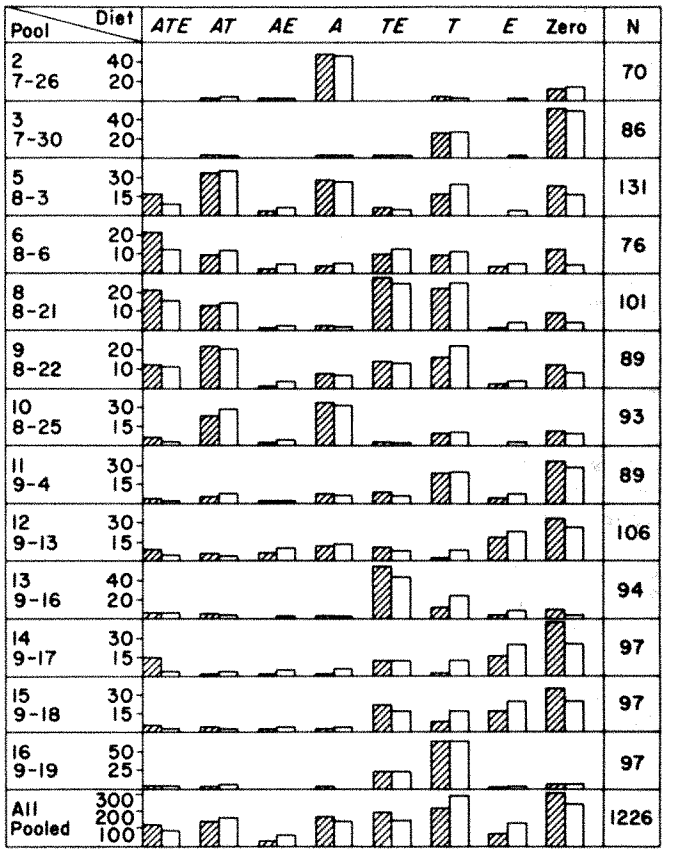

Fig. 1 Observed (hatched bars) and expected (open bars) numbers of spiders with each of the eight possible kinds of diets. Symbols are as in Table 1. A certain proportion of the spiders in the contingency table (the 'zero' category) are expected to be negative for all three species. In addition to these animals, a subset of the sample, whose identities are unknown, will not be feeding because they are preparing to moult[13]. Three per cent of the spiders in a laboratory population were not eating at any given time because of preparation for moult (unpublished data). Therefore, 3% of each sample, as zeroes, were omitted from the analysis in order to avoid an artificial inflation of the observed number of zeroes in the contingency table.

can be rejected in either of two ways. Positive association is consistent with a hypothesis of nutrient optimisation in which certain proportions of several species provide more nearly optimal proportions of nutrients than does any single species, or in which taking a variety of species minimises the consumption of specific noxious defensive compounds from each one[7]. Negative association of prey species in the diet would suggest specialisation on a particular species, because it provides the greatest net caloric gain or a more nearly optimal nutrient balance than any combination of species. It must be emphasised that the availabilities and dispersions of prey species on any given date and any prey species differences in catchability, visibility, and encounter rate are completely irrelevant to this analysis since they are subsumed in the marginal totals of the contingency tables.

Thirteen samples of about a hundred spiders each were collected during the summer of 1974, and the observed and expected values for the contingency tables derived from the immunological analysis of their stomach contents were compared by means of the *G* test[8] (Table 1). The pooled data, and nine of the thirteen individual samples, show significant departure from independence; in the majority of samples this is due entirely to *Trichocorixa* × *Ephydra* heterogeneity. The observed and expected values for the eight cells of each table are shown in Figure 1. All of the significant pools show an excess of triple positives and, with the single exception of pool 6, an excess of spiders positive for *Trichocorixa* and *Ephydra* and negative for *Aedes*, and deficiences of *Trichococrixa* and *Ephydra* singles. These data indicate dietary mixing.

Because of the importance of essential amino acids in the diets of arthropods[9,10], I decided to test the hypothesis that the significant positive associations of prey species reflect attempts by the spiders to provide the most nearly optimal proportions of essential amino acids in the diet. The null hypothesis is that the proportions of amino acids in the diets of the average spiders in the four nonsignificant samples (pools 2, 3, 10 and 16) are not significantly more or less similar to the optimal proportions than are the proportions of amino acids in the diets of average spiders in the nine significant samples. The test hypothesis is that the proportions of essential amino acids in the diets of the average spiders of the nine significant samples are significantly more similar to the optimal proportions than are the proportions of essential amino acids in the diets of the average spiders of the four non-significant samples.

Spider extracts were prepared by grinding whole animals in distilled water. Haemolymph alone was used for the insect comparisons (see ref. 6 for method of extraction) because the spiders do not consume their prey intact and therefore do not ingest skeletal material.

The optimal proportions of essential amino acids are assumed to be those in the spiders themselves. (This is obviously a first approximation since rates of utilisation may not be the same for all amino acids.) The proportion of the *i*th amino acid in the diet of the average spider in a sample is given by

$$p_i = \frac{\Sigma_j \lambda_j \mu_{ij}}{\Sigma_i \Sigma_j \lambda_j \mu_{ij}} \quad (1)$$

where λ_j is the mean number of individuals of prey species j per spider stomach in the sample and μ_{ij} is the weight of amino acid i in an individual of prey species j. The proportions of the 10 essential amino acids in the spiders and their prey (Table 2) were determined by dansylation and chromatography[11] of appropriate extracts. The λ_j values were estimated from the immunological data by assuming that the number of individuals of each prey species per spider stomach is a Poisson variate[12]. Then the probability that a stomach contains r items of species j is given by

$$p_{rj} = \frac{\lambda_j^r e^{-\lambda j}}{r!}$$

from which it follows that

$$\lambda_j = -\ln (p_{0j})$$

where p_{0j} is the proportion of spiders in the sample which is negative for species j, after correction for animals not feeding because of preparation for moult[13]. The resulting λ_j values were corrected for differences in the length of time during which individuals of the three species remain detectable in the stomach[5,14]. These corrected λ_j values (Table 3) were entered into equation (1) to compute the proportion of each of the ten essential amino acids in the diet of the average spider in each sample.

The similarity between each of the 13 average diets and the optimum diet was indexed using vector dot products. Since the proportions in any diet or in the optimum sum to 1.0, the sets of proportions can be represented as probability vectors. The dot

product of two vectors, α and β, is[15]

$$\alpha \cdot \beta = |\alpha||\beta| \cos \theta$$

In the case of probability vectors,

$$\theta = \text{arc cos} \frac{(\Sigma p_{di} p_{oi})}{(\Sigma p_{di}^2 \Sigma p_{oi}^2)^{1/2}} \quad (2)$$

where p_{di} is the proportion of the ith amino acid in the diet which is being compared to the optimum and p_{oi} is the proportion of the ith amino acid in the optimum diet. When two vectors are identical $\theta = 0°$. The more dissimilar they are the larger θ becomes, up to a maximum of 90° (ref. 16).

The θ values computed for each pool's average diet versus the optimum using equation (2) are presented in Table 3. There is no overlap between the θ values of the two sets of comparisons, all of the non-significant pools' diets' comparisons showing θ values between 19.24° and 21.92°, and all of the significant pools' diets' comparisons showing θ values between 13.11° and 18.18°, indicating diets with a closer similarity to the optimum. This difference is highly significant by the Mann–Whitney U-test[17], ($U = 0$, $n_1 = 4$, $n_2 = 9$, $P < 0.001$), and strongly supports the nutritional hypothesis.

Dietary mixing has been reported in rats[18], deer mice[19], and flour beetles[20] in the laboratory, and in songbirds in the field[21], but has not yet been described in free-living invertebrate predators. The fact that a bug (*Trichocorixa*) and a fly (*Ephydra*) were most often associated in the spiders' diet agrees with field observations that the insects most heavily represented in the diets of European[22,23] and North American[5,24] *Pardosa* species belong to the orders Homoptera, Hemiptera and Diptera. Perhaps these spiders have adopted this particular form of polyphagy for nutritional reasons. Such behaviour probably has selective value, since, in the laboratory at least, survival[25,26] and fecundity[26] are higher in *Pardosa* species raised on multiple species than on single species diets.

Recognition of the importance of nutrients besides calories has appeared in the optimal foraging literature in the past few years[27–32]. It has been suggested, for example, that protein nitrogen[27,28] or other nutrients[29] be substituted for calories as the currency for optimisation. In reality the decisions made by foraging animals will probably be better represented by more complex models entailing compromises in the simultaneous optimisation of caloric and other nutritional factors and, as shown in the present study, concerned with both the quality and quantity of nutrients.

I thank Robert Colwell for useful discussions, Irene Baker for performing amino acid analyses, Steve Selvin, Robert Sokal and Howard Tucker for statistical advice and Paul Summarco for performing G-tests. I also thank Charles Mitter and Robert Sokal for helpful comments. This work was supported in part by NSF grant GB 41178 and a Biomedical Research Support grant from the School of Biological Sciences, University of California, Irvine.

Chronic intracerebroventricular infusion of insulin reduces food intake and body weight of baboons

Stephen C. Woods, Elizabeth C. Lotter, L. David McKay & Daniel Porte Jr

Departments of Psychology and of Medicine and the Regional Primate Center, University of Washington, and the Seattle Veterans Administration Hospital, Seattle, Washington 98195

Body adiposity is normally maintained within rigid limits[1–3]. Although it is not clear that this regulation fits a strict negative feedback pattern, animals do maintain a relatively constant body adiposity[4]. It has been postulated that this regulation is mediated by some signal which informs centres controlling food intake, probably located in the brain, as to the present state of adiposity[5,6]. The identity of the signal is unknown, but the direct correlation between body adiposity and basal insulin levels in the plasma[7–9], suggests insulin as a possible candidate. This hormone is present in the cerebrospinal fluid (CSF) of many species[10–13], and is a slow integral over time of the level within the plasma[14]. Thus, the level of insulin in the CSF is relatively resistant to short-term plasma fluctuations of insulin. Obese humans have higher levels of CSF insulin than lean controls and the CSF insulin level of both obese and lean humans is reduced proportionately after a prolonged fast[15]. We have therefore postulated[16] that the feedback system responding to body adiposity uses the concentration of insulin in the CSF as a major signal. Additional support for such a role is found in recent reports that insulin receptors are present in several regions of the brain and spinal cord[17–20]. We now present additional evidence for our hypothesis by showing that in baboons the infusion of exogenous insulin into the CSF elicits a reliable and predictable decrease in food intake and body weight.

To test this hypothesis we have developed a baboon model in which chronic feeding can be monitored in unanaesthetised animals and in which experimental access to the blood and CSF is maintained. Animals were maintained in standard primate restraining chairs for 3–6-week studies during which solutions of sterile buffered salt solution, 'synthetic CSF' (ref. 21), were infused into the animals' lateral cerebral ventricles with or without insulin or glucagon. To do this, an acrylic pod with six cannula guide sleeves was stereotaxically fixed to the skull while the animal was anaesthetised with halothane[22]. The guide sleeves were cut so that their tips would lie at the dorsal surface of the lateral cerebral ventricle, and X rays were used to compare their positions with the plates in Riche[23].

All animals were adapted to a commercially available liquid diet (Ensure, Ross, containing per l approximately 37 g fat, 37 g protein and 145 g carbohydrate with additional vitamins and minerals) which was freely available in stainless steel drinking cans placed on the chairs from 8.30 a.m. to 3.30 p.m. each day. Water only was available from 3.30 p.m. to 8.30 a.m. Food intake was determined by periodic volumetric determinations of remaining diet during the feeding interval, with addition of supplemental diet as appropriate.

To verify that infusions through the cannula actually reached the CSF, we routinely injected each animal with 5 μg of angiotensin II through a cannula 1–2 mm longer than the guide sleeve and determined subsequent water intake. An increase in water intake of more than 50 ml over the 30 m following the injection relative to the water intake on a control day was taken as indicative that the cannula had access to the CSF. The mean water intake over the 30-m interval immediately following the injection of the angiotensin II was 277 ml greater than that on a control day when only the vehicle was injected.

The intraventricular cannulas were infused at a constant rate between 1 and 1.5 ml per day. Infusions of synthetic CSF had no apparent effect on food intake, body weight, basal plasma insulin or glucose levels for prolonged intervals (see Table 1 and Fig. 1). After a control or baseline interval, insulin (bovine/porcine insulin, Lilly) was added to the infusate at doses of 1, 10 or 100 μU per kg per day. A given baboon received each dose of insulin only once, and the order of the various conditions was random. The lowest dose of insulin was chosen because we reasoned that if this was given in a single dose instead of being infused over a 24-h period it would approximately double the concentration of insulin in the CSF. This assumed that the level of insulin within the CSF of the baboon is approximately 25% of the level in the plasma, as it is in other species[10–14], and that an average baboon weighs 15 kg and has a ventricular volume around 1 ml. The increment of CSF insulin achieved with the lowest infusion dose was probably negligible as it was actually infused over a 24-h interval and the half life of insulin in the CSF of the dog is around about 1.5 h (ref. 12).

Results of this procedure are summarised in Table 1, which contains the mean values for a 2-week baseline interval in which only synthetic CSF was infused and analogous mean values for the intervals after with the infusion of insulin or glucagon (Lilly). Figure 1 depicts the daily food intake for these conditions. Although there was considerable daily variation in food intake, there was a significant, dose-related decrease in food intake when insulin was added to the infusate. The data were analysed using non-parametric statistics because there was often heterogeneity of variance between conditions and because not every baboon was used in every condition. For the analyses, a mean value was obtained for each animal over the 14-day baseline period. A second overall mean value was obtained for the interval when the hormone was actually infused. These data were then analysed using an overall Kruskal–Wallis test with individual conditions compared by the Mann–Whitney test[24]; $P < 0.05$ indicated significance. It should be clear that the analysis was very conservative, as the use of some other parameter (for example, a mean of the last 5 days' values in each condition) would have resulted in a larger change, thus giving a greater probability to achieve a significant effect.

There were no reliable differences between baseline parameters for the four conditions (three insulin doses and one glucagon dose). For food intake (Table 1) there was a significant reduction during infusion of both the two larger doses of insulin, and the intake during the largest dose (100 μU per kg per day) was significantly less than that during the intermediate dose

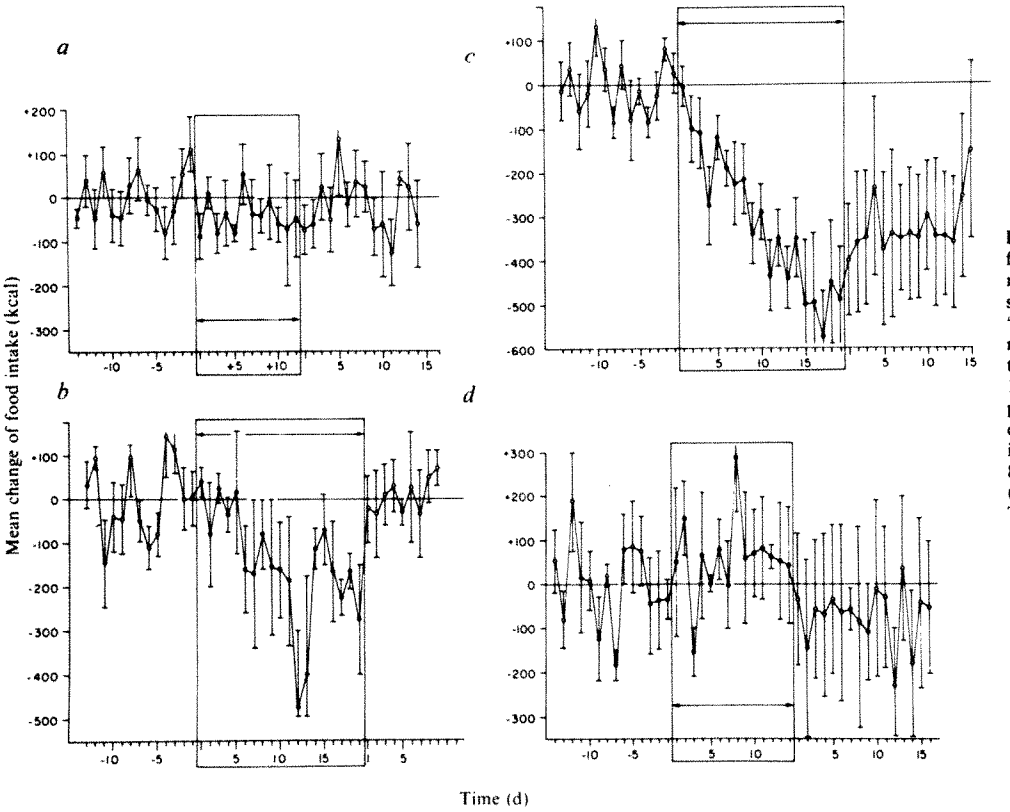

Fig. 1 Daily food intake values for the four experiments. Points and bars represent the mean ±1 s.e.m. Open symbols represent control intervals when 'synthetic CSF' was infused; solid symbols represent intervals when insulin at one of three doses (*a*, 1 μU per kg per day; *b*, 10 μU per kg per day; *c*, 100 μU per kg per day) or glucagon (*d*, 2.35 ng per kg per day) was infused. In *a* the mean baseline intake was 821 kcal d^{-1} ($n = 5$), in *b* 860 kcal d^{-1} ($n = 4$), in *c* 781 kcal d^{-1} ($n = 6$) and in *d* 726 kcal d^{-1} ($n = 3$). Times of hormone infusions are boxed.

Table 1 Food intake, plasma insulin, plasma glucose and body weight for the baseline and hormone-infusion portions of the experiment

	Mean food intake (kcal)*	Mean plasma insulin (μU ml^{-1})*	Mean plasma glucose (mg ml^{-1})*	Mean body weight (kg)*	Final body weight (kg)†
Baseline	821±121	71.5±11.1	86.3±1.9	17.8±2.6

* These values represent an average (mean±s.e.m.) for the entire infusion interval.
† These values are those of the final day of hormone infusion and are indicative of the total weight change achieved.
‡ Significantly different than the analogous value during the lowest dose of insulin.
§ Significantly different than the analogous value during the intermediate dose of insulin.
‖ Significantly different than the analogous value during the highest dose of insulin.

(10 μU per kg per day). The food intake during the glucagon infusion did not differ significantly from that during the baseline period, nor from that during the infusion of the smallest dose of insulin. It was significantly greater than the intake during the infusion of the largest dose of insulin. With respect to body weight, only the largest infusion of insulin resulted in a significant decrease relative to the baseline or to the smallest dose. The body weight during the glucagon infusion was not consistently different from that during the baseline but significantly larger than that obtained during the infusion of the largest dose of insulin. There were no differences in plasma insulin (as determined by immunoassay)[25] or plasma glucose (as determined by the glucose oxidase method) during any hormone infusion interval relative to control. There was a significant dose-related reduction in body weight, but no reliable change in plasma insulin or glucose during these intervals (Table 1), suggesting that leakage of infused insulin from the CSF to the blood was minimal.

The weight losses at the end of the sessions during which the two larger insulin doses were infused (see last column in Table 1) were approximately what one would expect based on the decrease in food intake. If one assumes that 1 g of stored fat yields about 7 kcal (ref. 1), the mean daily decrease of 158 kcal for 19 days (based on the figures for the 10 μU per kg per day dose) would be expected to cause a mean decrease of 429 g of body weight. The actual decrease was 374 g. Similarly, the expected decrease in weight in animals given the largest insulin dose for 19 days would be 866 g, whereas the actual weight loss was 812 g.

At the end of an experimental infusion session in which food intake was depressed, food intake rapidly returned towards the baseline control level. However, the rebound was not complete following the infusion of the largest dose of insulin even after 2 weeks (see Fig. 1).

Glucagon was infused as a peptide control at the same molar dose as the highest effective dose of insulin. As shown in Table 1 and Fig. 1, glucagon infusion at this dose had no consistent effect on food intake, body weight, plasma insulin or plasma glucose. If anything, there was a slight tendency for the baboons to increase their food intake. This was most apparent as a rebound decrease in food intake after the end of the glucagon infusion (Fig. 1), although this result was not statistically significant. However, it is clear that the suppression of food intake observed when equimolar amounts of insulin were infused did not occur with glucagon. This control therefore makes some nonspecific illness-related explanation unlikely, especially when one considers that glucagon, when given peripherally, reportedly makes animals ill and causes them to eat less[26,27].

We have interpreted these results to support the theory[16] that CSF insulin levels may serve as a signal to inform the brain of the present state of adiposity. It may well be that other, analogous systems exist in which CSF-borne peptides influence behaviour. For body weight regulation, the observed system closes the feedback loop between the brain and the endocrine pancreas[28,29]. Independently of the theoretical interpretation, there are potential practical implications of these findings. We have found that we can reduce the food intake and body weight of baboons by altering the amount of a hormone already present in the CSF. It will be important to determine if this system is operative in man and if there are possible therapeutic implications for human obesity.

Nerve sheaths and motoneurone collateral sprouting

J. R. Slack*, W. G. Hopkins & M. N. Williams

Department of Physiology, School of Medicine, University of Auckland, Private Bag, Auckland, New Zealand

When disease or injury causes partial loss of innervation from a muscle, the remaining axons sprout and form new connections to the denervated muscle fibres[1]. Sprouting can occur in two ways: from axon terminals (terminal sprouting) or from the intramuscular axons themselves, probably from the nodes of Ranvier (collateral sprouting)[1,2]. Terminal sprouting has been induced experimentally using various methods, including partial denervation[2], nerve conduction block[3] and nerve transmission block[4,5]. A common factor in the induction of terminal sprouting seems to be changes in the surface membrane of muscle fibres[6,7]; these changes and terminal sprouting are prevented by direct stimulation of the muscle[5]. Collateral sprouting has been induced only by partial denervation and is not prevented by direct stimulation[5]. This has been taken as evidence[6] for an earlier suggestion[2] that products of nerve or axon degeneration may be a direct stimulus for collateral sprouting. We report here that axon degeneration products alone are probably not the stimulus for collateral sprouting.

Collateral sprouting in response to partial denervation was examined in a mouse hind limb muscle, tensor fascia latae (TFL), which is normally innervated by 11 axons from lumbar spinal nerves L4 and L5. Mice (15–20 g body weight) were anaesthetised intraperitoneally with chloral hydrate (0.1 ml of 5% solution per 10 g body weight), and partial denervation of TFL was achieved by cutting and redirecting the proximal stump of L4 into the peritoneal cavity. This operation results in the degeneration of a variable number of TFL axons, but usually nine. Muscles were exercised up to 30 days after the operation, stained by the combined silver and cholinesterase method of Namba *et al.*[8], mounted whole between two coverslips and examined in the light microscope under a ×100 oil immersion objective. By this method endplates, axons, axon sprouts and perineurial sheaths were visualised throughout the entire muscle. The lengths of sheaths, axons and sprouts were measured using a calibrated 10×10 square graticule in the microscope eyepiece. Sprouts are clearly distinguishable from the pre-existing terminal axons by two criteria. First, the diameter of sprouts and pre-existing axons are significantly different (0.47 ± 0.10 μm, $n = 38$ and 1.79 ± 0.39 μm, $n = 95$, mean ± s.d., respectively). Second, sprouts have uniformly smooth profiles while pre-existing terminal axons possess characteristically gnarled profiles (Fig. 1).

The nerve of TFL branches within the muscle to form smaller bundles of axons (intramuscular nerves) and finally single terminal axons which contact individual muscle fibres. There are no sprouts in muscles removed 1 day after partial denervation. Extensive axonal degeneration is visible within the perineurial sheaths of the intramuscular nerves, some of which contain surviving intact axons. Denervated terminal axon sheaths arise from intramuscular nerve branches and terminate on cholinesterase-stained endplates. Muscles removed from animals two or more days after partial denervation show fine collateral sprouts, which reach denervated muscle fibres by growing down denervated sheaths. Not all the sprouts observed reached cholinesterase-stained endplates. Some (21%, $n = 190$) end in bulbous enlargements similar in appearance to growth cones described by Ramon Y Cajal[9] in silver-impregnated developing axons. These sprouts which end within perineurial sheaths are most common in muscles partially denervated between two and five days before excision.

Sprouts arise from intact axons close to points at which denervated sheaths branch from partially denervated intramuscular nerves (Fig. 2). In four muscles partially denervated for less than 9 days sprout sites are ~22 μm from the branch points (22.4 ± 1.8 μm, $n = 77$). In two muscles partly denervated for 16 and 30 days, sprouts arise ~38 μm from the branch points (38.1 ± 43.9 μm, $n = 62$). Sprouts are absent from quite long segments of intramuscular nerve (400–600 μm). If axon degeneration products were the sprouting stimulus, sprouts would be expected throughout these segments, because they

* To whom correspondence should be addressed.

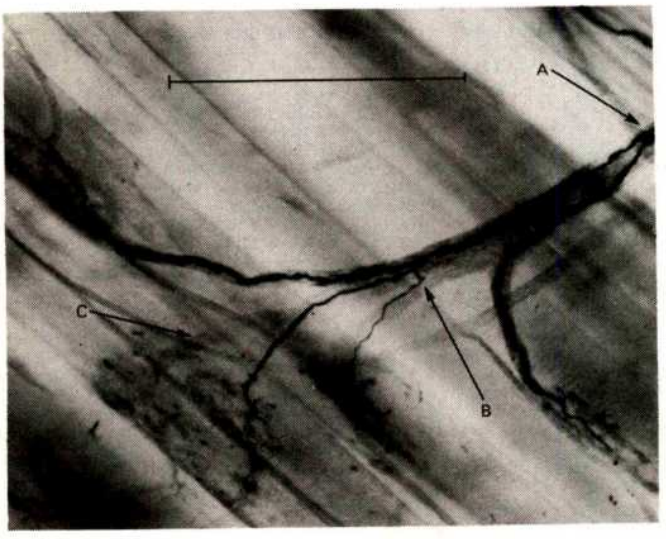

Fig. 1 Light micrograph of combined silver and cholinesterase-stained TFL muscle. The muscle was partially denervated 8 days before excision. Perineurial sheaths enclose two pre-existing terminal axons which arise at arrow A. Cholinesterase enzyme product is visible as speckled deposits over terminal arborisations. A fine collateral sprout arises at arrow B and follows a sheath to a nearby endplate. A denervated sheath (arrow C) arises near B. The axon branch between sprout B and denervated sheath C is one of a small number of profiles (9%, $n = 741$) with a diameter intermediate between that of sprout and pre-existing axon. It may be either a sprout in the process of maturation or an unusually thin pre-existing axon; these are excluded from all sprout statistics. Scale bar, 100 μm.

contain degenerating axons for several days following partial denervation. The degenerating axons are not separated from the intact axons by septa[10] or other diffusion barriers which might prevent access of degeneration products to intact axons (unpublished observations of electron micrographs). The absence of sprouts is not due simply to the absence of potential sprout sites, probably nodes of Ranvier, which occur frequently in these segments (internodal distance = 163 ± 61 μm, $n = 31$, from three muscles). Moreover, the sprout-free segments of nerve are

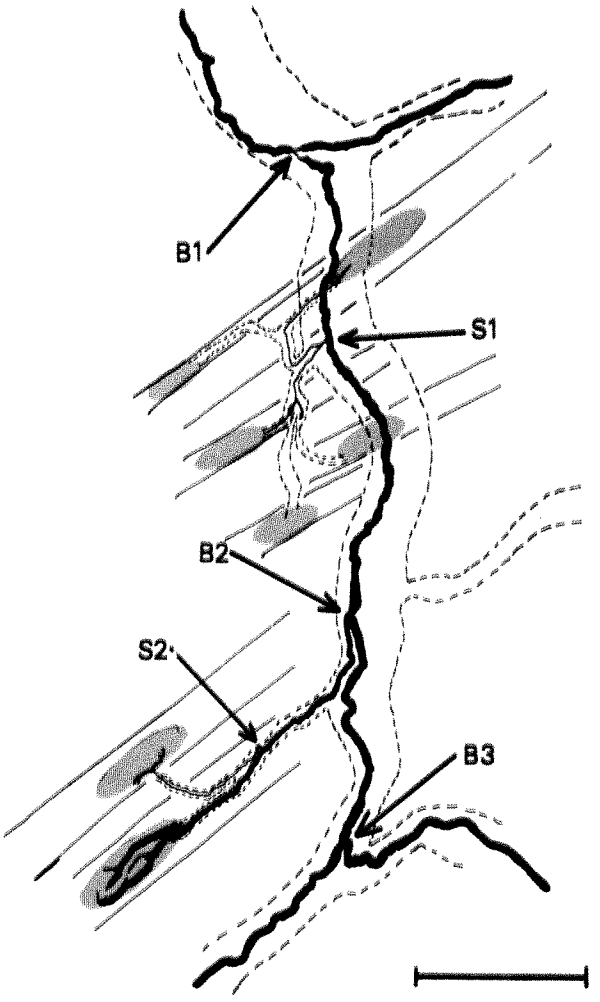

Fig. 2 Camera lucida tracing of a segment of intramuscular nerve from a TFL muscle excised and stained 4 days after partial denervation. Perineurial sheaths enclose degenerating axons (not drawn) and a single intact axon with branch points at B1, B2 and B3. Sprouts arise at S1 and S2 and innervate endplates (shaded areas). A terminal axon arising at B2 also innervates an endplate within the field shown. Note that there is no sprouting at the branch points. In other regions of this muscle, the nodes of Ranvier at branch points are also sprout sites. Scale bar, 100μm.

flanked by denervated sheaths containing sprouts, making it unlikely that these segments are for some reason refractory to a sprouting stimulus from degenerating axons.

Denervated terminal axon sheaths become sprout innervated in a sequential manner. We have measured the lengths of sprout-containing sheaths from the endplate to the point where the sprout arises in the intramuscular nerve. In some cases where the sprouts ended in a 'growth cone' short of the cholinesterase-stained endplate we measured the entire distance from the point of sprout outgrowth along the sheath to the endplate. We found that the shortest denervated sheaths are the first to become innervated by sprouts, as shown in Fig. 3.

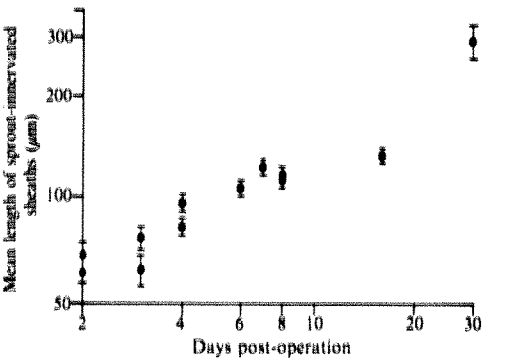

Fig. 3 Mean length of sprout-innervated sheaths plotted as a function of time after partial denervation. Each point represents one muscle and shows the mean ±s.e.m. for between 21 and 68 sheaths. Mean pre-existing terminal axon length for the 12 muscles in this figure is 130 ± 8 μm (mean ± s.d.).

These results do not seem to be compatible with a mechanism in which sprouts are initiated simply by the products of nerve or axon degeneration. At least two classes of mechanism for collateral sprout initiation are consistent with our findings. First, the sprouting stimulus might be a diffusable substance in the extracellular space which reaches intact axons either directly across denervated sheaths or via the terminal ends of denervated sheaths. Second, the stimulus might arise from changes in either the denervated Schwann or perineurial sheath cells developing first near the terminal ends of the sheaths, and subsequently spreading back towards the intramuscular nerves containing intact axons.

Teratogenic drugs inhibit tumour cell attachment to lectin-coated surfaces

Andrew G. Braun, David J. Emerson & Bradley B. Nichinson

Harvard Medical School, Department of Radiation Therapy, 50 Binney Street, Boston, Massachusetts 02115

Interactions between embryonic cells are generally thought to have a central role in the control of development[1]. When these morphogenic interactions are interrupted by either physical intervention[2] or genetic defects[3], normal development is impaired. In accord with these experiments, specific interactions between embryonic cells have been demonstrated in several *in vitro* systems. Many investigators have described homotypic aggregation of chick embryo cells[4–6], and heterotypic specificity has also been described[9]. Because of the importance of morphogenic cell–cell interactions in development it follows

0028–0836/79/480507–03$01.00

© 1979 Macmillan Journals Ltd

that agents that interfere with these interactions, regardless of the interference mechanism, are potential teratogens. Here we have used a simple *in vitro* cell to surface recognition system in an attempt to screen for potential teratogens. We have found a very high correlation between inhibitory activity in the *in vitro* assay and reported teratogenic activity in human or animal studies. This suggests that many teratogenic agents may act by interfering, in an as yet unknown way, in normal cell to cell interactions.

In this system, tumour cell attachment to concanavalin A-coated plastic surfaces, mediated by a cell-surface carbohydrate–concanavalin A receptor interaction, has been used to mimic some features of the complex interactions to be expected during development. Tumour cells are useful because of their availability in large, homogeneous quantities and ease of preparation. In addition, they have long been known to have properties in common with cells of embryonic origin[10]. Of particular relevance is the observation that although normal fibroblasts attach poorly to surfaces derivatised with lectins (ref. 11 and A.G.B., unpublished observations), transformed fibroblasts, tumour cells (refs 11–13 and A.G.B., unpublished observations) and some embryonic cells (P. Spear, J. L. Wang and G. M. Edelman, unpublished, but cited in ref. 25), attach to these surfaces. Both embryo cell aggregation and tumour cell attachment to lectin-coated surfaces require energy[6,11]. Thus, it is plausible that the attachment of tumour cells to lectin-coated surfaces can serve as a simple *in vitro* model for the morphogenic interactions observed *in vivo*.

Tumour cell attachment to lectin-coated surfaces was quantified by using 1.25-cm diameter polyethylene disks and ascitic mouse ovarian tumour (MOT)[14] labelled with tritiated thymidine *in vivo*. We have found that the tumour cells attach to lectin-derivatised disks rapidly, within 5 min at room temperature. To assay for the inhibitory activity of a drug, tumour cells (1 ml at 5×10^6 per ml) were incubated with the drug, usually for 30 min at 37 °C, poured into a 35-mm polycarbonate Petri dish and several disks submerged into the suspension. As dead cells do not attach to lectin-coated surfaces the drug concentrations used here were kept below overtly toxic levels as determined by trypan exclusion. After a 20 min incubation at room temperature the disks were removed with fine forceps, washed in saline and counted in a scintillation counter. An example of the inhibitory activity of several anaesthetics and tranquilisers is shown in Fig. 1. Similar concentrations of these drugs have been reported to inhibit lymphocyte capping in similar conditions[15]. Of the five drugs shown in Fig. 1, four are known to cause congenital malformations *in vivo*[16]. We have been unable to determine whether lidocaine is a teratogen.

Curves similar to those of Fig. 1 have been generated for 55 drugs with known teratogenic properties. To characterise the inhibitory activity of a drug we have found it useful to determine the ID_{50}—the dose of drug that inhibits 50% of tumour cell attachment. Table 1 lists these 55 drugs according to their inhibitory properties. Of drugs found to inhibit attachment, 31 of 33 (94%) have been reported to be teratogenic *in vivo*. Note the wide range of agents which inhibit attachment; these include

Table 1 Inhibition of tumour cell attachment to concanavalin A-derivatised polyethylene disks

Inhibitory drug				Non-inhibitory drug			
	ID_{50}	Teratogen	Ref.		Maximum concentration	Teratogen	Ref.
Aspirin	14 mM	+	16	Colchicine*	5 mM	+	16
Phenylbutazone	0.12 mM	+	17				
Procaine	11 mM	+	16	Chloroform	33.5 mM	−	18

Noradrenaline HCl	0.24 mM	+	16				

Drugs were tested for inhibition of attachment as described in the text and in Fig. 1 legend. In nearly all cases incubation with drugs was for 30 min at 37 °C. The assignment of *in vivo* teratogenic activity was based on the reference cited. +, Teratogenic *in vivo* according to cited ref.; −, non-teratogenic, according to cited ref. The maximum concentration tested was limited by solubility of the drug in phosphate-buffered saline or by its toxicity as judged by trypan blue exclusion.

* Drug dissolved in dimethyl sulphoxide (DMSO). The final concentration of DMSO did not exceed 0.3 M, a non-inhibitory concentration.

† Drug dissolved in ethanol. The final ethanol concentration was not inhibitory.

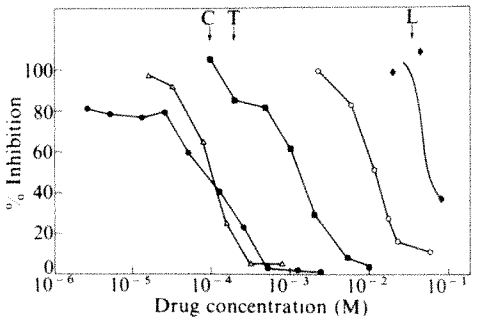

Fig. 1 Inhibition of MOT cell attachment to concanavalin A-derivatised disks. Disks were cut from 15-ml polyethylene with a 1.25 cm diameter die and derivatised in a solution of 0.1 mg ml^{-1} concanavalin A and 2.5% glutaraldehyde overnight. The disks were washed in buffer and stored in 0.3 M glycine. Just before use they were again washed in buffer. The surface density of concanavalin A receptors on disks prepared in this manner has been estimated by tritium-labelled glucose binding to be 3×10^{12} receptors cm^{-2}. In this experiment ^{3}H-labelled MOT cells at 5×10^6 per ml were incubated with the indicated concentration of drug for 15 min at room temperature and attachment to the disks determined as discussed in the text. Triplicate samples were assayed, averaged and the data expressed in terms of attachment of untreated cells. ●, Chlorpromazine (Thorazine); △, trifluoperazine (Stelazine); ■, pentobarbital (Nembutal); ○, procaine (Novocain); ◆, lidocaine (Xylocaine). The labelled arrows indicate the concentrations of chlorpromazine (C), trifluoperazine (T) and lidocaine (L) required to inhibit IgG-mediated lymphocyte capping[15].

antipsychotics, anti-inflammatory agents, oestrogens and steroids, fatty acids, anaesthetics, tranquilisers, an anticonvulsant, an alkylating agent, an antifungal antibiotic, an anticoagulant, detergents and an alcohol.

Although inhibition of attachment corresponds to teratogenic activity *in vivo*, failure to inhibit does not correlate as well with lack of teratogenic activity. Table 1 indicates that of 22 drugs found to be non-inhibitory, 14 (64%) were also non-teratogenic *in vivo*. The remaining 8 (36%) thus constitute false negatives (teratogens which do not inhibit attachment). Several of these false negatives are known inhibitors of macromolecular synthesis and would not be expected to have dramatic effects on the cell surface during the 50 min of the assay. Other agents, notably Thalidomide, are believed to be teratogenic by virtue of metabolic products rather than the parent compound[16]. As the current assay system does not include a metabolic activation system, drugs requiring activation would not be expected to inhibit attachment. Recent experiments have shown that treatment of Thalidomide with liver microsomes yields a metabolite which inhibits attachment.

These data suggest that the inhibition of attachment *in vitro* may be useful in the prediction of teratogenic activity *in vivo*. If the five inhibitors of macromolecular synthesis and assembly are excluded, 44 of 50 tested drugs (90%) correctly predict *in vivo* teratogenic response. It is unlikely that the correspondence shown here is completely fortuitous. It is more likely that many teratogens exert their effect by interfering with normal morphological interactions and that these agents also interfere by a similar but unknown mechanism with the energy-dependent tumour cell to lectin surface interaction. However, some of these agents, such as BCNU and busulfan, are probably teratogenic because of their toxicity rather than their interference with cell to cell interactions.

Although the data reported here concern attachment of MOT cells to concanavalin A-derivatised surfaces, we have found identical attachment characteristics with cells from Ehrlich ascites tumour and with cells derived from solid tumours by collagenase digestion. Attachment to surfaces derivatised with lentil lectin or wheat-germ agglutinin was identical to that observed with concanavalin A. Attachment characteristics do not seem to depend on the nature of the plastic surface, as Teflon, Mylar, polycarbonate and acrylic surfaces derivatised with concanavalin A had characteristics identical to the polyethylene surfaces. Scanning electron micrographs of attached cells indicate that attachment is mediated exclusively by numerous filopodia. During the 20-min attachment period, gross spreading of the tumour cells does not occur. However, there is some preliminary evidence that the filopodia extend and arborise during this interval.

If the inhibition of tumour cell attachment to lectin-coated surfaces continues to correlate well with teratogenicity, this inexpensive assay system may prove useful in the rapid identification of potentially teratogenic environmental agents and drugs.

Antibody-mediated enhancement of Flavivirus replication in macrophage-like cell lines

J. S. M. Peiris & J. S. Porterfield

Sir William Dunn School of Pathology, University of Oxford, UK

Interactions between animal viruses and antiviral antisera may exceptionally result in an apparent increase in viral infectivity[1–3]. Halstead and coworkers[4–6] demonstrated enhanced replication of dengue virus (a Flavivirus, family Togaviridae) in human or simian peripheral blood leucocytes carrying Fc receptors at subneutralising concentrations of anti-dengue antibody. We have used three continuous cell lines[7–9] which express macrophage markers to explore the mechanism of this phenomenon. Dengue virus failed to replicate in these cells, but West Nile virus, another Flavivirus, replicated in all three, and we were able to demonstrate reproducibly 50–100-fold enhancement of virus yields in the presence of Flavivirus antisera, the effect also being directly demonstrable in P388D$_1$ cells by increased numbers of virus-induced plaques. The phenomenon of antibody-dependent enhancement of viral replication is not unique to dengue virus, and may have far wider relevance in other viral infections.

P388D$_1$ cells were used[7]. This was continuous line derived from a methyl cholanthrene-induced mouse tumour, which shows a number of macrophage characteristics, for example macrophage-like morphology, immune phagocytosis, Fc and C3 receptors, production of lysozyme, effector functions in antibody-dependent cell mediated cytotoxicity assays, and the absence of surface immunoglobulin[10,11]. Also a second mouse cell line, J774.1 (ref. 8) and a continuous human histiocytic lymphoma cell line, U937 (ref. 9).

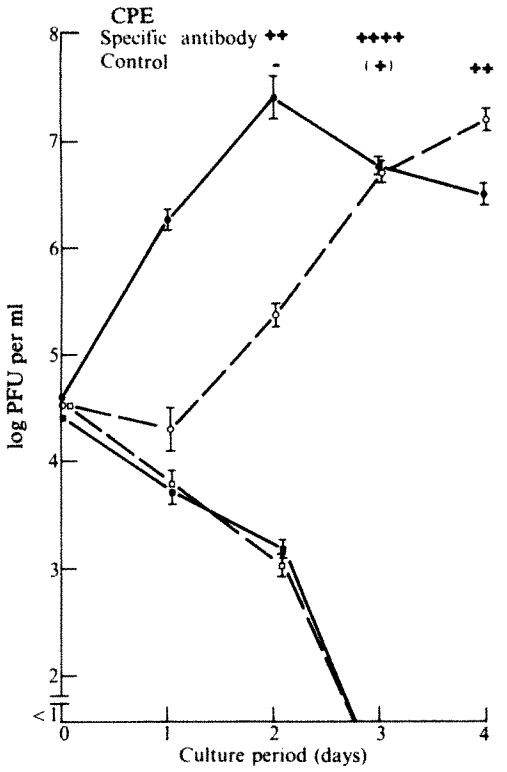

Fig. 1 Effect of specific antibody on West Nile virus yields in $P388D_1$ cells. $P388D_1$ cells (1.3×10^6) in 60 mm Falcon tissue culture dishes were infected with West Nile virus (multiplicity of infection 0.02). Rabbit antibody to normal mouse brain or West Nile virus infected mouse brain at a final dilution of 1:1,000 was added to respective culture dishes. Aliquots of supernatant medium were removed and titrated for virus infectivity in PS cells at days 0, 1, 2 and 3 post-infection. Control tissue culture dishes without cells were set up to estimate thermal inactivation of virus. Each point represents the mean of six titrations, and the 95% confidence limits of the mean is denoted. Infectious virus titre in $P388D_1$ cells in presence of antibody to: ○- - -○ normal mouse brain; ●——● WNV-infected mouse brain. Thermal inactivation of West Nile virus (identical experiment carried out in the absence of $P388D_1$ cells) in presence of antibody to: □ - - -□ normal mouse brain; ■——■ WNV-infected mouse brain. The degree of cytopathic effect in the $P388D_1$ cell monolayer is represented:—no CPE; (+) less than 10% of cells affected; +10–25% cells affected; ++ 25–50% cells affected; +++ 50–75% cells affected; ++++ 75–100% cells affected.

$P388D_1$ cells were grown in MEM-Alpha medium (Gibco-Bio-cult) with 10% heat inactivated fetal calf serum (Sera-Lab) and antibiotics. West Nile virus (WNV) (Egypt 101) stock was a 10% homogenate of infected suckling mouse brain stored in aliquots at −70 °C (infectious titre 2×10^7 plaque forming units (PFU) per ml). A 28-day rabbit antiserum raised against WNV was used in experiments where antibody was added. Titrations of virus infectivity were done using pig kidney PS cells[12]. Figure 1 shows the infectious virus yield from $P388D_1$ cells infected with WNV at a multiplicity of infection of 0.02; in the presence of anti-WNV antibody at subneutralising concentrations this was increased 100-fold in comparison with control cultures. The virus yield from antibody enhanced cultures of $P388D_1$ cells peaks on the second day post-infection, when there were no viable cells left to support viral replication. Yields from control cultures attain the same final virus titre as 'antibody-enhanced' culture plates, but about two days later.

In the presence of antibody, marked cytopathic effect was observed on the second post-infection day which progressed to total destruction of the cell sheet by day 3. In contrast, culture dishes infected in identical conditions without antibody, showed a mild cytopathic effect on day 3 which progressed to total cell destruction on post-infection day 5. Control experiments showed that the effect of the anti-WNV serum was not simply to protect WNV from thermal inactivation. Both the 'enhancement' of replication and the earlier cytopathic effect caused by anti-WNV antibody were reproducible even when unabsorbed virus was removed after the initial infection by two cycles of washing in phosphate-buffered saline.

We next demonstrated antibody-mediated enhancement of WNV plaque formation in $P388D_1$ cells under carboxymethyl cellulose overlay. Figure 2 shows the dramatic increase in the number of plaques resulting from the inclusion of specific antiserum at subneutralising concentrations (final dilution 10^{-3}) in the culture medium. This technique was used to study the ability of a range of antisera at different dilutions to demonstrate antibody-mediated enhancement of plaque formation by WNV (Table 1). Using the anti-WNV serum, it was noted that high concentrations of antibody (up to a final dilution of 10^{-2}) result in neutralisation of plaque formation. At subneutralising concentrations (final dilution $10^{-3} - 10^{-4}$) a 30–40-fold increase in plaque number occurs, and at higher dilutions of antiserum, the plaque counts approach control numbers. Appropriate concentrations of antibody against other relatively closely related (dengue) or more distantly related (Kyasanur Forest disease) Flaviviruses were capable of enhancing WNV, but antisera against the antigenically unrelated Alphavirus, Semliki Forest virus, or against normal mouse brain did not affect the plaque count. This suggests that antibodies to group-specific antigenic determinants are capable of producing enhancement.

Experiments with the cell lines J774.1 and U937 infected with WNV confirm the increased yield shown in $P388D_1$ cells in the presence of specific antiserum, but plaque formation was not possible in these two cell lines. In contrast, virus yields from PS cells (an epithelial cell line of pig kidney origin lacking Fc receptors[13]) were not significantly altered by the presence of 'enhancing' concentrations of antibody (unpublished observations). However, plaque formation by WNV in PS cells seems to be marginally increased by appropriate concentrations of antibody (1.7-fold over control plaque members $P < 0.001$–unpublished observation). In experiments with human peripheral blood leukocytes, WNV shows antibody mediated

Table 1 Enhancement of West Nile virus plaque formation by homologous, cross reacting and non-cross reacting antisera.

Antiserum	'Enhancement factor' at different antibody dilutions						Antibody titre vs. West Nile virus	
	1/25	1/100	1/1000	1/10,000	1/100,000	Control	H.A.I.	PRNT
Pre immune serum	1.4	0.7	1.1	0.7	1.1	1	<10	<10
Anti West Nile immune serum	0	1.0*	20	18	1.2	1	320	64
Anti Dengue type 2 immune serum	12	19	0.7	0.8	1.1	1	20	<10
Anti Kyasanur forest disease immune serum	9	2	0.9	1.2	0.8	1	40	<10
Anti Semliki Forest virus immune serum	1.1	0.8	0.9	0.9	1.2	1	<10	<10

The technique used is as for Fig. 2. The numbers represent the 'enhancement factor' at a given dilution of antibody as calculated by mean PFU in presence of antibody dilution/mean PFU in absence of antibody. The virus input was adjusted to give 5–10PFU in control plates (viz in the absence of antibody). * Plaques were smaller than control. HAI = haemagglutination-inhibition antibody titre. PRNT = plaque reduction neutralisation titre.

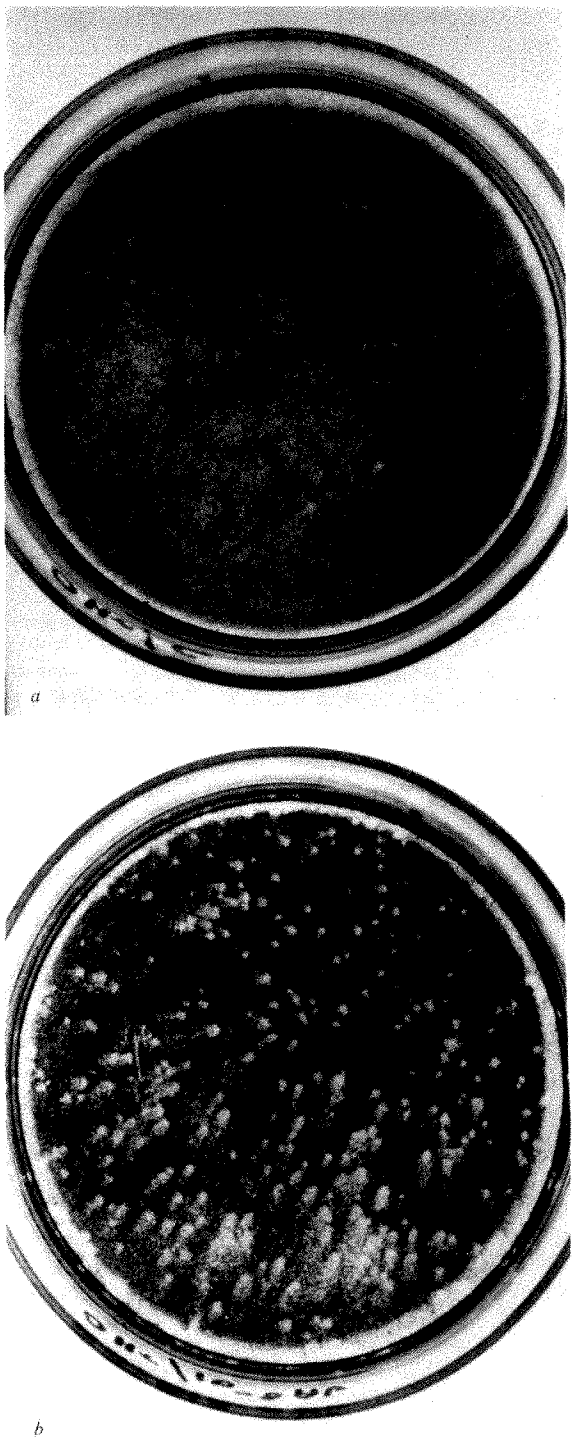

Fig. 2 Enhancement of West Nile plaque formation in P388D$_1$ cells by homologous antibody. 1 ml of virus dilution was mixed with an equal volume of *a*, medium; or *b*, specific antibody at 1 : 1,000 final dilution in 60-mm tissue culture dishes (Falcon). P388D$_1$ cells (1 ml) (1.8×10^6 cells ml^{-1}) was added and culture dishes incubated for 4 h in a CO_2 incubator at 35 °C. Overlay medium (3 ml) containing carboxymethylcellulose (1.5%) was added and culture dishes reincubated for 3 days. At this time the cell monolayer was stained with 1% naphthalene black.

enhancement of virus replication (unpublished observation) thus suggesting that dengue virus is not unique in this respect.

The mechanism of antibody mediated enhancement of viral replication is still open to speculation. The work of Hawkes[1], Halstead and coworkers[4,5] and our own, has been done on cell populations containing mononuclear phagocytic cells (chick embryo fibroblasts have been shown to contain large numbers of phagocytic cells[4]). Fc receptors on such cells may promote the entry of infectious immune complexes formed in the presence of subneutralising concentrations of antibody. Whether antibody directed against a particular antigenic determinant of Flaviviruses is capable of both 'enhancement' and neutralisation depending upon concentration, or whether antibodies of certain specificities are incapable of neutralisation and form 'infectious immune complexes' is uncertain.

The universality of this phenomenon among other virus groups remains to be investigated. Preliminary experiments indicate that antibody also enhances Alphavirus replication in the P388D$_1$ cells (unpublished observations). We believe that the experimental model described could contribute to our understanding of the pathogenesis of diseases such as dengue haemorrhagic fever and other viral infections.

We thank Dr Siamon Gordon for discussions and for providing the macrophage-like cell lines used in this study and Julie Wickson and Alan Hayle for technical assistance. J.S.M.P. was the recipient of a Commonwealth Tropical Medicine Research Grant.

Microtubule organisation in fibroblasts from dystrophic chickens and persons with Duchenne muscular dystrophy

Joe A. Connolly*, Vitauts I. Kalnins* & Brian H. Barber†

* Division of Histology, Department of Anatomy and
† Department of Microbiology and Parasitology, University of Toronto, Canada M5S 1A8

In spite of many attempts to correlate the expression of the Duchenne muscular dystrophy (DMD) genotype with defined phenotypic changes in both muscle and non-muscle cells from affected individuals[1–4], the molecular basis of this X-linked genetic defect has not yet been identified. However, Shay and Fuseler reported recently[5] that interphase cells derived from the muscle of newborn dystrophic chickens had greatly diminished cytoplasmic microtubule complexes, and they speculated that this might be due to a specific defect in the microtubule-organising centres. Insofar as microtubules are a major component of the intracellular cytoskeleton[6], a network thought to interact with the cell-surface membrane[7], the possibility that a microtubule defect might explain the membrane alterations associated with muscular dystrophies[1–4] makes this finding extremely interesting. To assess the generality of this finding with respect to chicken dystrophy and to extend the approach to DMD, we used indirect immunofluorescence with an antiserum to purified brain tubulin to examine the organisation of microtubules in cells from the muscle of dystrophic chickens and in skin fibroblasts from persons with DMD. Unlike Shay and Fuseler[5], we find no lack of a microtubular network in cells derived from cardiac or skeletal muscle of chickens carrying the dystrophic gene (*am*). Furthermore, our examination of fibroblasts from persons with DMD revealed a similar extensive network of microtubules in each case.

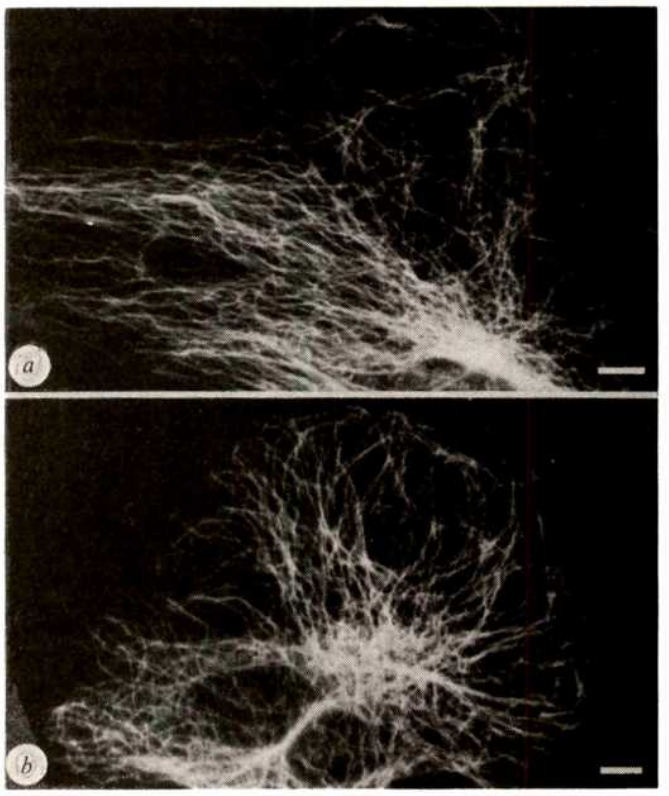

Fig. 1 Fibroblasts prepared by trypsin digestion from 1-d-old dystrophic (*a*) and normal (*b*) chicken muscle stained with antiserum to tubulin. In both cell types a similar cytoplasmic network of microtubules is clearly evident. Scale bar, 5 μm.

To obtain dystrophic chicken cells, we used chickens of the Connecticut line[8]. These birds carry the dystrophic gene (*am*) and are characterised phenotypically by the onset of clinical symptoms 2–3 weeks after hatching[8]. White Leghorn chickens were used as controls. Cells were prepared in one of two ways. (1) A single cell suspension was prepared from trypsinised skeletal muscle tissue[9] and grown to confluency in α-minimal essential medium (MEM) containing 10% fetal bovine serum (FBS). Cells were examined after a single subculture in the same medium. (2) Small pieces of cardiac and skeletal (leg) muscle were placed on 22-mm glass coverslips, allowed to attach for 10 min, and then 2 ml of either α-MEM or CMRL 1066 (GIBCO) culture medium containing 10% horse serum and 5% FBS was added, according to the method of Shay and Fuseler[5]. Cells from these muscle explant cultures were fixed for immunofluorescence after 7 d in culture. Fibroblasts were established in culture from skin biopsies of persons with DMD (three males, 4–5 yr old) and controls of the same sex and approximate age (two males, 4 and 6 yr old). Cells were recovered from storage in liquid nitrogen, and grown at 37 °C under 5% CO_2 in α-MEM supplemented with 15% FBS and antibiotics (100 U per ml penicillin, 100 μg per ml streptomycin). Cells were subcultured routinely every 2–3 weeks and examined by immunofluorescence between the fifth and ninth subculture.

For immunofluorescence, cells were fixed either with methanol followed by acetone at −20 °C (refs 10 and 11), or with methanol alone after treatment with 0.5% Triton X-100 (ref. 12). Fixed cells were incubated with a previously characterised rabbit antiserum to electrophoretically purified pig brain tubulin[10,11] diluted 1:30 in phosphate-buffered saline (PBS) for 40 min at room temperature, washed three times in PBS, and incubated for 30 min with a 1:5 dilution of fluorescein-conjugated goat IgG directed against rabbit IgG (Hyland Diagnostics). Cells were then washed three times in PBS and mounted in 50% glycerol in PBS, *p*H 7.8.

When dystrophic chicken cells, cultured from trypsin-digested muscle or from muscle explants were examined, an extensive network of cytoplasmic microtubules was always seen in more than 98% of the cells (Table 1). Figure 1 shows fibroblasts prepared by trypsin digestion of skeletal muscle from 1-d-old birds. In both dystrophic (Fig. 1*a*) and normal (Fig. 1*b*) cells, the network of cytoplasmic microtubules is clearly evident. Figure 2 shows portions of two cells from explant cultures of dystrophic (Fig. 2*a*) and normal (Fig. 2*b*) skeletal muscle cultured from 15-d-old birds. Again, no obvious differences in the organisation of microtubules were evident. Similar results were obtained independent of the age of the bird from which the cells were cultured, whether skeletal or cardiac muscle was used as the source of cells in explant cultures, and with both fixation procedures. Similar results were also obtained when cells cultured from control birds were examined. These findings are summarised in Table 1. Only very faint diffuse staining was seen when preimmune serum from the same rabbit was used, or when the fluorescein-labelled goat IgG alone was used.

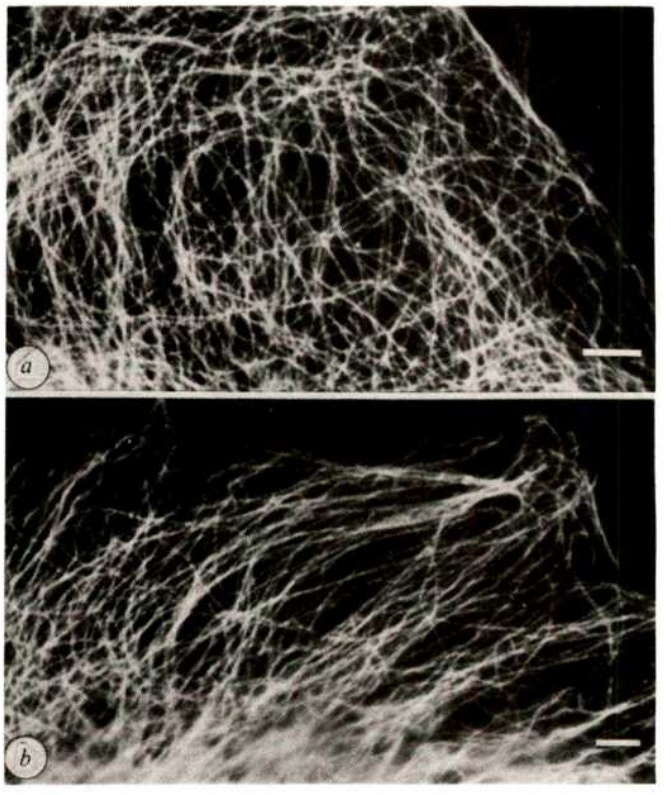

Fig. 2 Cells from dystrophic (*a*) and normal (*b*) explants of skeletal (leg) muscle from 15-d-old chickens stained with antiserum to tubulin. No differences are apparent in these higher magnification views of the microtubular network. Scale bar, 5 μm.

In a complementary study, we also examined microtubule organisation in skin fibroblasts of persons with DMD. In cultured fibroblasts from three individuals with DMD and two controls, no differences were seen between normal and dystrophic cells, and in all cases an extensive network of microtubules was visible in more than 99% of the cells. Figure 3 shows the clearly evident microtubular network present in cultured dystrophic (Fig. 3*a*) and normal(Fig. 3*b*) human skin fibroblasts. Again, similar results were obtained using either fixation method.

We were unable to detect significant differences in the organisation of the cytoplasmic network of microtubules between cells derived from dystrophic chicken muscle and control cells. Likewise, we were unable to detect differences in microtubule organisation between cultured fibroblasts from

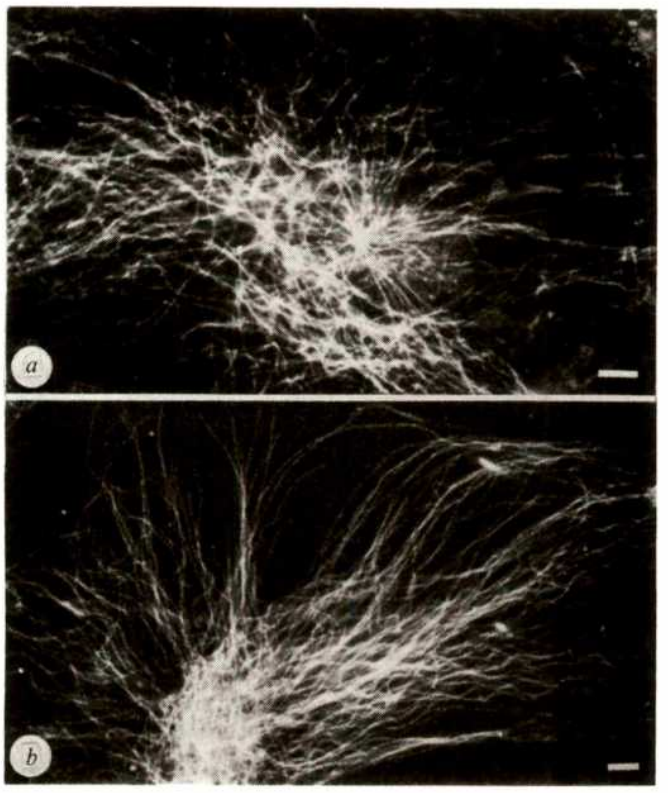

Fig. 3 Human skin fibroblasts from a person with DMD (*a*) and a normal control (*b*) stained with antiserum to tubulin. A similar cytoplasmic network of microtubles is present in both cells. Scale bar, 5 μm.

persons with DMD and control subjects. These results contrast with those reported by Shay and Fuseler[5]. The methods we used for explant cultures were identical to those described in their report[5]. Like Shay and Fuseler, we observed that both normal and dystrophic interphase cells are flat and well-spread on the substrate, and that the distribution of actin in these two cell types is similar (B.H.B., unpublished results). Therefore, we do not understand the discrepancy between their results and ours with respect to the distribution of microtubules in dystrophic cells. The dystrophic chickens from which we prepared our cells were of the Connecticut line, whereas Shay and Fuseler used cells from line 413 birds[5]. Although the difference in genetic background could contribute to the observed differences, it seems unlikely to represent a major factor because both chicken lines are derived from the original 301 dystrophic line, possess the same dystrophic gene (*am*) and are characterised by similar manifestations of the disease[8]. Differences between the antiserum used by Shay and Fuseler and our antiserum may also account in part for the discrepancy in results. However, we believe a more likely explanation lies in the different fixation procedures used and that our methods enhanced the visualisation of microtubules by reducing background staining.

In conclusion, we have been unable to detect major differences in the organisation of microtubules between cells from dystrophic individuals and their corresponding control cells. On the basis of these findings, therefore, we are unable to support any correlation between the expression of the dystrophic genotype and a reduction in the number of microtubules in the interphase cells of affected individuals.

This work was supported by grants from the Ontario Heart Foundation and the MRC of Canada to V.I.K. and from the Muscular Dystrophy Association of Canada to B.H.B. We thank Dr Pat Stewart for dystrophic and normal chickens, Dr M. Thompson for establishing and making available human fibroblast strains, and Dr L. Pierro for maintenance of the chicken cell line. J.A.C. is the recipient of an MRC studentship.

* In each case 200 cells were counted and cells were considered positive only if numerous microtubules of extended length were visible in the cytoplasm.

Different receptors for distribution of peanut and ricin agglutinins between inner and outer segments of rod cells

C. D. B. Bridges & Shao-Ling Fong

Cullen Eye Institute, Baylor College of Medicine, Houston, Texas 77030

Lectins can be used as probes for cell-surface oligosaccharides[1–4]. These proteins display high specificities for certain haptene sugars, although the details of the sugar linkages and the three-dimensional array of the oligosaccharide may all be involved in determining the affinity of a lectin for its receptor. We have now shown that peanut and ricin agglutinins bind differentially to the surfaces of rod inner and outer segments.

Receptors for jack bean lectin (concanavalin A, Con A) are present on the surfaces of rod outer segments (ROS)[5–7]. Con A has a specificity for complex mannose-containing oligosaccharides with internal and terminal *N*-acetylglucosamine residues[8–11] as well as simpler structures containing mannobiosyl units[12]. The high affinity of Con A for rhodopsin[13] is consistent with recent observations showing that its oligosaccharide has the structure GlcNAcβ1→2Manα1→3(Manα1→6)Manβ1→4GlcNAcβ1→4GlcNAc→Asn (refs 14, 15). Because rhodopsin is probably present in the plasma membrane of the ROS as well

0028–0836/79/480513—03$01.00

© 1979 Macmillan Journals Ltd

as the bimembranous disks found in its interior[16,17], it may represent the majority of the Con A receptors. A minor ROS protein, with a molecular weight of 291,000 (refs 18, 19), has also been shown to bind Con A[20], and probably does not play a significant part in binding Con A to the ROS surface.

Some rhodopsin molecules may carry terminal D-galactose residues[21], so we also investigated the galactose-specific agglutinins from *Ricinus communis* (RCA_I) and *Arachis hypogaea* (PNA). These lectins have been used to suggest the existence of terminal galactose units in, for example, normal 3T3, transformed SV3T3, transformed 3T12 cells and embryonal carcinoma cells[22,23].

PNA (L'Industrie Biologique Française) and RCA_I (Sigma and PL-Biochemicals) caused agglutination in suspensions of washed ROS at concentrations of 11 and 25 $\mu g\ ml^{-1}$, respectively. The effect was inhibited by D-galactose at a concentration of 4–40 mM for PNA and 0.3–3 mM for RCA_I. Lactose and α-D-(but not α-L-) fucose inhibited agglutination by RCA_I. Other sugars tested, and found to be ineffective, were α-methyl mannopyranoside, D-glucose, *N*-acetyl glucosamine, chitobiose and *N*-acetyl galactosamine. For comparison, Con A agglutinated ROS at 0.1–0.5 $\mu g\ ml^{-1}$, and was inhibited by α-methyl-mannopyranoside and glucose (see ref. 5).

Fresh ROS from light- or dark-adapted frogs were incubated with fluorescein isothiocyanate (FITC)-labelled PNA or RCA_I and compared, using a Zeiss epifluorescence microscope, with ROS incubated with FITC–Con A. In such preparations a variable proportion of the ROS had part of the inner segment attached. Figure 1 is a typical fluorescence photograph of one of these organelles after incubation with FITC–Con A. Bright surface fluorescence is visible on both the outer and inner segment, showing that receptors for Con A are present at both locations. A brightly fluorescent band delineates the junction between inner and outer segment, perhaps attributable to penetration of the lectin into the few open disks known to occur at that point[24]. The surface fluorescence was virtually abolished if incubation was carried out in the presence of 100 mM α-methyl mannopyranoside.

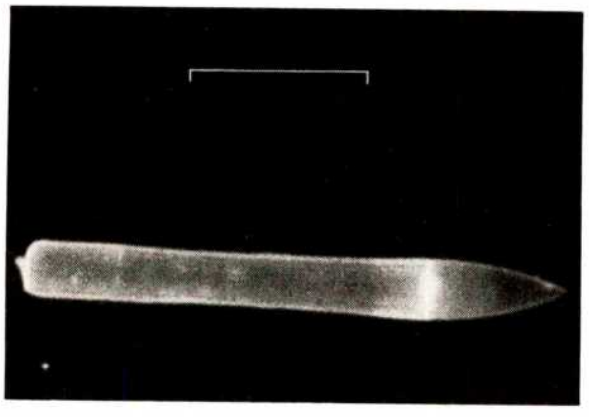

Fig. 1 Fluorescence photograph of an isolated frog (*Rana pipiens*) rod outer segment with part of inner segment attached. FITC–Con A, 100 $\mu g\ ml^{-1}$ in frog Ringer, 12 min incubation at room temperature. Scale bar, 20 μm.

In contrast, Fig. 2 is a similar preparation incubated with FITC–PNA. Although the fluorescence intensity is lower than that for Con A, and hence more difficult to photograph, it can be seen that the bright line of the outer segment surface label stops abruptly at the inner segment, and that there is a dividing line of similar intensity between the two sectors. The diffuse, low-level fluorescence occupying part of the inner segment is autofluorescence which develops in the region of tightly packed mitochondria. It is straw yellow in colour, in contrast to the characteristic green emission of the FITC label. RCA_I gave an

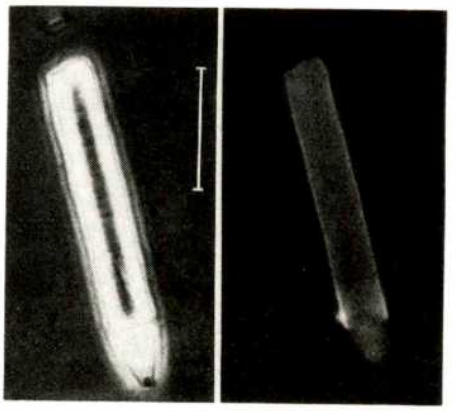

Fig. 2 Preferential binding of FITC–PNA to outer segment plasma membrane. Left hand side, normal phase illumination; right hand side, fluorescence. Both photographs were taken on Kodak Tri-X film pushed to an effective ASA rating of 1,600 with Diafine. Virtually no fluorescence is visible on the plasma membrane of the inner segment; diffuse inner segment fluorescence is autofluorescence from the mitochondria. FITC–PNA, 200 $\mu g\ ml^{-1}$, 12 min at room temperature. Scale bar, 20 μm.

identical pattern of labelling. The binding of both lectins was abolished in the presence of 100 mM D-galactose. After prolonged incubation with high lectin concentrations, a very faint surface label was occasionally seen on the inner segment, but in all cases this was many times weaker than that of the outer segment.

Although PNA has its highest affinity for the disaccharide D-galβ1→3GalNAc (ref. 25), characteristic of many blood glycoproteins, it shares with RCA_I a specificity for the simple terminal sugar D-galactose. The difference between inner and outer segment membranes in their ability to bind RCA_I and PNA suggests that oligosaccharides present on the inner segment plasma membrane lack D-galactose in an accessible, terminal position. Rapid translational and rotational freedom for rhodopsin has been demonstrated in rod disk membranes, indicating that they have an unusually low viscosity[26]. A similar fluidity in the plasma membrane enveloping the whole rod cell would permit RCA_I and PNA receptors to diffuse through the inner–outer segment junction. Their failure to do this may indicate the existence of a barrier at this point, or the plasma membrane may be more rigid than the disk membranes.

The synthetic machinery of the photoreceptor is found in the inner segment, but the finding that oligosaccharides binding RCA_I and PNA are restricted to in the outer segment suggests that only in this region of the cell have they been incorporated into the membrane, or their terminal sugars modified. The receptors themselves may be glycolipids or galactosylated rhodopsin molecules. As noted above, rhodopsin molecules constitute many of the Con A receptors in the outer segment plasma membrane. However, the binding observed on the inner segment (down to the synaptic pedicle in papain-dissociated material) may not involve rhodopsin because Con A binds to sugar sequences common to many glycoproteins[27–29].

We thank the Retina Research Foundation of Houston and the USPHS (National Eye Institute) for financial assistance.

Enkephalins presynaptically inhibit cholinergic transmission in sympathetic ganglia

Shiro Konishi, Akinobu Tsunoo & Masanori Otsuka

Department of Pharmacology, Faculty of Medicine, Tokyo Medical and Dental University, Yushima, Bunkyo-ku, Tokyo, Japan

Recent biochemical and immunohistochemical studies have shown that the opioid peptides, enkephalins, occur in nerve terminals and cell bodies in mammalian sympathetic ganglia[1–3]. Opiates and enkephalins are thought to inhibit synaptic transmission in the peripheral nervous tissues as well as in the central nervous system[4–12]. The mechanisms of the opiate actions, however, are not entirely clear; both pre- and postsynaptic sites of action have been proposed[7–9,11,12]. As acetylcholine is known to be the major neurotransmitter in the autonomic ganglia and as the mechanism of synaptic transmission is well clarified[13], analysis of the peptide action could be more easily but equally usefully carried out in the peripheral synapses than in central synapses. We now report that enkephalins presynaptically inhibit cholinergic transmission in sympathetic ganglia.

The experiments were carried out on the coeliac-superior mesenteric and inferior mesenteric ganglia isolated from male guinea pigs weighing 200–400 g. The animals were stunned and bled. The ganglia together with associated nerves were dissected and incubated with 0.02% collagenase for about 30 min to facilitate microelectrode impalement. The preparations were pinned out in a bath (0.5 ml capacity) made of silicon resin and continuously perfused at a flow rate of 2–4 ml min^{-1} with modified Tyrode solution of the following composition (mM): NaCl, 138.6; KCl, 3.4; $CaCl_2$, 1.3; $MgCl_2$, 1.2; $NaHCO_3$, 21; NaH_2PO_4, 0.6; glucose, 10, equilibrated with 95% O_2 and 5% CO_2. The solution was kept at a temperature of 35–37°C. In some experiments solution containing low calcium (0.7 mM) and high magnesium (2 mM) was used to produce a partial block of synaptic transmission in the ganglia. For stimulating the preganglionic nerve trunks, the greater and/or lesser splanchnic nerves of the coeliac-superior mesenteric ganglion or the lumbar splanchnic and/or intermesenteric nerves of the inferior mesenteric ganglion were drawn into suction electrodes (for the terminology of the nerves see ref. 14). Intracellular recordings were made with glass microelectrodes filled with 2 M potassium acetate, with resistances of 40–80 MΩ. Signals were led to a preamplifier and the output was displayed on an oscilloscope and a pen recorder. A conventional bridge circuit incorporated in the preamplifier was used for recording and passing current pulses through a single microelectrode. Hyperpolarising current was usually injected into the cells to prevent spike generation in response to preganglionic stimulation. In most cases, the size of the response was measured after averaging with a TMC-300 signal averager (Kawasaki). Results were obtained from 53 cells with resting potentials of −45 to −80 mV and action potentials of 70–105 mV.

Met-enkephalin and Leu-enkephalin in concentrations of 0.5–20 μM depressed the excitatory postsynaptic potentials (e.p.s.ps) evoked by preganglionic stimulation in the coeliac-superior mesenteric and inferior mesenteric ganglia. The effect of the peptides was similar in both ganglia. [D-Ala^2]-methionine-enkephalinamide (DAEA), a metabolically stable Met-enkephalin analogue[15], was also effective and had a potency over 30 times higher than that of Met-enkephalin (Fig. 1*A*). The response to DAEA showed neither desensitisation during a 3-min exposure period nor tachyphylaxis with repeated applications when the interval between each application was more than 10 min. The inhibitory effect of DAEA was more marked in low-calcium and high-magnesium solution than in the control solution. DAEA in concentrations of 0.3–2 μM reduced

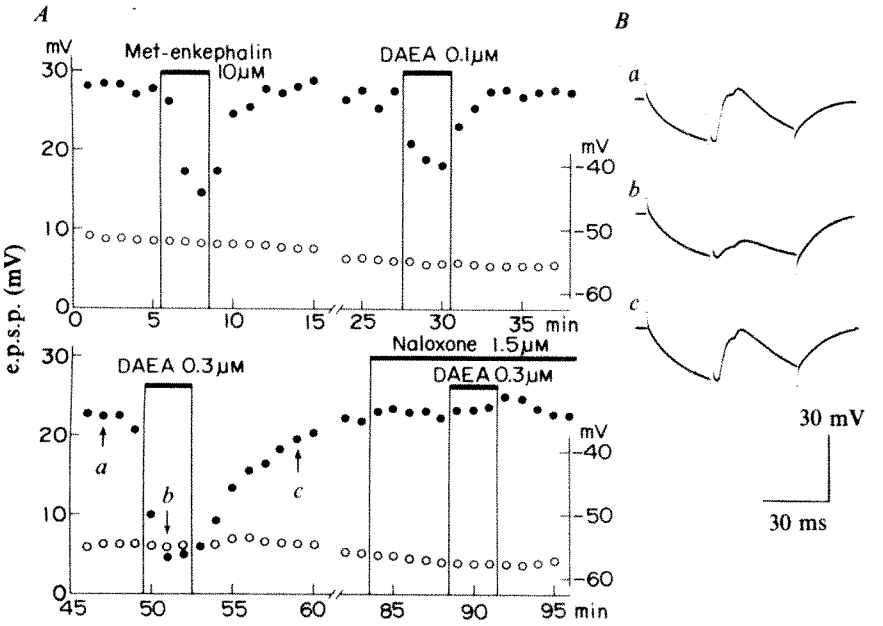

Fig. 1 Effects of Met-enkephalin and DAEA on e.p.s.ps, resting potential and membrane resistance of a postganglionic cell in the inferior mesenteric ganglion, and antagonism by naloxone. The preparation was perfused with solution containing low calcium (0.7 mM) and high magnesium (2 mM) concentrations. Hyperpolarising current pulses of 70 ms duration and 0.5 nA intensity were passed into the cell to prevent spike generation following the e.p.s.p. and also to estimate the membrane resistance. The lumbar splanchnic nerve was stimulated at 1-min intervals for 16 s at 2.5 Hz. *A*, The amplitude of the e.p.s.ps (●) was determined at 1-min intervals after averaging 32 responses. The resting potential (○) was measured from the continuous record of the pen recorder. Ordinate: left, amplitude of the averaged e.p.s.ps; right, resting potential. Each drug was perfused into the bath during the period indicated in the graph. *B*, *a–c*, Sample records of the averaged e.p.s.ps and the potential changes caused by current injection. Records were obtained at arrows *a–c* of *A*.

the amplitude of e.p.s.ps by 52.3±4.4% (mean±s.e.m., n = 14), without significantly affecting either the resting potential (Fig. 1*A*) or the membrane resistance, which was estimated by passing constant hyperpolarising current pulses (Fig. 1*B*) or by observing the current–voltage relationship. The inhibitory effect of DAEA (0.3–1.0 μM) was abolished by the opiate antagonist naloxone (1–3 μM), suggesting that the peptide inhibition results from a specific action on opiate receptors (Fig. 1*A*). Naloxone alone did not produce any consistent change in the size of e.p.s.ps.

number of quanta released by each stimulus. DAEA (1–2 μM) increased the number of failures (see Fig. 2*B*, *C*) and reduced the mean quantum content of the e.p.s.ps to 40–60% of the control (n = 3). However, the peptide did not cause any significant change in the mean amplitude of the quantal unit (Fig. 2*C*). The results support the presynaptic nature of enkephalin-induced inhibition.

We also observed that noradrenaline depressed excitatory synaptic transmission in the coeliac-superior mesenteric ganglion, confirming the previous results of Christ and Nishi[17].

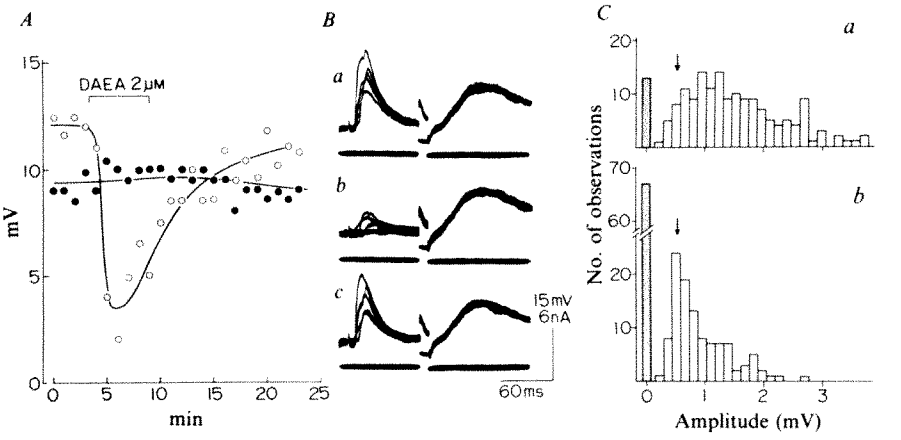

Fig. 2 Effect of DAEA on the e.p.s.p. and acetylcholine-induced depolarisation of the postganglionic cell in the coeliac-superior mesenteric ganglion, and on amplitude histograms of e.p.s.ps. In *A* and *B* the greater splanchnic nerve was stimulated at 1-min intervals by 16 pulses at 0.5 Hz. Acetylcholine was iontophoretically applied to the cell about 80 ms after each nerve stimulus. *A*, The amplitudes of the e.p.s.ps (○) and the acetylcholine-induced depolarisation (●) were determined at 1-min intervals after averaging 16 responses. The peptide was perfused into the bath during the period indicated. *B*, *a*–*c*, Upper trace shows the e.p.s.ps (left) and acetylcholine-induced depolarisation (right), and lower trace shows the current passed into the acetylcholine-containing electrode. *a*, Control; *b*, 2–3 min after addition of DAEA (2 μM). *c*, 7–8 min after washing out DAEA. Hyperpolarising current (0.1 nA) was continuously passed into the cell to prevent spike generation. *A* and *B* were obtained from the same experiment. *C*, Amplitude histograms of e.p.s.ps evoked by stimulation of the greater splanchnic nerve at 2 Hz. *a*, Control; *b*, in DAEA (1 μM). The quantum content, m, was estimated from the numbers of stimuli, n, and failures (stippled bar). The estimated unit sizes of the e.p.s.ps are shown by arrows. For *a* and *b*, respectively, n was 167 and 176, and m was 2.55 and 0.97.

To test the possibility that enkephalins act directly on the postsynaptic membrane and reduce the sensitivity to acetylcholine, the effect of DAEA on acetylcholine response was examined. An intracellular recording electrode was inserted into superficial cells and acetylcholine was applied iontophoretically from another microelectrode placed on the surface of the impaled cells. Short pulse application of acetylcholine produced a depolarisation of the postganglionic cells. The size and time to peak of the depolarisation varied greatly depending on the position of the drug-containing electrode and the applied current. As shown in Fig. 2, the amplitude and time course of the acetylcholine-induced depolarisation were not affected by DAEA, whereas the e.p.s.ps recorded simultaneously were markedly reduced in size. Both the e.p.s.ps and the acetylcholine-induced depolarisation were almost completely abolished by dihydro-β-erythroidine (5 μM). These observations suggest that enkephalins inhibit the release of acetylcholine from the preganglionic terminals but do not reduce the sensitivity of nicotinic receptors on the postganglionic cells.

The undecapeptide, substance P, which also has been demonstrated in the sympathetic ganglia[16], caused a depolarisation of up to 20 mV in certain postganglionic cells. The substance P-induced depolarisation was not depressed by tetrodotoxin (1 μM), which completely blocked synaptic transmission in these ganglia. This suggests that substance P acts directly on the postsynaptic membrane. As observed with the acetylcholine response, the direct depolarising action of substance P(0.4–1.0 μM) was not affected by DAEA (1–2 μM), suggesting that enkephalins have no effect on the chemosensitivity of the postsynaptic membrane.

To confirm the site of enkephalin action, amplitude histograms of e.p.s.ps evoked by preganglionic stimulation at 1–2 Hz in the low calcium (0.7 mM) and high magnesium (2 mM) solution were examined before and after addition of DAEA. Assuming a Poisson distribution of the e.p.s.ps and counting the number of failures in a series of trials, we estimated the mean

However, the possibility that the inhibitory effect of enkephalins might be mediated by the release of a catecholamine was excluded by the observation that the inhibition caused by DAEA (1 μM) was not affected by phentolamine (3 μM), which effectively antagonised the inhibitory effect of noradrenaline (5 μM).

Our results suggest the possible involvement of enkephalins in presynaptic inhibition of cholinergic transmission in mesenteric ganglia. This is particularly relevant to morphological evidence that some of the preganglionic fibres form axo-axonic synapses in the cat inferior mesenteric ganglion[18]. Furthermore, the mode of enkephalin action shown in this study is consistent with recent evidence that enkephalins depress primary afferent transmission in the spinal cord and brain stem, and inhibit the release of substance P, a putative neurotransmitter of the primary afferent fibres[7,8,19].

We thank Dr. T. M. Jessell for reading the manuscript and giving helpful advice.

ADP is a potent inhibitor of human platelet plasma membrane adenylate cyclase

Dermot M. F. Cooper & Martin Rodbell

Section on Membrane Regulation, Laboratory of Nutrition and Endocrinology, NIAMDD, NIH, Bethesda, Maryland 20205

The potent inducer of platelet aggregation, ADP, inhibits both basal and stimulated cyclic AMP production in intact platelets[1,2]. However, several attempts have failed to detect an effect of the nucleotide on adenylate cyclase activity in broken cell preparations[2,3]. This paradox has led to suggestions that ADP may act on unidentified sites before the adenylate cyclase step, such as a nucleoside diphosphate kinase[4] and a Ca^{2+}-transport system[5,6]. It is difficult to demonstrate the effect of physiologically effective concentrations (0.1–5 μM) of ADP on a crude membrane preparation of adenylate cyclase because of the presence of nucleoside phosphohydrolase activities which may degrade either the substrate ATP or the putative effector ADP to products (such as ADP, AMP and adenosine) displaying diverse effects. A substrate regenerating system which converts ADP to ATP obviously provides no solution. The contamination by adenine nucleotides and catecholamines in widely used crude lysate preparations aggravates the problem[7–9]. Using a purified human platelet plasma membrane preparation, and the non-hydrolysable ATP analogue APP(NH)P as substrate, we have now demonstrated direct inhibition of adenylate cyclase by ADP in the physiologically effective concentration range. The inhibitory effect of ADP is immediate in onset and is equal to that produced by adrenaline; it is shared by ADP-βS (and 2′-deoxy ADP to some extent) but not by AP(CH₂)P or other adenine nucleotides. The K_i for ADP is ~0.3 μM and maximal inhibition is observed at 2 μM.

In these studies membranes were prepared essentially as described by Barber and Jamieson[10]. The procedure involves lysis of glycerol-loaded freshly drawn washed human platelets, followed by sucrose gradient centrifugation of the particulate fraction and collection of the plasma membrane-enriched region at 60,000 g. Membranes were washed before use with 0.4 M NaCl in 20 mM Tris, *p*H 7.4, centrifuged at 10,000g, 10 min, 4 °C and resuspended in 10 mM Tris *p*H 7.4 containing 0.1% bovine serum albumin and 0.5 mM EGTA. Assays were carried out at 24°C, generally for 6 min in an incubation volume of 100 μl containing 2–4 μg membrane protein, 0.04% bovine serum albumin, 0.2 mM EGTA, 30 mM Tris *p*H 7.4, 2 mM $MgCl_2$, 40 μM APP(NH)P (Böhringer, lot 31), 1 μCi [α-^{32}P]APP(NH)P, 50 μM cyclic AMP with other additions as indicated. ^{32}P-labelled cyclic AMP was isolated as described elsewhere[11]. Triplicate or quadriplicate determinations of activity were normally performed in a block design and standard deviations of means were generally <5%. When assessed by TLC on PEI-cellulose[12], substrate concentration remained constant (>95%) during the routine assay period.

Table 1 Effect of ADP and related compounds on platelet adenylate cyclase activity

Additions (2.5 μM)	Cyclic AMP (pmol per min per mg protein)	% of control
—	83.8 (5.5)	100
Adenosine	81.2 (1.6)	97
2′-Deoxy AMP	82.4 (1.76)	98
AP(CH₂)P	82.0 (1.09)	98
AMP	79.7 (2.56)	95
2′-Deoxyadenosine	77.0 (3.8)	92
2′-Deoxy ADP	75.6 (3.36)	90
ADP	64.6 (3.15)	77
ADP-βS	63.6 (0.63)	76

Adenylate cyclase activity was determined as described in Fig. 1 legend with both 1 μM PGE_1 and 1 μM GTP in the presence of either 2.5 μM ADP or the related compounds indicated. Values presented are the means ±s.d. of quadruplicate determinations. Activities are also expressed as a percentage of that observed in the absence of the ADP analogues.

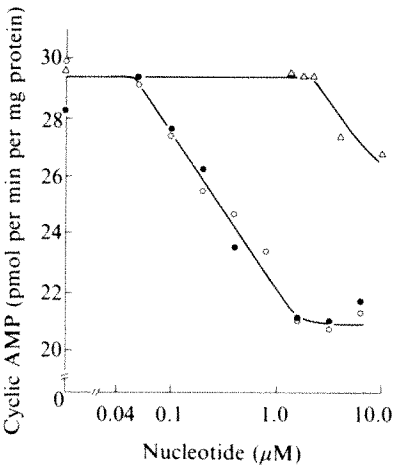

Fig. 1. Effect of ADP, ADP-βS and AP(CH₂)P on human platelet plasma membrane adenylate cyclase activity. Enzyme activity was measured in the presence of 1 μM PGE_1 and 1 μM GTP using 40 μM APP(NH)P, 2 mM $MgCl_2$ and 0.2 mM EGTA in the presence of the indicated concentrations of ADP (●), ADP-βS(○) and AP(CH₂)P (△).

The effects of ADP, ADP-βS (Böhringer) and AP(CH₂)P (ICN) on platelet adenylate cyclase activity are compared in Fig. 1. A potent inhibition of activity (K_i: 0.3 μM) which is maximal at 2 μM is displayed by both ADP and ADP-βS. AP(CH₂)P is only weakly effective. The very similar behaviour of ADP and ADP-βS demonstrates that no phosphorylation of the nucleotide is required for its effect since the thiol analogue cannot be phosphorylated. The ineffectiveness of AP(CH₂)P correlates well with intact platelet studies which showed that this analogue acted only as an antagonist of ADP and was without effect on platelet aggregation[13,14] at physiological *p*H. Evidence has been presented[13] which suggests that part of the ineffectiveness of this analogue resided in the pK_a value of the secondary phosphoryl hydroxyl group, which is 8.0 for the analogue compared with 7.0 for the natural nucleotide[15]. Additionally, altered stereochemistry of the phosphate chain due to the substitution of a (hydrophobic) methylene group has been invoked to account for the lack of effect of the compound[14].

The K_i value of ~0.3 μM for ADP (and ADP-βS) inhibition of adenylate cyclase in the plasma membrane preparation in the present study compares well with the K_i value (0.5 μM) for the inhibition by ADP of cyclic AMP production in intact platelets[2,6]. However, the amount of inhibition (~25%) elicited by ADP in the present study compares with ~90% inhibition of cyclic AMP production in intact platelets. No immediate explanation for this discrepancy is available, but it may suggest either the unmasking of additional pools of adenylate cyclase or some deregulation of the activity on the disruption of cells and preparation of membranes. There was a similar degree of inhibition of fat cell adenylate cyclase by adenosine analogues which was observed as a dramatic reduction in cellular cyclic AMP levels[16]. Sabol and Nirenberg[17] reported similar levels of inhibition of neuroblastoma–glioma hybrid adenylate cyclase by α-adrenergic agents and other opiates.

The effects of a more extensive range of ADP concentrations were also examined. After the sensitive phase of ADP inhibition

0028–0836/79/480517—02$01.00

© 1979 Macmillan Journals Ltd

which is complete at 2 μM (compare Fig. 1), a plateau in activity follows. Further inhibition is evoked by concentrations >40 μM(K_i~200 μM), which presumably represents competition of ADP for substrate at the catalytic site (results not shown).

PGE_1-stimulated activity with and without GTP is shown as a function of time in the presence and absence of 2 μM ADP in Fig. 2. Activities are linear for 10 min in the absence of ADP. Inhibition by ADP is immediate in onset and is maintained throughout the usual assay period (6 min). After 6 min there is some diminution in the amount of inhibition caused by ADP, which may reflect ADP metabolism.

Degradation of ^{14}C-ADP (2 μM) during the routine assay period (6 min) was assessed by TLC on PEI-cellulose[12] of an aliquot of reaction mixture to which [α-^{32}P]APP(NH)P had not been added. At least 85% of the radioactivity applied was recovered in the ADP region in two determinations (results not shown). The low level of degradation of ADP by a plasma membrane preparation, presumably containing nucleotide phosphohydrolases, may reflect protection of the diphosphate by the adenylate cyclase substrate, APP(NH)P.

In Table 1 the effect of ADP on platelet adenylate cyclase is compared with that of ADP analogues and related compounds. ADP and ADP-βS yield equal inhibition, AP(CH_2)P is ineffective and 2'-dADP gives intermediate results. The relative ineffectiveness of AMP, dAMP, adenosine and 2'-deoxyadenosine underline the fact that ADP and ADP-βS act on a receptor which is specific for ADP as first suggested by Born[18]. The weak inhibition by 2'-deoxyadenosine may be viewed as an interaction with inhibitory adenosine sites described previously[9,19].

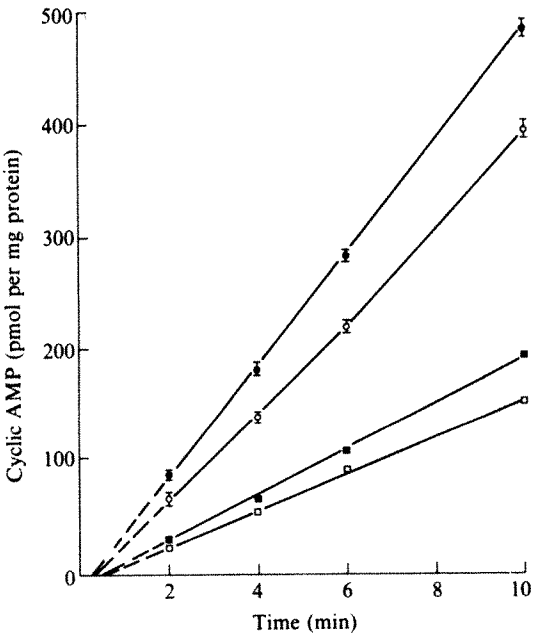

Fig. 2 Time course of the effect of ADP on adenylate cyclase activity of platelet plasma membranes. Cyclic AMP accumulation was measured at the times indicated in the conditions described in Fig. 1 in the presence of 1 μM PGE_1 alone (■, □) or in combination with 1 μM GTP (●, ○) without (●, ■) or with (○, □) 2 μM ADP. Standard deviations of triplicate determinations are shown for the upper two lines.

Table 2 shows the inhibition by ADP of various activity states of platelet adenylate cyclase activity. Clearly the greatest absolute amount of inhibition is obtained with maximally stimulated activities. It is not so clear whether the ADP inhibition is preferentially directed towards a particular state. A notable feature is that the amount of inhibition evoked by ADP is equivalent to that produced by adrenaline in this experiment.

Table 2 Effect of ADP on variously stimulated platelet adenylate cyclase

	Cyclic AMP (pmol per min per mg protein)		
Additions	−ADP	+ADP(2 μM)	% activity in absence of ADP
GTP (1 μM)	4.79 (0.29)	3.5 (0.15)	73
GTP + PGE_1 (1 μM)	72.9 (4.4)	56.9 (1.02)	78
GTP + EPI (10 μM)	3.74 (0.46)	3.44 (0.33)	92
GTP + EPI + PGE_1	51.0 (4.1)	44.8 (1.17)	88

Adenylate cyclase activity was determined as described in Fig. 1 in the presence or absence of 2.5 μM ADP with 1 μM GTP, 1 μM PGE_1 and 10 μM (−)L-adrenaline as indicated. Values presented are the mean ± s.d. of quadruplicate determinations. Activities are also expressed as a percentage of that observed in the absence of ADP.

Jakobs *et al.*[8] reported a similar degree of inhibition of platelet adenylate cyclase by adrenaline. Interestingly, the combination of ADP and adrenaline yields a total of 40% inhibition of activity relative to control values (Table 2, 72.9 to 44.8) but the relative amount of inhibition induced by ADP is diminished in the presence of adrenaline and vice versa. These findings suggest that the two agents converge on a common pool of catalytic activity.

The present report has described a direct inhibition of platelet plasma membrane adenylate cyclase activity by ADP in the same concentration range as that which is effective in both reducing cyclic AMP production in intact platelets and promoting platelet aggregation. The detection of this effect of ADP on a membrane adenylate cyclase also opens up the possibility of detecting such effects on the enzyme in other systems. Primary candidates are those physiological systems thought to be mediated by 'purinergic receptors' as described by Burnstock[20] and those systems in which adenylate cyclase shows different behaviour when APP(NH)P rather than ATP is used as substrate (compare ref. 21).

ADP inhibits as effectively as adrenaline in this system. A combination of the two agents evokes greater inhibition than that elicited by either agent alone. Precisely how these effectors interact in the regulation of platelet adenylate cyclase remains to be established. However, it is possible that this interaction may serve as a model of the means whereby neurotransmitters and adenine nucleotides, which are commonly secreted together in synapses, participate in the 'neuromodulation' of physiological events[20].

We thank Drs G. A. Jamieson and M. Markham for advice and assistance in the preparation of platelet plasma membranes and Drs C. Londos, M. C. Lin and T. Nielsen for helpful criticism.

Concentration dependence of currents through single sodium-selective pores in frog skin

W. Van Driessche* & B. Lindemann†

* Laboratorium voor Fysiologie, Universiteit Leuven, Belgium
† Abteilung für Membranforschung an Epithelien, Second Department of Physiology, D-6650 Hamburg, FRG

Many transport processes in biological membranes show a saturation of transport rate when the concentration of the transported ions or molecules is sufficiently increased. Saturation will result when at high concentrations a translocation step which does not directly depend on bulk concentration becomes rate limiting, and it is expected for all multi-step translocation mechanisms. However, a possible alternative explanation for saturation is a regulatory process which decreases the number of translocating channels in response to an increase in bulk concentration of the transported species. In the frog epidermis, Na^+ uptake from the extracellular space into the epithelial cytosol occurs through Na^+-selective, passively conducting channels located in the apical membrane of the cells directly below the cornified outer cell layer. Saturation of transport occurs with increasing outer Na^+ activity ($[Na]_o$): the net Na^+ current[1,2], membrane conductance[2,3] and unidirectional Na^+ influx[4] increase only subproportionally with $[Na]_o$. The apical Na^+ current can transiently be larger than the saturation value, suggesting that a fixed upper single channel transport rate is not responsible for the saturation, and it has, therefore been suggested that in this case saturation occurs through a $[Na]_o$-dependent decrease in channel density[2]. The Na^+-translocation process can be investigated by a statistical evaluation of spontaneous transport fluctuations. The reversible transport blocker amiloride can be used to induce random fluctuations of the Na^+ current at the apical membrane. The power density spectrum of these fluctuations is of the lorentzian type and permits an estimation of the Na^+ current which passes through individual translocators in the time intervals between blocks[5]. We have recorded the current fluctuations at different $[Na]_o$ values and different amiloride concentrations in the $[Na]_o$ range in which saturation of total Na^+ current is observed. We report here that the density of the conducting pores decreases with increasing $[Na]_o$.

The experimental technique was similar to that described previously[5]. We used abdominal skins of *Rana esculenta* at room temperature in a Lucite chamber with 3 cm^2 exposed to the bathing solutions. The tissue was held by silicon rings (Silgel 604, Wacker Chemie) to avoid damage to the edges. The inner solution was K^+-sulphate Ringer, which would be expected to depolarise the K^+-selective inward-facing membranes of the epithelium and produce a four- to five-fold increase in their conductance. At high inner K^+ concentrations the epithelium (judged by its current–voltage curve) behaves approximately like a one-membrane preparation[2]. Transepithelial resistance and potential are then largely determined by the Na^+-selective, outward-facing membrane. This situation was further improved by using amiloride to increase the resistance of this membrane. The outer solution was sulphate Ringer in which the Na^+ concentration was varied by substitution with K^+. An activity coefficient of 0.55 was used to compute Na^+ activities[2,6]. We used $[Na]_o$ values of 6–60 mM and amiloride concentrations, $[A]_o$, of 1–16 μM for fluctuation analysis. I_{Na}, the transcellular current component which could be blocked by amiloride, was determined as described elsewhere[5]. The transepithelial voltage (V) was clamped to zero with a voltage-clamp circuit designed for low-noise applications[7]. The fluctuating component of the feedback current was amplified and sampled as described previously[5,8].

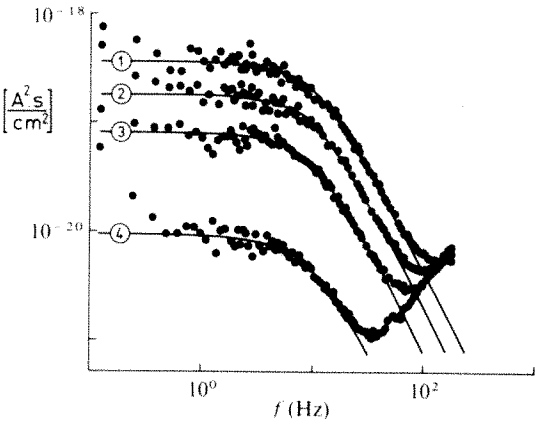

Fig. 1 Power density spectra obtained at constant amiloride concentration (4 μM) and four values of $[Na]_o$, as indicated. Power densities are normalised to 1 cm^2. It can be seen that a 10-fold variation in $[Na]_o$ causes significantly less than a 100-fold variation in S_0^A (plateaus of Lorentz curves), and a small change of the corner frequency f_c^A. In the high frequency range the excess noise becomes smaller than the amplifier noise, which increases because of the decrease in the membrane impedance at high frequencies. Respective values for f_c^A (Hz) and $[Na]_o$ (mM) are: ① 10.5, 60; ②, 10.4, 30; ③, 9.5, 18; ④, 9.3, 6.

In agreement with previous results, the amiloride-induced component of the spectrum of the Na^+ current was found to have a corner frequency, f_c^A, which increased with the amiloride concentration, whereas the plateau values S_o^A, of the corresponding lorentzian curve decreased. f_c^A increased linearly with $[A]_o$ values between 3 and 12 μM, and so the amiloride–receptor reaction could be described by first order kinetics using the reaction rate ($1/\tau$)

$$2\pi f_c = \frac{1}{\tau} = k_1'(A)_o + k_2 \qquad (1)$$

where k_1' represents the apparent association rate constant, k_2 the dissociation rate constant and τ the relaxation time constant[5]. Corner frequencies smaller than predicted by this straight-line relationship were often found with $[A]_o$ values of 1, 2 and 16 μM. At these amiloride concentrations the power density spectra usually deviated markedly from the lorentzian, probably because of additive spectral components— at low $[A_o]$ the amiloride spectrum is too close to the spectrum of the spontaneous fluctuations to be easily evaluated, and at high $[A]_o$ it is too close to the background spectrum obtained from the epithelium in Na^+-free solutions. Therefore, we have restricted our analysis to amiloride concentrations between 3 and 12 μM. At constant $[A]_o$, f_c^A increased by about 1 Hz in response to a 10-fold increase in $[Na]_o$ (see Fig. 1). With $[Na]_o = 60$ mM, $2\pi f_c^A$ was calculated to be $62.1 \pm 1.7\ s^{-1}$ at $[A]_o = 4$ μM ($n = 10$), and $115.9 \pm 3.2\ s^{-1}$ at $[A]_o = 8$ μM ($n = 10$). From the shift of f_c^A with

Table 1 The rate constant k_1' and the factor G in equation (2) which are approximately independent of $[Na]_o$

$[Na]_o$ (mM)	k_1' ($\mu M^{-1}\ s^{-1}$)	$G \times 10^3$ (s) $[A]_o = 4$ μM	$[A]_o = 8$ μM
6	13.6 ± 0.4	14.8 ± 1.4	7.9 ± 0.5
20	12.4 ± 0.5	14.2 ± 1.2	8.3 ± 0.6
30	13.0 ± 0.6	12.7 ± 0.5	7.9 ± 0.3
45	12.5 ± 0.4	12.0 ± 0.5	6.7 ± 0.2
60	12.2 ± 0.3	13.0 ± 0.7	7.5 ± 0.5

G was calculated for two values of $[A]_o$. Each value corresponds to the mean ± s.e.m. of six observations.

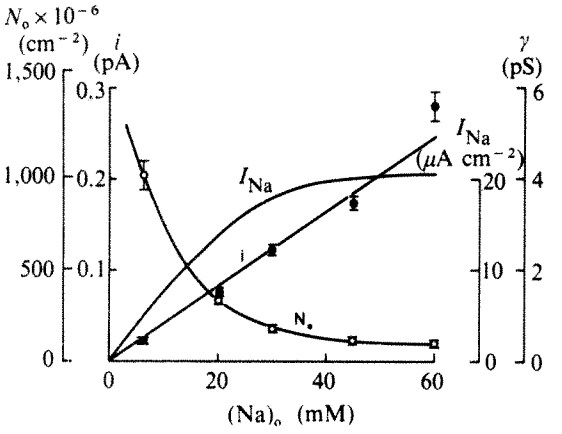

Fig. 2 ●, Computed values (equation (2)) of Na^+ current (i) through single conducting pores at different outer Na^+ activities. Spectra obtained with an amiloride concentration of 6 μM were used ($n = 7$). Bars represent s.e.m. The conductance (pS) of single open pores was computed using equation (3). ○, The densities of conducting pores (N_o). The curve labelled I_{Na} represents the total amiloride-sensitive Na^+ current which passed 1 cm^2 of epithelium in the absence of amiloride in the experiment represented by the data points.

$[A]_o$ (equation (1)) we calculated, for different sodium activities, tentative values for k_1', k_2 and the apparent dissociation constant K_A'. k_1', which is the slope of the straight line through the data points of the rate/concentration plot, could be determined quite accurately. However, there was a greater experimental variation in k_2 and K_A', which are, respectively, the intercept with the ordinate and abscissa. Table 1 lists the values for k_1' obtained at different Na^+ concentrations. k_1' does not change significantly with $[Na]_o$, whereas the apparent value of k_2 increases with $[Na]_o$. The apparent mean lifetime of the amiloride–receptor complex calculated from these k_2 values was 75 ± 2 ms and 382 ± 75 ms, respectively, at $[Na]_o$ 60 mM ($n = 61$) and 20 mM ($n = 24$).

The current, i, passing through single open pores was calculated from Lorentz spectra using

$$i = S_o^{\wedge}/(4aGI_{Na}) \qquad (2)$$

where $G = (2\pi f_c^{\wedge})^{-2} \times k_1' \times [A]_o$. Equation (2) is equivalent to equation (6) derived in ref. 5. a denotes the membrane area and I_{Na} the mean net Na^+ current per cm^2 observed while current fluctuations were being registered. We found that $S_o^{\wedge}$ and I_{Na} changed with $[Na]_o$, whereas k_1' and $f_c^{\wedge}$ remained almost constant. Therefore, the factor G remains approximately constant as long as $[A]_o$ does not change (see Table 1). The computed values of i are shown in Fig. 2 as a function of $[Na]_o$. The current through single conducting pores can be seen to increase linearly with the outer Na^+ activity, although the mean net Na^+ current becomes saturated (Fig. 2, curve labelled I_{Na}). This result supports the previous conclusion[2] that the transport capacity of individual channels (pores) cannot be responsible for the saturation of net Na^+ uptake with increasing $[Na]_o$.

The change of i with $[Na]_o$ enables the conductance of single open pores to be calculated. The current–voltage curve of the Na^+-selective membrane can be predicted by the constant field equation[2]. Assuming the intracellular Na^+ concentration to be negligible relative to $[Na]_o$ in the amiloride concentration range used, the slope conductance of the single open pore (γ) can be approximately estimated at zero voltage across the apical membrane as

$$\gamma = \frac{i}{2RT/F} \qquad (3)$$

R, T and F have their usual meaning. γ is thus proportional to i, and so increases linearly with $[Na]_o$. The appropriate ordinate scale for γ has been included in Fig. 2. Mean values of 5.5 pS are reached at $[Na]_o$ values of 60 mM.

Knowing the dependence of i on $[Na]_o$, the expected change in the density of conducting pores, N_o, with $[Na]_o$ can be calculated from the expression $N_o = I_{Na}/i$. Using this, we do, indeed, find that N_o decreases with increasing $[Na]_o$ (Fig. 2), thus confirming our hypothesis that the saturation of Na^+ transport with increasing $[Na]_o$ is caused by a decrease in the number of conducting translocators. This regulatory 'inactivation' of transporting channels may prevent Na^+ overloading of the epithelial cells in situations in which there is a large environmental Na^+ supply.

A plasma membrane anion exchange system allows the red blood cell to replace intracellular bicarbonate rapidly with extracellular chloride to facilitate carbon dioxide release into the lungs. The protein responsible for this exchange is a glycoprotein of molecular weight about 93,000, called band 3, which comprises approximately 25% of the total red cell membrane protein and is present in the membrane as a non-covalent dimer[1]. The molecular mechanism of anion transport remains obscure, in spite of the characterisation of the extracellular anion binding site by a number of methods including interactions with disulphonic stilbene probes which act as specific inhibitors of anion exchange[2]. One of these compounds (4,4'-diisothiocyano-2,2'-disulphonic stilbene; DIDS) causes complete inhibition of anion exchange by reacting at approximately one site per band 3 monomer (~2.5 nmol per mg protein)[3]. A fluorescent DIDS analogue, DBDS (4,4'-dibenzoamide-2,2'-disulphonic stilbene), binds reversibly and specifically to the DIDS reactive site where it also inhibits anion exchange[6]. When bound, the fluorescence intensity of DBDS increases by two orders of magnitude and this has enabled us to investigate the binding kinetics of DBDS to red blood cell ghost membranes by fluorescence equilibrium and temperature-jump methods. Our equilibrium binding data indicate that there are two classes of DBDS binding sites on red cell ghosts. The reaction scheme that we present here suggests that the apparent high affinity (15–60 nM) for binding the first DBDS molecule is the result of a two step process: an initial binding of lower affinity (K_1~0.5 μM) to band 3 followed by a slow conformational change (~5 s^{-1}) in the binding site which acts to lock the DBDS molecule in place. A second DBDS molecule binds with low affinity (~3 μM) to a site which is more difficult to characterise.

The equilibrium binding affinities for DBDS binding to red cell ghosts were determined as described in Fig. 1 legend. All equilibrium and relaxation experiments were conducted in 28.5 mM sodium citrate, pH 7.4 (160 mM ionic strength). No transportable anions were present so that the system could be

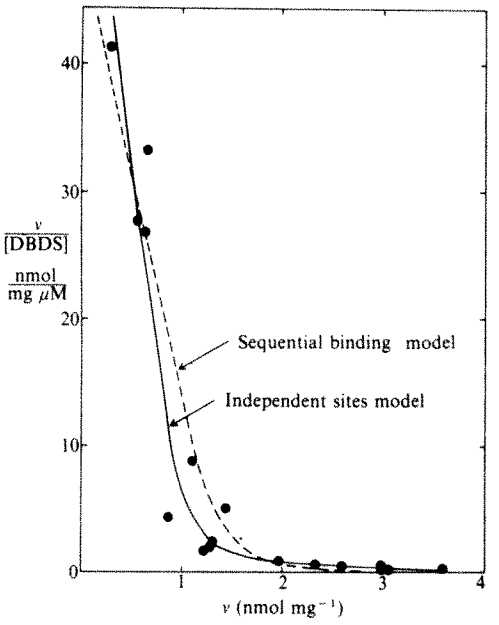

Fig. 1 A Scatchard plot of DBDS binding to red cell ghosts. ν is the DBDS (nmol) bound per mg of ghost protein and [DBDS] is the concentration of unbound DBDS. Ghosts (prepared by standard procedures[4]) were incubated with known concentrations of DBDS for 1 h in 28.5 mM sodium citrate, *p*H 7.4, 25 °C and then centrifuged at 40,000*g* for 15 min. The concentration of DBDS in the supernatant was determined by absorbance at 336 nm or by fluorescence (excitation 336 nm, emission 435 nm). The quantity of DBDS bound was determined from the difference between total and free. The ghost concentration (determined by the Lowry[5] procedure) varied between 0.4 and 1.3 mg ml^{-1}. The solid line was drawn using the equation: $\nu/[DBDS] = n_1/([DBDS]+K_1') + n_2/([DBDS]+K_2')$ which assumes two independent binding sites with $n_1 = 1.0$ nmol mg^{-1}, $K_1' = 16$ nM and $n_2 = 2.7$ nmol mg^{-1}, $K_2' = 4.4$ μM. The dotted line was drawn using the equation: $\nu/[DBDS] = 2n(K_2^a + [DBDS])/(K_1^a K_2^a + 2[DBDS](K_2^a + [DBDS]/2))$ which assumes two identical interacting sites, each with stoichiometry $n = 1.36$ nmol mg^{-1} and with intrinsic dissociation constants for the first and second ligand of $K_1^a = 56$ nM and $K_2^a = 1.86$ μM.

studied in simple conditions. The curved Scatchard plot in Fig. 1 can be explained on the basis of two classes of independent sites (solid line) or negative cooperativity in DBDS binding to identical sites (dashed line). The high affinity DBDS binding may be completely eliminated by reacting whole cells with DIDS before ghost cell preparation[6]. However, the maximum specific incorporation of DIDS (or BIDS[6]; 4-benzoamido-4'-isothiocyano-2,2'-disulphonic stilbene) into band 3 is approximately 2.5 nmol per mg ghost protein while the stoichiometry of the apparent high affinity site ($K_1' = 16$ nM, independent binding site model) is only 1–1.3 nmol per mg. It is not clear how much, if any, of the low affinity binding is on band 3. Equilibrium binding affinities determined by fluorescence enhancement (data not shown) closely paralleled the results shown in Fig. 1.

The rate constants for DBDS equilibration with the ghost membrane were determined by the temperature-jump method[7]. As illustrated in Fig. 2, a rapid decrease in DBDS fluorescence occurred during the instrument heating time (~5 μs) corresponding to a rapid decrease in the quantum yield of DBDS; this was followed by a slower exponential decay in fluorescence on the millisecond time scale. The slow decay was not observed with sonicated lipids extracted from red cell ghosts and the amplitude (corrected for inner filter effects) of the relaxation decreased by over 95% after incubation with 4 μM DIDS indicating that the fluorescence decrease is primarily due to the release of DBDS from band 3.

The concentration dependence of the exponential relaxation is presented in Fig. 3*a*. At high concentrations of free DBDS, the apparent rate constant ($1/\tau$) becomes independent of concentration. These data require a minimal model consisting of a single bimolecular step in which DBDS rapidly binds to its receptor, R, followed by a slow concentration-independent conformational change:

$$DBDS + R \overset{K_1}{\longleftrightarrow} R{\cdot}DBDS \underset{k_{-2}}{\overset{k_2}{\longleftrightarrow}} R'{\cdot}DBDS$$

The relaxation expression for this model is given in the legend to Fig. 3*a*. The straight line in the inset is the best fit subject to the constraint that the equilibrium dissociation constant is 16 nM as determined for the high affinity site of the independent site model in Fig. 1 ($K_1' = K_1/[1+(k_2/k_{-2})] = 16$ nM); the free ligand and site concentrations are given by the equilibrium data. The model did not fit the data well at low DBDS concentrations and, if K_1' was not constrained, k_{-2} became negative.

We therefore explored a model in which a second DBDS molecule is assumed to bind rapidly but weakly to the receptor following the conformational change:

$$R \overset{K_1}{\longleftrightarrow} R{\cdot}DBDS \underset{k_{-2}}{\overset{k_2}{\longleftrightarrow}} R'{\cdot}DBDS \overset{K_3}{\longleftrightarrow} R'{\cdot}(DBDS)_2$$
$$\qquad\qquad\qquad

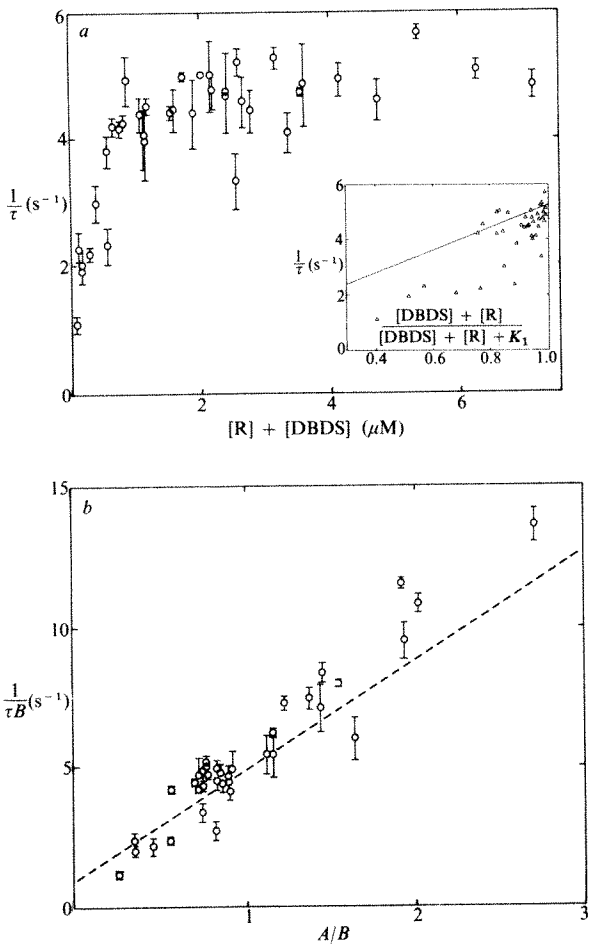

Fig. 3 *a*, Kinetics of DBDS binding to band 3. The abscissa values, the sum of the free concentrations of DBDS and receptor, are determined from the equilibrium binding data shown in Fig. 1 for the independent site model. The ordinate, $1/\tau$, is the reciprocal time constant obtained from a fit to relaxation data. Each data point represents an average of four experiments; error bars indicate one standard deviation from the mean. These data require a minimal mechanism consisting of a rapid bimolecular step followed by a slower conformational change. The relaxation expression for this model (see inset) is $1/\tau = k_{-2} + k_2([DBDS]+[R])/(K_1+[DBDS]+[R])$, where [DBDS] and [R] are the free concentrations of DBDS and receptor sites calculated from the high affinity independent site model binding data of Fig. 1 and the constants defined in the text. The solid line is the best fit using the assumptions in the text with $k_{-2} = 2.3\ s^{-1}$ and $k_2 = 3.3\ s^{-1}$. The effect of the low affinity independent site on the relaxation times predicted by this minimal model have been neglected for simplicity. A fit which includes the effect of the second binding site is similar to that obtained with the minimal model[10]. *b*, A fit of the relaxation expression for the three step model to the experimental data. Assuming rapid equilibrium for the two binding steps, K_1 and K_3, the relaxation rate as determined by standard procedures[9] is $1/\tau = k_2A + k_{-2}B$ where:

$$A = 1 - \frac{yK_1/2 - [R][DBDS]}{xy - 2[R]^2[DBDS]/K_1K_2}$$

$$B = 1 - \frac{x[DBDS] - [R][DBDS]/K_2}{xy - 2[R]^2[DBDS]/K_1K_2}$$

$$x = [R] + [DBDS] + K_1/2$$

$$y = [DBDS](1 + 2[R]/K_1K_2) + 2K_3$$

$$K_2 = k_{-2}/k_2$$

The solid line through the data is the best fit ($r = 0.94$) with the constraints that $K_1 = K_1^a(1 + k_2/k_{-2}) = 56\ nM(1 + k_2/k_2)$ and $K_3 = K_2^a/(1 + k_{-2}/k_2) = 1.86\ \mu M/(1 + k_2/k_2)$ as determined from the negative cooperativity model in Fig. 1. [R] and [DBDS] are the concentrations of unoccupied sites and free DBDS as determined from the data in Fig. 1. The values determined for k_2 and k_{-2} were $4.4\ s^{-1}$ and $1.0\ s^{-1}$ respectively.

0028-0836/79/480522—03$01.00

locks the first DBDS molecule to the receptor site; subsequently a second DBDS molecule binds to a second site with lower affinity. These studies also illustrate the value of the temperature-jump technique in examining the detailed mechanism of membrane transport reactions.

Distribution of light chains in fast skeletal myosin

Susan Lowey, Pamela A. Benfield, Laura Silberstein & Leslie M. Lang

Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, Massachusetts 02254

Myosin is composed of two heavy chains of molecular weight 200,000 and four light chains of approximate molecular weight 20,000. The heavy chains are organised into a two-headed structure of which each head is completed by the presence of two light chains[1,2]. In fast skeletal myosin the light chains can be divided into two classes which are chemically and functionally distinct. One member of each class is associated with each head. The class known as the alkali light chain contains two related variants: alkali 1 (A1) and alkali 2 (A2). These light chains are identical in amino acid sequence over their C-terminal 141 residues, but differ in their N-terminal sequences[3]. The non-integral stoichiometry of light chains in rabbit skeletal myosin[4,5] first suggested that at least some myosins must be homodimeric (a molecule with the same light chain on each head), but it was not clear to what extent heterodimers (molecules containing both alkali 1 and alkali 2 light chains) also occurred. The most direct approach to determining the distribution of light chains in myosin is to isolate the different myosin isoenzymes. Although ion-exchange chromatography has been successful in separating the single-headed sub-fragments of myosin[6], it has not been possible to fractionate double-headed species except by some type of affinity chromatography[7,8]. We have shown that homodimers of myosin can be isolated from chicken pectoralis myosin by immunological methods[9,10]. By comparing the electrophoretic patterns of homodimeric molecules with whole myosin in non-denaturing gels, it has been possible to demonstrate conclusively the existence of a light chain heterodimer.

Antibodies specific for the N-terminal sequence of alkali 1 or alkali 2 can be used as immunoadsorbents to fractionate heavy meromyosin or myosin into two components[9,10]. When myosin is passed through an affinity column prepared by coupling antibody to Sepharose, a fraction rich in alkali 1 (Fig. 1*b*) or alkali 2 (Fig. 1*c*) is obtained in the void volume, depending on the specificity of the column. The retained myosin fraction can only be eluted by a denaturant such as guanidine hydrochloride, or a weak acid. It is evident that the isolated homodimers are both slightly contaminated by the heterologous light chain: that is, A1 myosin contains about 10% alkali 2 light chain (Fig. 1*b*) and A2 myosin is contaminated by a similar amount of alkali 1 light chain (Fig. 1*c*). The antibody-bound myosin (not shown

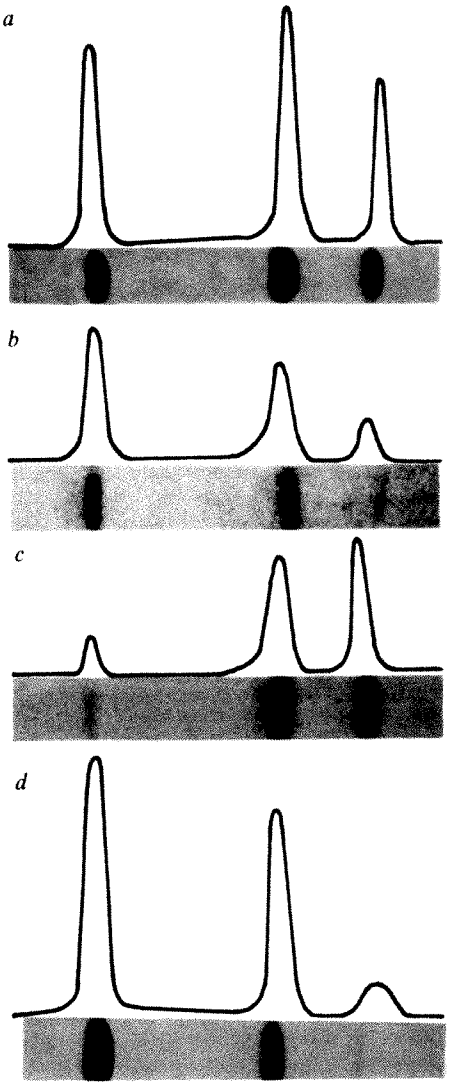

Fig. 1 SDS polyacrylamide gel electrophoresis of chicken pectoralis myosin. A separating gel 12.5% in acrylamide (*p*H 8.8) and a stacking gel 5% in acrylamide (*p*H 6.8) was used according to the method of Laemmli[24]. Gels were stained in 0.025% Coomassie brilliant blue (R250) dissolved in 45% methanol and 9% acetic acid, and destained by diffusion in 5% methanol and 7.5% acetic acid. Myosin loads are about 10 μg. Electrophoresis is from left to right (positive electrode) separating light chains into Al, DTNB and A2, respectively. *a*, Myosin control; *b*, Al myosin; and *c*, A2 myosin were prepared from chicken pectoralis myosin by using immunoadsorbents specific for A2 light chain and Al light chain, respectively (see refs 9 and 10); *d*, A1-exchanged myosin was prepared from chicken pectoralis myosin by addition of a tenfold molar excess of Al light chain in the presence of 4.7 M NH_4Cl, as described by Wagner and Weeds[15]. Excess light chain was removed by gel filtration on Sephacryl S-200 (Pharmacia). Gels were traced on a Joyce Lobel double-beam recording microdensitometer.

here, see refs 9 and 10), is contaminated by an even greater amount of heterologous light chain. If we assume that all the heterologous light chain in both the retained and unretained fractions is derived from a heterodimeric species, a maximum estimate of about 30% A1, A2 myosin is calculated[11]. However, any nonspecific binding of myosin to these immunoadsorbents would result in an overestimate of this figure. To establish with any confidence that a significant proportion of the myosin population consists of heterodimer, it was necessary to apply an independent approach to this problem.

The studies of Hoh *et al.* have provided such an alternative method by demonstrating that myosin solubilised in alkaline pyrophosphate buffer can be fractionated in low percentage polyacrylamide gels in the complete absence of denaturing agents[12]. In such a system, where myosin migrates according to its intrinsic mobility at that *p*H, chicken pectoralis myosin was found to separate into three bands. The material from each band was isolated by slicing the gel, and the light chain pattern was analysed by SDS polyacrylamide gel electrophoresis. It was found that the least mobile band contained only alkali 1 light chain, the most mobile band had only alkali 2 light chain, and the middle band contained both light chains. These results suggested that the band of intermediate mobility might be a light chain heterodimer[13,14]. However, it was not clear to what extent heavy chain heterogeneity might contribute to the band separation in this system, and it was possible that the band of intermediate mobility might arise from a mixture of light chain homodimers with different heavy chains. Our ability to prepare relatively pure homodimers of myosin allowed us to investigate directly whether the heavy chains contribute to the mobility of the isoenzymic species.

Figure 2 shows non-denaturing gels of native chicken pectoralis myosin and the homodimeric myosin molecules isolated by immunoadsorption as described above. The unfractionated myosin shows three bands (Fig. 2*a*), whereas A1 myosin (Fig. 2*b*) and A2 myosin (Fig. 2*c*) each migrate as a single band. Moreover, the A1 isoenzyme co-migrates with the slowest moving component in the control (Fig. 3*b*) and the A2 isoenzyme co-migrates with the fastest species (Fig. 3*c*). To demonstrate that the intermediate band was not generated by light chain exchange in the slightly alkaline conditions of electrophoresis, A1 and A2 myosin were mixed and applied to one gel. No intermediate band was observed (Fig. 2*d*). Similarly, no intermediate band was generated when the two isoenzymes were dialysed together for 24 h against pyrophosphate electrophoresis buffer. It thus seems reasonable to conclude that the band of intermediate mobility represents a light chain heterodimer, and is not simply the result of heavy chain heterogeneity or an experimental artefact.

These experiments do not rule out the possibility that the heavy chains contribute to the mobility of the individual myosin isoenzymes in this gel system. If, however, myosin mobility is solely a function of the alkali light chain, it should be possible to generate a single electrophoretic species from native pectoralis myosin by exchanging the native light chains with either alkali 1 or alkali 2. Such an exchange has been shown to occur in myosin subfragment-1 when it is incubated with an excess of alkali light

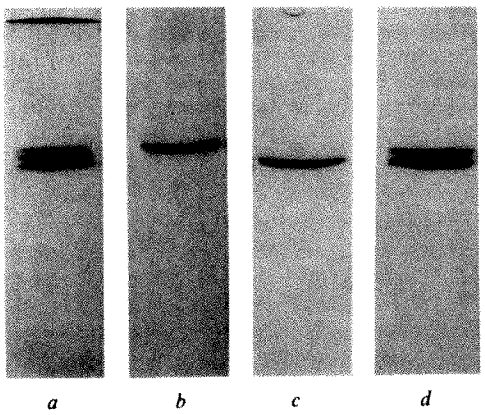

Fig. 2 Native myosin on non-denaturing gels. Polyacrylamide gels (4% acrylamide, 3% bisacrylamide) were prepared in the absence of denaturing agents in 40 mM pyrophosphate buffer (*p*H 8.7), 1 mM EDTA, 2 mM cysteine, 10% glycerol according to the method of Hoh[12]. Electrophoresis was carried out at a constant current of 6 mA per gel for 16 h with buffer recirculating at 60 ml per min. Gels were stained in 0.04% Coomassie brilliant blue (G250) dissolved in 3.5% perchloric acid[25], and destained by diffusion in 5% methanol and 7.5% acetic acid. Myosin loads range from 1 to 3 μg. Positive electrode was at the bottom of the gel. Samples were prepared as described in Fig. 1. *a*, Myosin control is resolved into A1 homodimer, A1,A2 heterodimer, and A2 homodimer (see text); *b*, A1 homodimer, and *c*, A2 homodimer each electrophorese as a single band, while the mixture (*d*) of both isoenzymes resolves into a two-band pattern lacking the middle band found in control myosin.

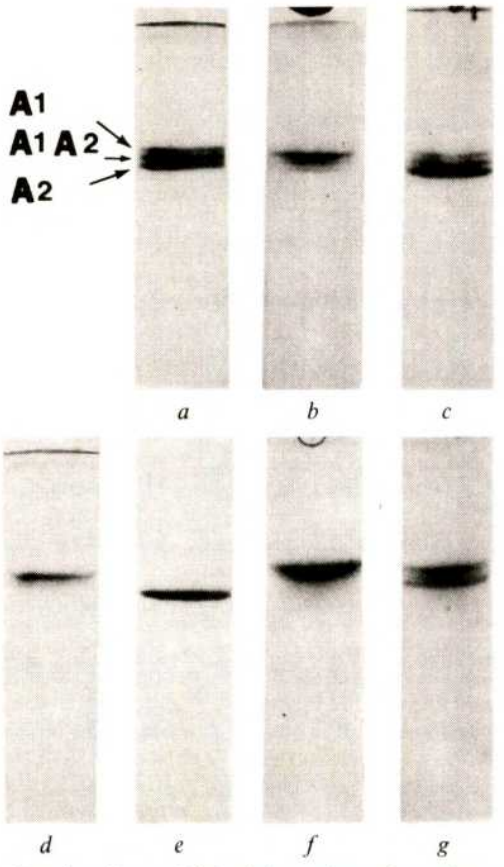

Fig. 3 Co-migrations and light chain-exchanged myosins on non-denaturing gels. Gels were run as previously described in Fig. 2. *a*, Control myosin shows three bands of approximately equal intensity; *b*, impure sample of myosin eluted in the void volume from an antibody affinity column specific for A2 light chain. There is an enrichment of the band of slowest mobility indicating that this contains A1 homodimer. *c*, Co-migration of control myosin and A2 myosin isolated from an antibody affinity column specific for A1 light chain. The enrichment of the band of fastest mobility shows that this represents A2 homodimer. Exchange of total (control) myosin with a tenfold molar excess of A1 light chain in 4.7 M NH_4Cl resulted in myosin of uniform mobility (*d*) which co-migrated with the single band from A1 myosin. A similar exchange was carried out using A2 myosin as the starting material (*e*) and adding an excess of A1 light chain in 4.7 M NH_4Cl. The exchanged myosin again ran as a single band (*f*) with a shift in mobility from that of the A2 myosin. Co-migration of A1-exchanged myosin and A2 myosin (*g*) resulted in two bands.

chain in the presence of 4.7 M NH_4Cl (ref. 15). By this means, a myosin species was generated from total chicken pectoralis myosin which contained only the alkali 1 light chain as determined by SDS gel electrophoresis (Fig. 1*d*). Electrophoresis of this myosin in the non-denaturing gel system shows primarily a slow-moving A1 myosin component, and trace amounts of the band of intermediate mobility (Fig. 3*d*). A similar result was obtained by exchanging A2 myosin homodimer produced by antibody affinity chromatography (Fig. 3*e*) with A1 light chain. A myosin species was generated whose mobility (Fig. 3*f*) was indistinguishable from that of naturally occurring A1 myosin homodimer.

The results presented here strongly suggest that in chicken pectoralis myosin the alkali light chain content is the principal determinant of mobility differences on non-denaturing polyacrylamide gels in pyrophosphate buffer. Therefore, the band of intermediate mobility must be an alkali light chain heterodimer, as suggested[13,14]. Chicken pectoralis myosin contains approximately equal amounts of alkali 1 and alkali 2 light chains[9,11]. If heavy chains associated randomly with light chains, one would predict that 50% of the myosin from this muscle would be heterodimeric for the light chains, 25% homodimeric for alkali 1 and 25% homodimeric for alkali 2. It is difficult to quantify the relative amounts of each component from densitometer traces of the gels shown in Fig. 2, as the resolution is poor, but we would estimate that there are approximately equal amounts of each species. A similar estimate has been made from pyrophosphate gel densitometry by Hoh[13] and d'Albis[14], and from quantification of material eluted from antibody affinity columns[11]. These values suggest, therefore, that light chain–heavy chain association is not strictly random.

Heavy chain heterogeneity has been observed in certain peptides isolated from rabbit myosin[16,17]; however, both of the heavy chain *N*-terminal peptides were found to be associated with each of the two subfragment-1 isoenzymes[18]. These findings, together with the observation that the actin-activated ATPase activity appears to depend on the type of alkali light chain present[15], argue against a specific interaction between the light and heavy chains of myosin. Nevertheless, these data cannot exclude the possibility that the alkali light chain homodimers may yet prove to differ from each other in heavy chain sequence, in spite of the absence of a contribution by the heavy chain to the electrophoretic mobility.

Precedents exist for both heavy chain homodimers and heterodimers. In chicken anterior latissimus dorsi myosin[13], and rat ventricular myosin[19], multiple band patterns on pyrophosphate gels have been demonstrated, in spite of the existence of only one light chain species analogous to the alkali light chains. In the case of rat ventricular myosin, peptide mapping of three isolated species showed the presence of two types of heavy chain homodimers as well as a heterodimeric myosin[19].

Homodimers of heavy chains have also been shown to occur in the nematode worm *Caenorhabditis elegans*[20]. Moreover, the synthesis of the two types of heavy chains is coordinated throughout larval development, and reflects the final accumulation of two populations of homodimeric molecules[21]. No heterodimers are detectable in the nematode. In contrast, the alkali 1 and alkali 2 light chains are not simultaneously synthesised during early development of vertebrate skeletal muscles and alkali 2 is largely absent in the prenatal stages of the rat[22] and chicken[23]. It is possible that uncoordinated synthesis of the alkali light chains persists in adult muscle cells, and this may account for the non-random distribution of light chains among the isoenzyme species. Alternatively, the affinity of the light chains for the heavy chains may be such that the formation of a heterodimer is less favoured than the more symmetrical molecules.

Although no single satisfactory explanation can be offered for the occurrence of light chain homodimers and heterodimers in fast skeletal myosin, the proof of their existence at least raises the intriguing question of their function in muscle contraction.

This study was supported by grants AM-17350 from the USPHS, PCM75-4790 from the NSF and a grant (S.L.) and fellowship (P.A.B.) from the Muscular Dystrophy Association.

Nucleotide sequence of a cDNA clone encoding human preproinsulin

Graeme I. Bell, William F. Swain, Raymond Pictet, Barbara Cordell, Howard M. Goodman & William J. Rutter

Department of Biochemistry and Biophysics, University of California, San Francisco, California 94143

Insulin consists of two polypeptide chains, A (21 amino acids) and B (30 amino acids), linked by disulphide bonds. Both chains are derived from one precursor, proinsulin, which includes a connecting peptide (C) between the A and B chains, and which is excised before the secretion of insulin from the pancreatic B cells[1]. The observation that the C-peptide varies between species, in contrast to the highly conserved A and B sequences[1-3], is consistent with the theory that it serves a purely structural function in insulin synthesis. During *in vitro* translation of insulin mRNA, a larger peptide containing about 25 additional residues at the N-terminal end (preproinsulin) is the primary product[4-7]. The prepeptide is cleaved to leave proinsulin during transport into the endoplasmic reticulum and is thought to direct this process specifically[8]. Using automated amino acid sequence analysis, the partial amino acid sequences of the prepeptide regions of bovine, rat, sea raven and anglerfish preproinsulin have been established[4,5,7]. The nucleotide sequences of the cloned cDNA and gene coding for rat insulin I have confirmed the amino acid sequence of rat proinsulin I, and have also predicted the sequence of the prepeptide[9-11]. Like the prepeptides of other secreted proteins, this prepeptide has a prominent hydrophobic region[12]. We report here the cloning of a cDNA prepared from human insulin mRNA and an analysis of the nucleotide sequence of the cloned molecule including the region coding for the prepeptide and portions of the 5'- and the 3'-untranslated regions of the molecule. We also compare the structure of the human molecule with the previously reported rat mRNA[9-11].

The mRNA used in these experiments was prepared from a human insulinoma by the guanidinium thiocyanate procedure[9]. Approximately 40 ng of double-stranded cDNA was prepared from 130 μg of unfractionated RNA and inserted into the *PstI* endonuclease site of the β-lactamase gene of pBR322 (ref. 13) using poly(dG)·poly(dC) homopolymeric extensions. The *Escherichia coli* strain X1776 was transformed with this DNA in P2 containment conditions according to the NIH Guidelines. This produced 525 tetracycline-resistant transformants. These were replica-plated and screened for insulin sequences by a modification of the colony hybridisation method of Grunstein and Hogness[14] using nick translated cloned rat preproinsulin I cDNA[9,11] as a probe. Since the amino acid sequence of rat and human insulins are quite similar (insulin, 92% homology and proinsulin, 83% homology), it was anticipated that the cloned rat cDNA should cross-hybridise with human insulin sequences in conditions of reduced stringency. After hybridisation as described[11], the filters were washed in a solution of 0.015 M sodium chloride, 0.0015 M sodium citrate, 0.1% SDS at 42 °C for 1 h. Autoradiography revealed that 2 out of the 525 colonies hybridised with the cloned rat preproinsulin I probe. Both colonies were ampicillin sensitive and contained plasmids that were approximately 250 and 500 base pairs larger than pBR322, the plasmid vector. The larger plasmid, pcHI-1, was analysed further.

The nucleotide sequence of the inserted cDNA fragment was determined by the procedure of Maxam and Gilbert[15]. The overall structure of the cDNA clone pcHI-1 and the sequencing strategy used are depicted in Fig. 1. The nucleotide sequence of both DNA strands was determined as indicated and the sequence of the remaining portions were done in duplicate; in all cases sufficient data were obtained to overlap the junctions of the fragments. The mRNA sequence derived from the cDNA

Fig. 2 Sequence of human preproinsulin mRNA. The sequence of the mRNA was deduced from that of the cDNA insert in pcHI-1. The predicted amino acid sequence is indicated above. The prepeptide region extends from the Met at position −24 to the Ala at position −1, the B-peptide from the Phe at position 1 to the Thr at position 30, the C-peptide from the Arg at position 31 to the Arg at position 65, and the A peptide from the Gly at position 66 to the Asn at 86. This cDNA insert also contains a poly(A) tract of approximately 45 bases extending from the 3'-terminal cytosine.

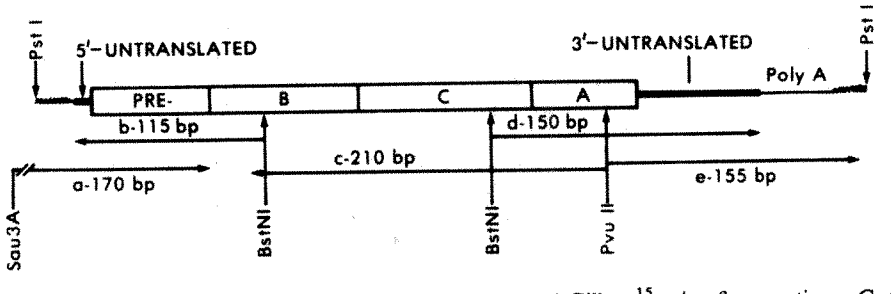

Fig. 1 Organisation and sequence strategy for the human preproinsulin cDNA insert in pcHI-1. The regions coding for preproinsulin are indicated by the open boxes. The wavy lines indicate the poly(dG)·poly(dC) tails of the cDNA insert (27 base pairs at the 5' end and 16 base pairs at the 3' end of the cDNA insert, respectively). Only the restriction sites used for sequencing are indicated. The 5'-end-labelled restriction fragments were derived from the intact plasmid and after the appropriate secondary endonuclease digestion used for sequencing by the procedure of Maxam and Gilbert[15] using five reactions: *G*, *G*+*A*, *A*>*C*, *T*+*C*, *C*. The number of bases determined from each sequencing experiment starting at the indicated restriction site is shown above the arrow. The *Sau*3A site is in the β-lactamase gene 58 base pairs from the *Pst*(I) site[13]. The size of human preproinsulin mRNA is approximately 550 base pairs as determined by hybridisation after electrophoresis in CH_3HgOH–agarose gels[16]. The cloned cDNA (cHI-1) is only 461 base pairs (including 45 A residues) and thus does not represent a complete copy of the mRNA.

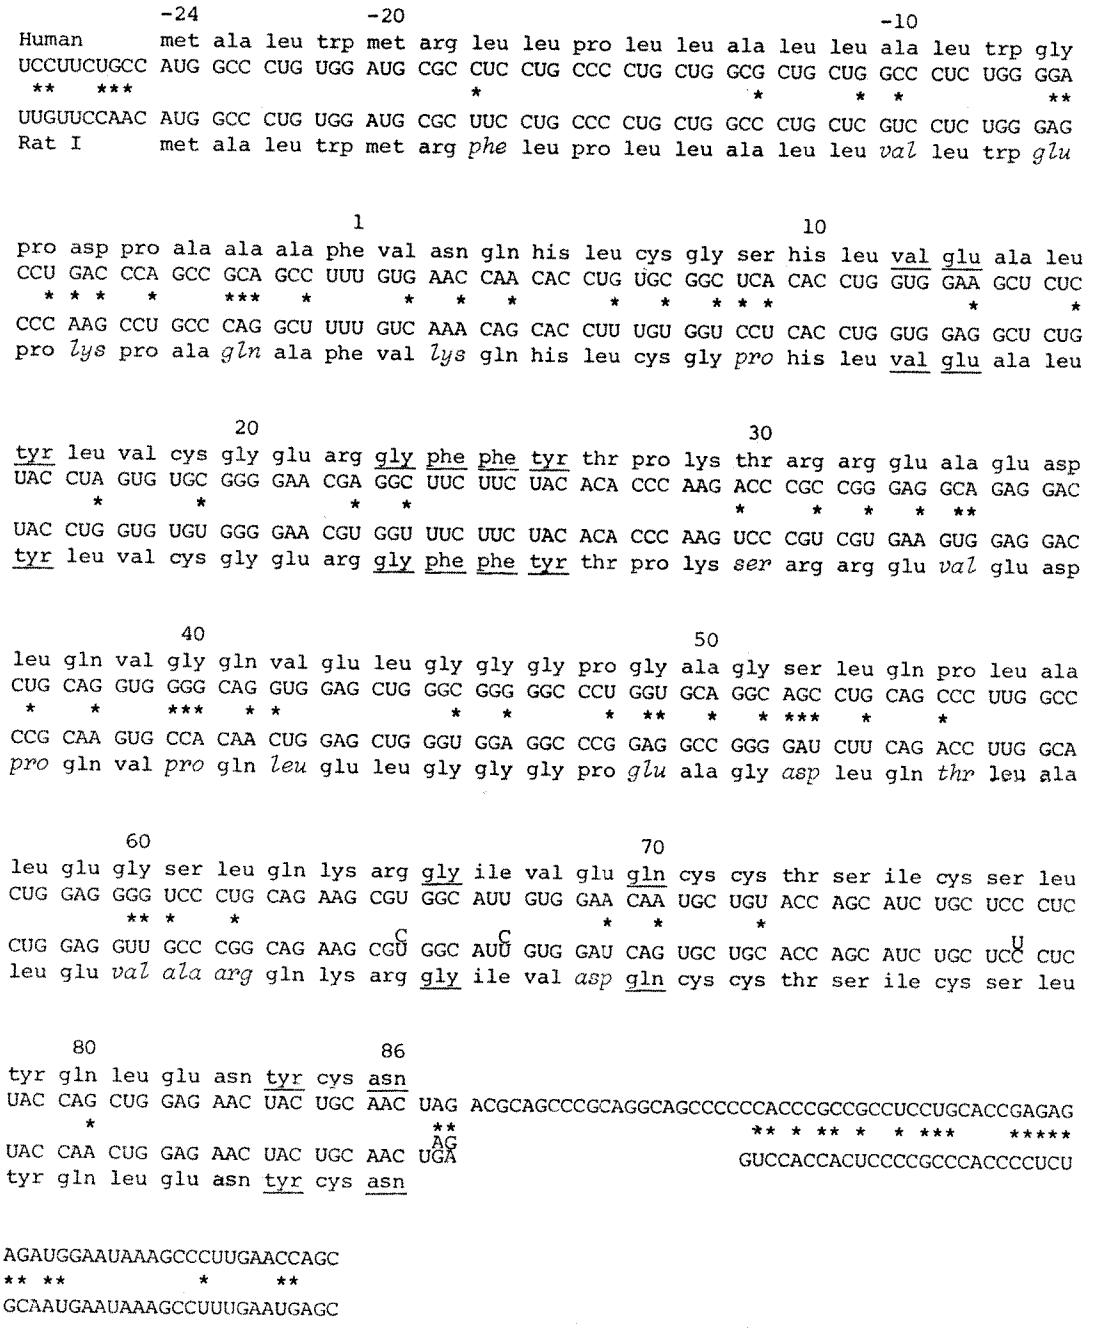

Fig. 3 Comparison of the sequence of human and rat preproinsulins. The sequence previously determined for rat preproinsulin I mRNA is indicated below that of human preproinsulin mRNA[9–11]. The nucleotide differences are indicated by asterisks. The amino acid sequence of the rat preproinsulin[9–11] is also compared with that of human preproinsulin. The differences in amino acids are indicated by italics. The amino acid residues believed to be involved in insulin receptor binding are underlined[17]. The 3′-untranslated region of rat insulin I has been shifted so as to emphasise its homology with human insulin mRNA in the 21-base pair region adjacent to the poly(A) attachment site. The previously cloned sequence of rat insulin II extends from the third base of the arginine codon at amino acid 62 to the G residue following the termination codon UAG. The nucleotide changes in the A chain of rat insulin II are indicated above the rat insulin I mRNA sequence; they result in three additional third-base changes; the termination codon for rat II is the same as for human insulin.

sequence, and the amino acid sequence predicted from one of the reading frames is presented in Fig. 2. The primary structure of human proinsulin determined in this manner agrees precisely with that obtained by previous amino acid sequencing experiments[2,3]. The predicted 24-amino acid sequence of the human prepeptide is similar to the sequence of rat insulin I and to the partial sequences obtained from bovine, sea raven and anglerfish prepeptides[4,5,7,9,11]. The nucleotide sequence of a small portion (10 bases) of the 5′-untranslated region and the complete sequence (76 bases) of the 3′-untranslated region (including the poly(A)attachment site) were also obtained.

Although the human preproinsulin cDNA is inserted into the β-lactamase gene of pBR322 in the correct orientation for expression, we would not expect a fused β-lactamase human preproinsulin polypeptide to be synthesised, since the two sequences are in different reading frames. We have examined the polypeptides produced in minicells by this plasmid (S. C. Rall and G.I.B., unpublished observations) and observed no polypeptides of the size expected for the fusion protein (approximately 300 amino acids). Instead, a molecule of approximately 220 amino acids was obtained. The nucleotide sequence predicts that translation of the β-lactamase–cDNA chimaeric mRNA should produce a fused protein which terminates at the UGA sequence at the junction of the second and third amino acids of the insulin B chain (Val·Asn, G*UG·AA*C; Fig. 2). This would generate a protein of the size observed.

The structure of insulin is highly conserved[1–3]. We have therefore compared the amino acid and nucleotide coding sequences, as well as the adjacent regions, of the mRNAs of human and rat insulin I (Fig. 3). The nucleotide sequence of the A chain of rat insulin II is also included[9]. This analysis is summarised in Table 1.

The high degree of amino acid sequence homology of the A and B chains extends to the nucleotide sequence. This is evident throughout the A chain and most of the B chain. However, in the B chain there are considerable nucleotide changes, largely in the third positions of the codons; thus there is more homology at the amino acid than at the nucleotide level. This contrasts with the situation in human and rat pregrowth hormones where the nucleotide homology is higher than the amino acid homologies[18–20]. A number of the amino acid residues are invariant in all insulin molecules and are believed to be involved in receptor

Table 1 Comparison of human and rat I and II preproinsulins and their mRNAs

Region	Homology (relative to human) Amino Acid Rat I	Amino Acid Rat II	Nucleotide Rat I	Nucleotide Rat II

3'-Untranslated	—	—	See text	

binding[17]; nevertheless there are nucleotide changes in these regions (Fig. 3).

Protein sequence studies indicate that the C-peptide is the most variable portion of proinsulin[1-3]. Although the length of the C-peptide varies in other species[1-3], it is the same in human and rat (35 amino acids; 71% homology). The nucleotide sequence homology is 72%. The prepeptide portions of human insulin and rat insulin I are more homologous than the C-peptides (79% amino acid; 81% nucleotide). Most of the differences that occur in the prepeptides are in the carboxyl terminal portion. Indeed the first 52 bases near the amino terminus seem to be as highly conserved as the B and A chains (48/52 bases = 96%), whereas the latter 20 bases are much less conserved (10/20 bases = 50%). This suggests that this portion of the prepeptide has a function. Examination of the first 24 amino acid residues of the molecules by the sequence-predictive method of Chou and Fasman[21] shows both α-helix and β-forming potential but the former is stronger; thus two helical segments (residues −24 to −17 and −16 to −8), connected by the helix-disrupting Pro (−16), are suggested. These are the regions with the highest degree of sequence conservation. A comparison of prepeptides of other secretory proteins shows a considerable variation in the amino acid sequences, however there is always a hydrophobic region in this type of structure[22]. The strong amino acid and nucleotide sequence conservation in this region of preproinsulin would suggest some element of specificity associated with this region of the molecule. It seems unlikely that the conserved structure is concerned with the cleavage reaction since preparations of signal peptidase[23] are able to cleave molecules with different prepeptide sequences. The relatively large area of homology in the prepeptide and the possible secondary structure are more suggestive of interaction with a receptor site. Receptor-mediated endocytosis has been implicated in the specific internalisation of a number of proteins from outside the cell (see ref. 24 for refs). A receptor-mediated mechanism may also be operative at the site of internalisation of the peptides in the endoplasmic reticulum. The lack of specificity seen in the sequestration of a number of secretory proteins in pancreatic microsomes[7,25,26] could be due to a reduced degree of specificity of the receptors in this system. Alternatively, the true specificity may not have been apparent because the rates of internalisation of proteins were not measured in these experiments.

Outside the region of the mRNA encoding the preproinsulin peptide the sequences of human and rat insulin I diverge rapidly. There is only 50% homology in the short region of the 5'-untranslated sequence in the clone. The clone probably lacks about 50 bases at the 5' end that are present in the mature mRNA. The 3'-untranslated region of human preproinsulin cDNA is 21 residues longer than the cognate region of rat preproinsulin I. Despite the difference in length and the sequence divergence of this region, there is a 21-nucleotide segment adjacent to the poly(A)attachment site that is highly conserved (18/21 = 86%). These 21 nucleotides include the AAUAAA sequence found in many eukaryotic mRNAs[27]. A similar conservation of a segment of the 3'-untranslated region including the AAUAAA sequence has been observed in the mRNAs of human and rabbit β-globin[28] and in the human and rat growth hormones[18-20], although the sequences conserved are different in each case. This suggests another gene-specific element of regulation which could operate at the level of transcription, translation or polyadenylation.

The cloned human insulin cDNA will be helpful in the analysis of human genomic DNA segments which encode insulin. Moreover, it should be useful for programming the expression of human insulin in alternative hosts, such as bacteria or yeast.

We thank Dr John Karam for providing the human insulinoma, Drs W. Wu and J. T. Yang for helpful discussions, Leslie Spector for assistance in preparing the manuscript, and Jeffrey Edman and Edmund Tischer for technical assistance. This work was supported by a grant from Eli Lilly Co. H.M.G. is an Investigator of the Howard Hughes Medical Institute.

N-terminal amino acid sequencing of prolamins from wheat and related species

Jean-Claude Autran*, Ellen J.-L. Lew, Charles C. Nimmo & Donald D. Kasarda

Food Proteins Research Unit, Western Regional Research Center, Agricultural Research, SEA, US Department of Agriculture, Berkeley, California 94710

The gliadins of common bread wheat (*Triticum aestivum* L.) make up the major storage protein fraction of grain endosperm and comprise a complex mixture of proteins with similar amino acid compositions and properties[1]. Two-dimensional methods of electrophoresis[2,3], in which separations are based mainly on net charge, separate gliadins of a single wheat variety into 30–46 components and there is considerable variation among the electrophoretic patterns of different wheat varieties[1]. The gliadins seem to be encoded by clusters of duplicated genes[2] and may constitute a multigene family[4]. The fact that several purified gliadin components have closely similar N-terminal amino acid sequences[5,6] led us to consider the possibility that, despite the complexity of the mixture, gliadins have sufficient homology in their N-terminal sequences to allow estimation of the homology by sequencing the unfractionated mixture. Here, we provide

* Permanent address: Institut National de la Recherche Agronomique, Laboratoire de Technologie des Blés Durs et du Riz, 34060 Montpellier, France.

evidence for two major groups of gliadins in wheat based on N-terminal sequencing, show that similar groups of prolamins (a general term for equivalent proteins in other species) are found in related species of *Triticum* and *Aegilops* that may have contributed genomes to polyploid wheats with *ABD* genome composition, and show that only one of these groups is found in rye (*Secale cereale* L.).

Wheat and other grain samples used are listed in Table 1. The prolamins of common wheat, *Triticum monococcum*, and rye were prepared from endosperm only (flour) whereas those of other samples, of which we had only small amounts, were prepared from de-germed grain that was ground in a Wiley mill. Prolamins were prepared according to the procedure of Charbonnier[7] except that the final product was dissolved in 0.01 M acetic acid or 60% ethanol-water and dialysed thoroughly against distilled water. The small amount of precipitate that formed (5% or less of the amount dissolved) was removed by centrifugation and the clear supernatant was freeze-dried. Rye prolamins were less soluble in water—about two-thirds of the preparation precipitated—and both the precipitate and the supernatant were freeze-dried separately for use in sequencing. Yields of prolamins ranged from 3 to 8% of starting material. Electrophoretic patterns of typical preparations, which illustrate the complexity of the mixtures, are shown in Fig. 1.

Automatic sequencing[8] was carried out on a Beckman sequencer model 890B with DMAA peptide program 111374. Eight cycles were considered sufficient for our purposes. (One sample, *T. monococcum*, was sequenced only through six cycles.) Residue identification was by gas chromatography (GC) according to the procedure of Pisano *et al.*[9]. In all cases, only a few phenylthiohydantoin (PTH) amino acids (sometimes only one) were identified at each cycle of the Edman degradation and recoveries were sufficient to account for 70–80% of the protein sample when moisture contents (10%), probable sequencer yields (65% assumed[10]) and prolamin molecular weights (36,000 assumed[1]) were taken into account. Typical results are given in Table 2.

The major PTH amino acids at each cycle usually corresponded to the sequence Val-(Arg?)-Val-Pro-Val-Pro-Gln-Leu- for all species of *Triticum* and *Aegilops* except for the wheat variety 'Justin' and an accession of *Triticum urartu* (G-1876), where it was the minor sequence. This sequence corresponds to that of α-gliadins[5,6]; we shall refer to it as the α-type sequence, although Bietz *et al.*[6] found this sequence also in a β-gliadin and a γ-gliadin (γ_1-gliadin). Arg and His were not determined by our GC method. We assume Arg to be an important amino acid at position 2 by analogy with the α-gliadin sequence[5,6] and identified it at cycle 2 in two samples by liquid chromatography.

A second sequence corresponding to Asn-(Met/Ile)-Gln-Val-(Val/Asp)-Pro-Gln-Gly- was present in all the samples of *Triticum* and *Aegilops*. This sequence is similar to the γ_2- and γ_3-gliadin sequences described by Bietz *et al.*[6] (Table 2); we shall refer to it as the γ-type sequence. It was the minor sequence in most samples except for 'Justin' and *T. urartu* G-1876, where it was present in amounts about equal to (or greater than) the amount of α-type sequence. *T. urartu* G-1876, however, had only a trace amount of Asn at cycle 1; the major amino acid was Val (40 nm) followed by Ala (17 nm). We usually found both Met and Ile at cycle 2, but our sample of *T. monococcum* showed only Ile at cycle 2 whereas our sample of *Aegilops speltoides* showed only Met at cycle 2.

The α-, β-, γ- and ω-regions correspond to the usual assignments of electrophoretic mobilities for gliadin patterns of common wheats[1].

On the basis of N-terminal sequences, our results indicate two major homologous groups of prolamins in the species of *Triticum* and *Aegilops* we examined. Because these species were fairly representative of the two genera, this may be true in general. Based on sequencer yields, we estimate that these two groups account for about 70–80% of our prolamin preparations. A fairly clear difference between the α-type and γ-type sequences occurs at residue 4, where Pro is found in the former and Val or Gln in the latter (Table 2). Pro and Val were the only two amino acids we identified at cycle 4 for all species of *Triticum* and *Aegilops* with the exception of one accession of *T. urartu* (G-1876), which also had a small amount of Leu at this position. The ratio of Pro to Val at cycle 4 may provide a measure of the relative amounts of the two groups of proteins in a sample. These ratios are listed in Table 1, and range from 0.8 to 2.2. They sometimes differed for different varieties or samples of the same species. For example, the two hexaploid bread wheats, 'Scout 66' and 'Justin', had ratios of 1.6 and 0.8, respectively. The large amount of α-type sequence in 'Scout 66' is consistent with the large amounts of α-gliadins in this variety[11]. In contrast, 'Justin' is low in α-gliadins[11]. The presence of both α-type and γ-type prolamins in species of *Triticum* and *Aegilops* indicates the close relationship of these genera, and supports the proposal of Morris and Sears[12] that *Aegilops* be incorporated into the genus *Triticum*.

Both the water-soluble and the water-insoluble prolamins from 'Frontier' rye differed from those of the other species examined in lacking the α-type sequence, although we might not have detected a sequence corresponding to about 10% or less of the mixture. The sequences of these rye prolamin preparations were not identical to one another but both were fairly close to the γ-type found in species of *Triticum*[6] and *Aegilops*. Although minor amino acids were identified at most cycles of the rye prolamin degradation, these did not correspond to known gliadin sequences. The electrophoretic patterns of rye prolamins at *p*H 3 vary somewhat according to variety[13], but they do not show a significant amount of staining in the region of mobility corresponding to α-gliadins[13]. As we have noted above, however, the α-type of sequence has been found for proteins with other electrophoretic mobilities[6], so the agreement between our sequencing results and the electrophoretic patterns may not be essential.

Table 2 Recovery of PTH amino acids for different species (nmol)

γ_3-gliadin[6]	Asn Pro	Met	Gly Gln	Val Gln	Asp Val	Pro Gln	Trp Gln	Gly

Recoveries are reported on a basis of 10-mg samples.
* Arg is likely to be an important residue at position 2, but Arg and His were not determined by our GC method: in addition, the quantitation of Asn and Gln was less accurate than that of the other amino acids.

The presence of only the γ-type sequence in our sample of rye prolamin may indicate that rye is closer evolutionarily than *Triticum* and *Aegilops* to the common ancestor that gave rise to the sub-tribe Triticinae[14], which includes both wheat and rye, within the family Gramineae. Differentiation may have included the development and amplification of genes coding for α-type prolamins in *Triticum* and *Aegilops*. This speculation is based on results for only one variety of rye; further work on additional varieties and types is needed to allow its generalisation to the species as a whole.

The great homology among the mixtures of prolamins we have studied enables considerable sequencing information to be obtained from them without isolating single protein components. This has also been demonstrated[15] for the zein proteins, the prolamins of maize (*Zea mays*). This homology is notable in consideration of the complexity of the mixtures. The prolamins of species of *Triticum* and *Aegilops* consist of many components that may differ in molecular weight as well as in charge; prolamin preparations from various species of these genera were resolved into at least four (usually more) bands by SDS electrophoresis (E. C. Cole, J. G. Fullington and D.D.K., unpublished results). Small differences in amino acid composition have been found for gliadin components that differ in electrophoretic mobility (aluminium lactate buffer, *p*H 3.2)[1], and gliadin proteins corresponding to particular bands of the *p*H 3.2 patterns exhibited simple inheritance in crosses between wheat varieties that differed in their electrophoretic patterns[2]. Regardless of whether the complexity of gliadins and other prolamin mixtures results from multiple genes, post-translational modifications or some other mechanism, the high degree of homology we found for their N-terminal sequences suggests that this region has some important function and thus tends to be conserved.

We thank B. L. Johnson, J. G. Waines, P. Mattern, V. A. Johnson, C. O. Qualset, J. Dvorak, B. L. Jones, and R. Bieter for providing us with grain samples. J.-C.A. is a Visiting Scientist. Reference to a company and/or product name by the Department is only for information and does not imply approval or recommendation to the exclusion of others that may also be suitable.

Proposed structure of the anthramycin–DNA adduct

Laurence H. Hurley & Ruby Petrusek
College of Pharmacy, University of Kentucky, Lexington, Kentucky 40506

Anthramycin, an antitumour antibiotic produced by *Streptomyces refuineus*[1], belongs to the pyrrolo(1,4)benzodiazepine antibiotic group[2]. Antibiotics within this group are potent inhibitors of nucleic acid synthesis because of their ability to form a labile covalent adduct with DNA[2–6]. The reaction of anthramycin with DNA is unusual in that the rate of adduct formation is slow[2,4,5], shows an absolute specificity for deoxyguanosine in a double-stranded template[4], and is only stable as long as the secondary structure of DNA is retained[6]. Experiments using confluent non-dividing human cell lines have demonstrated that while repair-proficient cells are able to remove up to 84% of the adduct within 72 h, xeroderma pigmentosum cells in complementation group A were only able to remove 49% during the same incubation period[10]. We propose here a Corey, Pauling and Koltun (CPK) molecular model for the anthramycin–DNA adduct in which anthramycin is attached through the 2-amino group of guanine and lies hidden in the narrow groove. Experimental data supporting this model are provided. The model is based on information about the probable covalent binding sites on anthramycin and guanine together with the known crystal structure of anthramyin[7].

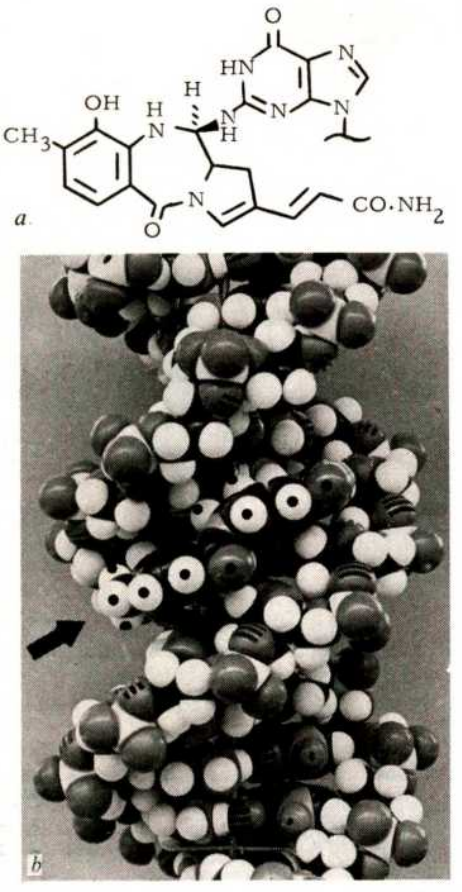

Fig. 1 Structure (*a*) and CPK space filling model (*b*) of the anthramycin–DNA adduct in which anthramycin is attached through C-11 to the N-2 group of guanine.

Structure activity relationships for anthramycin and related compounds provide compelling evidence that the carbinolamine is the reactive group on anthramycin[2,4,5,14]. X-ray diffraction studies on crystals of anthramycin show that the molecule is twisted 40 to 50° from one end to the other along the long axis and thus might fit into one of the grooves of DNA[7]. From studies using synthetic polydeoxynucleotides, guanine is apparently the reactive base on DNA[4]. Of the possible positions for alkylation by anthramycin, N-7, N-3, and C-8 have been eliminated because of: (1) the results of an alkylation assay using [8-^{3}H]guanine-labelled DNA; (2) absence of strand breakage *in vitro* using SV40 DNA; and (3) the lack of increased susceptibility to depurination of the anthramycin modified [8-^{3}H]guanine-labelled DNA[8]. The unreactivity of polydI:dC towards anthramycin, while polydG:dC binds the drug at least as well as native DNA[4], strongly suggests that the N-2 position on guanine is directly involved in adduct formation. Model building using a CPK molecular model of DNA and anthramycin in the published crystal conformation demonstrated quite dramatically that while O-6 was inaccessible to adduct formation without bond cleavage or serious distortion of DNA, adduct formation through N-2 of guanine produced a remarkably snug fit. The anthramycin molecule which is attached through C-11 to N-2 of guanine by an aminal linkage fits within the narrow groove of DNA (Fig. 1). The predictions which result from this model and the experimental data substantiating our model are presented below.

At saturation binding in DNA, where 25% of the bases are guanine and the drug molecule covers five base pairs, the maximum binding ratio would be 1:10. However, as the distribution of guanine residues is not uniform the frequency will be somewhat lower, and the experimentally determined ratio of 1:12. 8 (ref. 2) is probably close to the theoretical value.

Binding of anthramycin should not cause unwinding or lengthening of DNA as the drug binds in a non-intercalative manner within the narrow groove. Viscosity and sedimentation measurements have shown that the DNA molecule is stiffened but not lengthened on anthramycin binding[9]. Experiments using SV40 DNA, predominantly in the supercoiled form, have shown no unwinding at an antibiotic to base ratio of 1:300.

Our model shows that the angle of the chromophore of anthramycin is inclined at 45° relative to the helix axis. This compared very well with the reported value of 36° as determined by electric dichromism measurement[9].

The drug is held to DNA by an animal linkage plus secondary stabilising forces, chiefly between the phenolic group at C-9 of anthramycin and the 2-keto group of cytosine in the same base pair. As the animal linkage is inherently unstable, conditions which remove the secondary stabilising interaction should lead to release of anthramycin from the adduct. The predictions are mimicked in practice as denaturation of the DNA by acid *p*H (ref. 5), heat and enzymatic degradation[6], lead to rapid release of free drug from the DNA adduct.

In the proposed model, anthramycin fits into the narrow groove of DNA without distortion or protrusion outside of the helix. To probe the modified DNA for distortion or protrusion of the adduct outside the helix, S_1 nuclease digestions and benzoylated napthalated DEAE (BND)-cellulose chromatography on the adducts were carried out. The results (Fig. 2, Table 1) show that S_1 nuclease was unable to reveal any regions of distortion in the drug-modified DNA and, in fact, release of nucleotides was inhibited with increasing amounts of drug modification. The BND-cellulose chromatography results demonstrated lack of single strandedness of DNA induced by anthramycin as well as binding of anthramycin to the resin which would be anticipated if the drug protruded outside the DNA helix.

The orientation of anthramycin in the narrow groove allows interactions between the phenolic group at C-9 of anthramycin and the 2-keto group of cytosine. Titration[4] and CD measurements[9] have shown that in the adduct, the phenolic hydroxy proton is no longer available for titration, which is in accord with

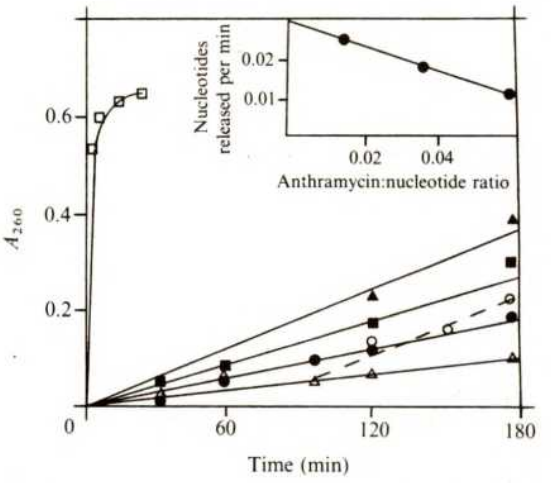

Fig. 2 Time course hydrolysis of calf thymus DNA during digestion with S_1 nuclease in the presence of increasing amounts of bound anthramycin. Assays were carried out essentially as described by Vogt[13]. Calf thymus DNA in 0.1 M SSC was diluted into reaction buffer to produce a final concentration of 0.03M Na acetate *p*H 4.6, 0.025 M NaCl and 0.005 M $ZnSO_4$. The reactions were carried out at 37 °C. Aliquots were removed at various times and transferred into 0.4 ml cold 10% perchloric acid. The samples were centrifuged (10,000*g* for 15 min) and the A_{260} of the supernatant was measured to determine the release of nucleotides by the enzyme. The anthramycin:nucleotide ratio was 0(▲); 0.015 (■); 0.037 (●); 0.063 (△); DNA concentration 150 μg ml^{-1}, enzyme concentration 2×10^3 U ml^{-1}. Heat denatured DNA (□). At 90 min unmodified calf thymus DNA was added to an enzyme incubation containing drug-modified calf thymus DNA (○). Inset, dependence of the nucleotides released per min against anthramycin:nucleotide ratio.

Table 1 Estimation of the single strandedness and protrusion of anthramycin molecule external to DNA found in the anthramycin-DNA adduct using BND-cellulose chromatography

1:1134	4†	12†
1:144	3	12
1:34	2	10

Chromatography on BND-cellulose in which step elution using 1 M NET (1.0 M NaCl–10^{-4} M, EDTA-0.01 M Tris HCl, *p*H 7.5) eluate and a 50:50 1 M NET: formamide mixture can be used to estimate the double-stranded DNA (eluted with 1 M NET) against DNA containing single-stranded regions[11] or protruding aromatic moieties[12] in a sample of DNA. To obtain DNA without single-stranded breaks or regions, calf thymus DNA (Sigma) was pre-chromatographed on BND-cellulose. The 1 M NET eluate (double-stranded DNA) was dialysed against 0.1 SSC, bound to varying concentrations of [15-^{3}H]anthramycin (4.0 μCi μmol^{-1})[5], and again dialysed against 0.1 SSC to remove any unbound antibiotic. Control DNA was also dialysed. The DNA–anthramycin adduct (140–220 μg DNA) was then applied to BND-cellulose columns (1 ml column volume) and eluted successively with 10 ml of 0.3 M NET (0.3 M NaCl–10^{-4}, EDTA-0.01 M Tris HCl, *p*H 7.5), 10 ml of 1.0 M NET and 10 ml of 50% formamide in 1.0 M NET. 2.0 ml fractions were collected. Radioactivity was determined by adding 1.0-ml aliquots to 10 ml of Aquasol (NEN) and DNA by optical density measurement at 260 nm. Optical density measurements of the formamide: 1.0 M NET fractions were corrected for background absorption using a control column without adding DNA.

* The % adherence represents the fraction of absorbance at 260 nm and the fraction of radioactivity eluted with 50% formamide in 1 M NET out of the total amounts eluted with 1 M NET and 50% formamide in 1 M NET.

† The larger values for the apparent percentage adherence found in the radioactivity determinations are most probably due to a small amount of release of drug from the DNA during manipulation before and during chromatography.

our model in which hydrogen bonding between the phenolic group and the 2-keto of cytosine is possible. Our model also accounts for the tighter binding of sibiromycin to DNA than anthramycin as the amino sugar attached at C-7 of sibiromycin binds externally to the deoxyribsose phosphate backbone of the helix.

As the anthramycin–DNA adduct is well concealed within the narrow groove of DNA it might be anticipated that excision repair would be a slow process due to the lack of distortion or protrusion which would normally lead to ready recognition of the drug-modified DNA. In practice the drug is only excised relatively slowly over a 48-h period in confluent normal non-dividing human cells[10].

This proposed model for the anthramycin-DNA adduct explains fully both the *in vitro* and *in vivo* data so far obtained. The proposed type of binding to DNA in which the drug molecule is attached by a labile covalent adduct and resides inside the narrow groove seems to be unique to the pyrrolo(1,4)benzodiazepine antibiotics and perhaps explains some of the unusual biological effects of this group of agents. Further experiments using stable isotopically labelled anthramycin and synthetic polydeoxynucleotides should vigorously establish the points of covalent linkage.

We thank Dr Gary Anderson for advice and discussion, Dr Arthur Broom for construction and photographs of the CPK model of the drug adduct, S. Estes, D. Brewer and L. Buch for technical assistance, and the NCI for financial support (CA-17047).

Energy uptake in the first step of visual excitation

Alan Cooper

Department of Chemistry, Glasgow University, Glasgow, UK

Perception of light by the retina starts with the absorption of a photon by 11-*cis* retinal, which is covalently incorporated into the membrane-bound protein, rhodopsin[1]. The initial result of photon capture is the very rapid formation of a red-shifted species, bathorhodopsin[2–4] (also known as prelumirhodopsin), which is (meta-)stable at liquid nitrogen temperature but which decomposes at higher temperatures, in the dark, through a series of intermediate stages, resulting in the release of all-*trans* retinal from the apoprotein, opsin. Bathorhodopsin formation is the only photochemical step in the overall reaction and, therefore, merits investigation. Several models for the process have been proposed, and have been critically reviewed[5–8], although no consensus yet exists as to the nature or mechanism of formation of the batho intermediate. I report here on the first direct measurement of photon energy uptake during bathorhodopsin formation from bovine rhodopsin, and on its possible significance.

We have previously described in detail the technique of photocalorimetry[9] and its application to the determination of the energetics of the later stages in the photolysis of rhodopsin[9] and isorhodopsin[10]. The present study required the construction of a calorimeter suitable for use at very low temperatures (Fig. 1). This instrument is based on the isothermal heat conduction principle[11] and allows direct measurement of the total heat energy dissipated in a sample during monochromatic illumination. In the differential mode, the energy of the exciting light may be subtracted automatically, yielding directly the photochemically-induced uptake or release of energy in the sample. The present instrument has a sensitivity of about 0.1 μV μW^{-1} at 298 K, falling to about 0.02 μV μW^{-1} at 77 K due to the intrinsic thermal properties of the thermoelectric sensors. Bovine rod outer segments, prepared by standard sucrose gradient techniques[12] were suspended in either aqueous or neutral detergent (Ammonyx-LO)–glycerol mixtures and irradiated in the photocalorimeter (in liquid nitrogen) at 450 or 485 nm. Samples enriched in bathorhodopsin were generated *in situ* by irradiation at 485 nm and photoreversal was induced by irradiation at 560 nm (ref. 3). Extents of photoreaction were determined by the change in absorbance at 500 nm ($\varepsilon = 41{,}000$) of samples warmed to room temperature and dispersed in 2% (w/v) cetyltrimethylammonium bromide (CTAB), 0.1 M phosphate *p*H 7.0, 10 mM hydroxylamine. Typically, 10–20 nmol of rhodopsin were bleached in any one experiment.

Illumination of rhodopsin at 77 K gives rise to an unambiguous uptake of energy in parallel with bathorhodopsin formation (Fig. 2*a*), and this stored energy is released (Fig. 2*b*) on photoreversal to rhodopsin. (Formation of some 9-*cis* pigment, isorhodopsin, is to be expected during photoreversal[3] but, as its energy is only about 5 kcal mol^{-1} higher than rhodopsin[10] this has no major effect on the observations.) No net heat effects were observed in control experiments with totally bleached rhodopsin samples. The combination of a series of

0028-0836/79/480531—03$01.00

© 1979 Macmillan Journals Ltd

determinations yields:

$$\text{rhodopsin} \xrightarrow[77\,K]{h\nu} \text{bathorhodopsin}$$

$$\Delta H = +34.7\ (\pm 2.2)\quad \text{kcal mol}^{-1}$$

Within experimental error identical results are obtained for irradiation at two different wavelengths (450 and 485 nm), and for both detergent-solubilised rhodopsin and outer segment suspensions. The latter observation suggests that, at this level, the precise molecular environment of the rhodopsin molecule has little influence on the energetics of the primary process.

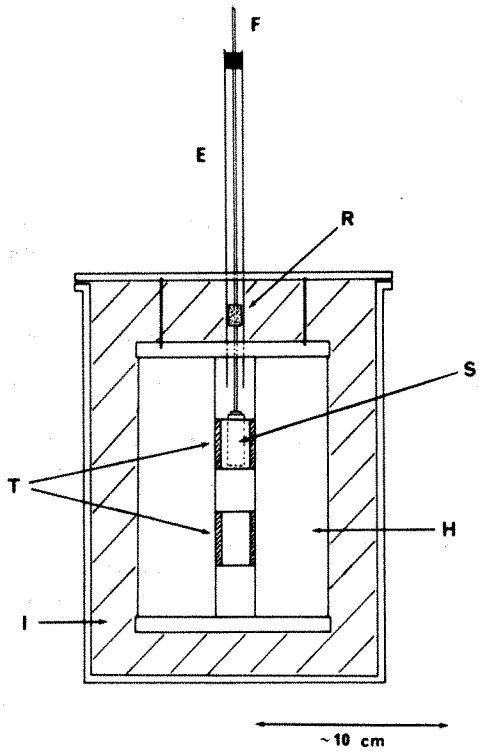

Fig. 1 Low temperature photocalorimeter. The sample (up to 2.5 ml) is enclosed in a cylindrical gold-plated, stainless-steel cell (S) fitted with flexible fibre-optics light guides (F) for illumination. A coaxial thermal radiation shield (R) minimises thermal leakage down the sample entry tube (E). The thermoelectric sensors (T) are solid-state Peltier cooling devices (Borg-Warner 950-71), the output voltage of which is proportioned to the rate of heat flow between the sample block and the heat sink (H). The second (lower) set of sensors, with dummy sample block, is connected in opposition to reduce the effects of thermal fluctuations in the heat sink. A second sample cell (not shown) is mounted behind and parallel to the first, such that differential measurements may be made. Small heater coils are permanently mounted in the sample block for electrical calibration. Insulation (I) is with expanded polystyrene foam. The entire unit was suspended in a liquid nitrogen Dewar vessel, with the upper end of E contained in a N_2-flushed dry box to eliminate condensation during sample loading and removal. Light source was a 150 W xenon arc and grating monochromator, with appropriate optics for coupling to the fibre-optics light guides. Sensor voltages were monitored with a Keithley 150B μV ammeter, averaged and integrated over 1-min intervals, and presented digitally. The equipment was installed in a temperature-controlled darkroom.

Thus, the ground-state energy of bathorhodopsin is about 35 kcal (145 kJ, 1.50 eV) higher than rhodopsin. It had been anticipated that the primary reaction should be endothermic, as the thermal instability of bathorhodopsin implies an elevated thermodynamic free energy[5,9,13], and entropy contributions are not expected to be significant at low temperatures[7]. The magnitude of the energy storage is, however, much higher than theoretical models have suggested[14,15], amounting to more than 60% of the absorbed photon energy at the 500-nm absorbance maximum of bovine rhodopsin. It is also significantly higher than the measured barrier of ~25 kcal for thermal isomerisation about the conjugated double bonds of free retinal[16]. If, as seems most probable on evidence so far[7], bathorhodopsin formation involves at least partial rotation about the retinal 11–12 double bond, then interactions in the retinyl binding site of the protein have a dominating influence on the process, forcing dramatic changes in the conformational potential energy map of the chromophore.

It has been argued that rhodopsin and bathorhodopsin share a common, barrierless, excited-state energy surface[5–7]. Knowing the ground-state energy of bathorhodopsin, together with spectroscopic and other data, it is possible to begin to reconstruct a more quantitative picture of the potential energy surfaces for the photoreaction (Fig. 3). The interesting possibility then arises that the energy surfaces for the ground and excited states might actually overlap in some region of reaction-space. This conjecture arises from the following considerations: (1) the energy of bathorhodopsin is high (35 kcal above rhodopsin); (2) thermal decay of bathorhodopsin to the next intermediate, lumirhodopsin, involves an activation barrier of about 10 kcal (ref. 17) and, as thermal regeneration of rhodopsin from bathorhodopsin has not been observed, this suggests a ground-state barrier in excess of 45 kcal between rhodopsin and bathorhodopsin; and (3) the excited-state surface must have a minimum below 57 kcal (≡500 nm) in order to guide the system towards bathorhodopsin[5]. A hint to the possible intersection or overlap of the energy surfaces comes from the classic experiments of St George[18], which showed that at long wavelengths rhodopsin photolysis becomes temperature dependent, and that

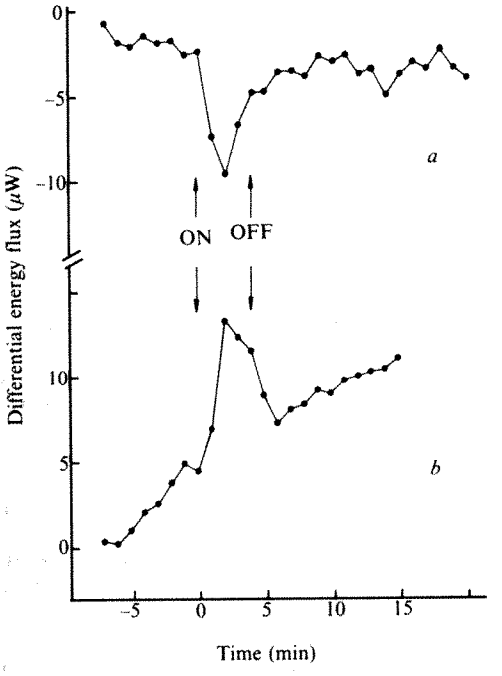

Fig. 2 Differential thermal response on irradiation of rhodopsin and bathorhodopsin in the photocalorimeter at 77 K. The sample consists of bovine rod outer segments dispersed in a mixture of glycerol (67%), Ammonyx-LO (2.5%), 10 mM phosphate buffer pH 7.0. *a*, Rhodopsin → bathorhodopsin: 4 min irradiation at 485 nm resulting in a net heat uptake. About 15 nmol of rhodopsin (~20% of the sample) were bleached in this experiment. *b*, Bathorhodopsin → rhodopsin: the above sample was irradiated continuously at 485 nm to produce a steady-state mixture of bathorhodopsin, rhodopsin and isorhodopsin. Subsequent 4 min irradiation at 560 nm (shown) demonstrates the exothermic photoreversal of bathorhodopsin to rhodopsin. (Baseline drift in these experiments is caused by slow temperature variation in the calorimeter, estimated to be less than 5×10^{-6} °C min^{-1}).

thermal and electromagnetic energy can combine to bleach rhodopsin. The critical wavelength for onset of this phenomenon is 590 nm, suggesting a possible intersection of the energy surfaces at about 48 kcal. Figure 3 has been drawn with this energy in mind.

Given this topology, the response of rhodopsin to photon absorption might be as follows: vertical (Franck–Condon) excitation to a high vibrational level of the excited state followed by rapid vibrational relaxtion to lower levels and efficient crossover to isoenergetic states of the ground-state surface in the intersecting region. Further relaxation to the ground-state of bathorhodopsin, or back to rhodopsin, would depend on the dynamics of the situation but, experimentally, bathorhodopsin is favoured in the ratio of about 2:1 (refs 5, 6).

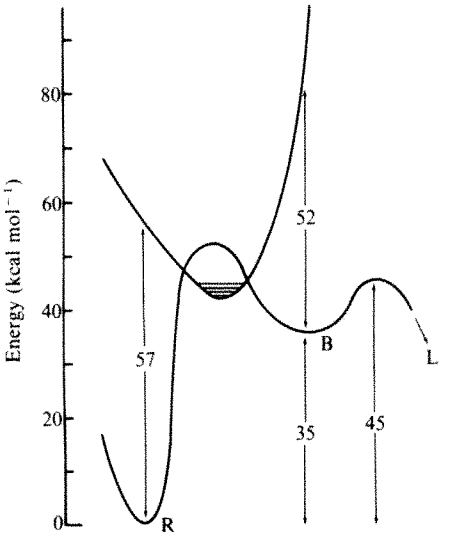

Fig. 3 Two dimensional projection of the possible ground- and excited-state potential energy surfaces for the primary step in rhodopsin photolysis. The ground-state energy of bathorhodopsin (B) with respect to rhodopsin (R) is from direct measurement. Vertical excitation energies to the electronically excited state are from absorbance maxima (500 and 548 nm for R and B, respectively). The B → L (lumirhodopsin) barrier is from kinetic data[17], and suggests a lower limit to the R → B barrier in the ground state. The possible overlap (in projection) of the two surfaces is, probably, exaggerated for clarity. The hatched region indicates possible trapping in lower vibrational levels of the excited-state energy minimum at low temperatures. The nature of the reaction coordinate needs further clarification, but probably includes the retinal 11–12 torsion angle[5–7] as well as other chromophore and protein parameters.

One interesting consequence of energy surface overlap is that at very low temperatures excited molecules might get trapped in vibrational states of lower energy than the ground state of the same conformation (Fig. 3), leading to an energy barrier and a temperature dependence in the rate of bathorhodopsin formation from the excited state, perhaps as observed in picosecond studies[19]. However, even at the very lowest temperatures, some crossing over to the ground-state surface might be expected before complete thermal relaxation after excitation, and non-Arrhenius kinetic behaviour might be seen, possibly without the need to invoke quantum mechanical tunnelling processes[19]. Deuterium isotope effects[19] would arise in this situation from changes in the vibrational energy levels of modes involving exchangeable hydrogens on the protein and chromophore.

Although we have yet to understand the process in molecular terms, it seems clear that protein–chromophore interactions in rhodopsin have evolved to provide a smooth and efficient pathway for the inital photochemical step in photoreception, whilst maintaining sufficient stored energy to drive the subsequent processes which give rise to the visual stimulus.

I thank Mrs M. Nutley for technical assistance, and various colleagues for helpful discussions. Financial support for this work was provided by the SRC.

Evidence for nitrogen fixation (*nif*) genes on indigenous *Rhizobium* plasmids

M. P. Nuti*§, A. A. Lepidi*, R. K. Prakash†, R. A. Schilperoort† & F. C. Cannon‡

The distinguishing characteristic of bacteria that belong to the genus *Rhizobium* is their ability to induce nodules and fix nitrogen in the roots of leguminous plants—hence their importance in agriculture. The demonstration of nitrogen-fixation by rhizobia in the absence of host plant material showed that the genes for nitrogenase synthesis and function reside in the bacterium[1–3]. The presence of large plasmids (molecular weight (MW) 90–350 × 10⁶) in many *Rhizobium* strains is now well established[4–6] and earlier genetic evidence suggested that at least some of the genes required for symbiosis were plasmid-linked[7,8]. More recently, Johnston *et al.*[9] found evidence that genes required for nodulation were carried on a plasmid in *Rhizobium leguminosarum*. We now report hybridisation between restriction fragments of plasmid DNA from *R. leguminosarum* and DNA encoding part of the structural genes for *Klebsiella pneumoniae* nitrogenase. Our results provide evidence that at least some of the *Rhizobium nif* genes are carried on plasmids indigenous to the strains examined.

Overlapping sequences of *K. pneumoniae nif* DNA which together encode the 15 known *nif* genes have been cloned on small amplifiable plasmids (refs 10 and 11 and unpublished results of M. C. Cannon and F.C.C.). The *nif* genes carried on plasmids pSA30 and pCM1 are shown in Fig. 1. The three structural genes for nitrogenase, *nif*KDH and part of *nif*E are encoded by a DNA fragment (MW 4.2 × 10⁶) cloned in pSA30. An overlapping fragment carrying *nif*Q–E and part of *nif*K is

cloned in pCM1 (refs 11, 12). These plasmids were used as radioactive probes to check for the presence of *nif* DNA sequences in *Rhizobium* plasmids. Homology between *nif* DNA from *K. pneumoniae* and *Rhizobium* was expected because: (1) all characterised nitrogenase proteins show a high degree of similarity in their physicochemical properties; (2) component proteins of nitrogenase from different sources form active heterologous enzyme complexes in many of the cases examined; (3) statistical analyses of the amino acid composition of different nitrogenases predicted a high degree of sequence homology[13].

Plasmid DNA from three strains of *R. leguminosarum* was examined. Strain LPR1705, which is a derivative of the wild-type strain A171, nodulates (Inf^+) *Pisum sativum* effectively (Eff^+)[5]. LPR180, which is Inf^-, was isolated as a non-gummy variant of LPR1705 (ref. 5). JB897 (*phe, trp, str*), which is a derivative of *R. leguminosarum* strain 300 (ref. 14), nodulates peas effectively. The MWs reported[5,6] for at least three plasmids detected in strains LPR1705 and JB897 fall within the ranges, $100–110\times10^6$, $165–200\times10^6$ and $200–240\times10^6$. The plasmid of MW $100–110\times20^6$ was absent in strain LPR180.

The procedure used to investigate *Rhizobium* plasmids for the presence of sequences homologous to *Klebsiella nif* DNA involved: (1) quantitative purification of *Rhizobium* plasmid DNA (refs 15 and 16 and unpublished result of M.P.N. and R.K.P.); (2) digestion of the DNA with restriction endonuclease *Eco*RI; (3) separation of the DNA restriction fragments by agarose gel electrophoresis; (4) denaturation of the DNA fragments in the gel; (5) transfer of the single-stranded DNA bands to nitrocellulose sheets using the Southern technique[17]; (6) hybridisation with probes of *Klebsiella nif* or control DNA labelled with ^{32}P *in vitro*[16,18]. Figure 2 shows the hybridisation results obtained with the nitrogenase structural gene probe, pSA30. Two DNA bands (MWs 1.67 and 1.33×10^6) from each of strains LPR1705 and LPR180 hybridised to the probe. The hybridisation was weaker with the smaller band from both strains. Three bands (MWs 5.8, 1.67 and 1.4×10^6) from strain JB897 hybridised, one more strongly than the others to pSA30. When pACYC184, the vector for the *nif* genes of pSA30 (Fig. 1), was used as a probe, hybridisation to the above bands was not observed, indicating that the hybridisation of these bands with pSA30 was *nif*-specific. A third band (MW 3.41×10^6) from LPR1705 which hybridised weakly to pSA30 also hybridised to the pACYC184 probe and therefore is probably not *nif* DNA. Further evidence which suggested that the hybridisation was *nif*-specific was obtained from a control experiment in which hybridisation was not observed between pSA30 probe DNA and *Eco*RI digestion fragments of large plasmid DNA from *Agrobacterium tumefaciens* strain Ach5 (ref. 19), a non-nitrogen-fixing member of the Rhizobiaceae. Plasmid pCM1, a probe which carries part of the nitrogenase structural gene, *nif*K and 11 of the 12 other identified *nif* genes, did not hybridise. This suggests that detectable homology between *Rhizobium* and *Klebsiella nif* DNA is confined to part of the nitrogenase structural genes.

We conclude from these results that the *Rhizobium* plasmid DNA examined contains sequences which are homologous to part of the structural genes for nitrogenase from *K. pneumoniae*. This is strong evidence that at least some of the structural genes for *R. leguminosarum* nitrogenase are plasmid borne. These genes cannot be on the plasmid of MW $100–110\times10^6$ in LPR1705 because this plasmid is absent in the Inf^- derivative strain LPR180 which gave an identical hybridisation pattern.

We have also examined plasmid DNA from *Rhizobium meliloti* L5-30 for the presence of sequences homologous to *K. pneumoniae nif* genes. Intensive investigations have revealed only one plasmid of MW 90×10^6 in this strain[5,6]. Our preliminary results show that two *Eco*RI fragments of DNA (MWs 1.82 and 1.6×10^6) hybridised to the *nif* DNA of pSA30 but not of pCM1. Ruvkun and Ausubel (personal communication) have observed homology between *Rhizobium trifolii* plasmid DNA and the *nif* genes on pSA30, which is consistent with the transfer of *nif* genes from *R. trifolii* to *K. aerogenes* reported by Dunican and Tierney[8]. These results suggest that the presence of *nif* genes on indigenous plasmids is widespread among *Rhizobium* species. These plasmids can now be investigated for self-transmissibility using the method reported by Beringer *et al.*[20] for inserting the transposon Tn*5* into *Rhizobium* plasmids.

Our results demonstrate that a combined molecular and genetical analysis of *Rhizobium nif* genes is now possible. Probes of *Klebsiella nif* DNA encoding homologous parts of the

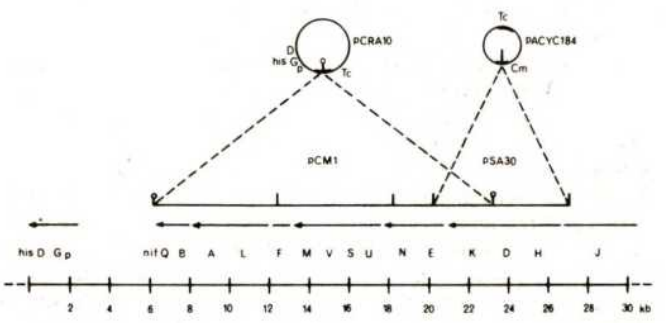

Fig. 1 *Nif* DNA restriction fragments cloned in pCM1 and pSA30 (ref. 9). Symbols for restriction endonuclease sites are: *Hin*dIII, ↥ and *Eco*RI, ⊥. The *his–nif* DNA region and the cloning vectors, pCRA10 and pACYC184, are drawn to the same scale. The arrows indicate *nif* and part of the *his* operons and their direction of transcription—*nif*F and *nif*J are monocistronic operons. The map of *nif* genes and operon structure are from MacNeil *et al.*[21], Riedel *et al.*[12] and Merrick *et al.* (in preparation). Tc and Cm are symbols for tetracycline and chloramphenicol resistance genes.

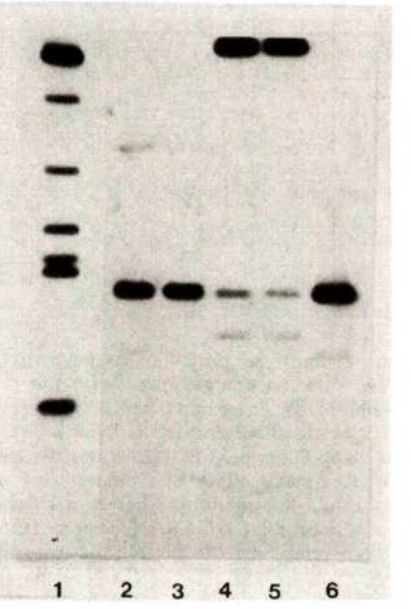

Fig. 2 Autoradiogram of ^{32}P-labelled pSA30 DNA hybridised to a Southern transfer of control DNA and of *Eco*RI-digested plasmid DNA from *R. leguminosarum* strains. *Eco*RI-generated fragments of *Rhizobium* plasmid DNA, separated by agrose gel electrophoresis were transferred to a nitrocellulose sheet and hybridised to the radioactive probe by a modification[16] of the Southern[17] method. pSA30 probe was labelled *in vitro* to a specific activity of $1–2\times10^8$ d.p.m. per μg (ref. 16). DNAs on the nitrocellulose sheet were: lane 1, MW standards (5.1, 4.15, 2.65, 2.2, 1.9, 1.69, 0.96×10^6) obtained by combining 100 pg of pSA30 DNA digested with *Eco*RI, 200 pg of pSA30 DNA digested with *Eco*RI + *Hin*dIII, and 400 pg of pCM1 DNA digested with *Eco*RI; lanes 2–6, plasmid DNA (2 μg) for strains LPR1705 (lanes 2 and 3), JB897 (lanes 4 and 5) and LPR180 (lane 6).

structural genes for nitrogenase could be used to clone *Rhizobium nif* genes, and all the *nif* mutants of *K. pneumoniae* which have been characterised in the past decade are potential hosts for examining such cloned material. These probes could also be used to determine the locations of *nif*::Tn insertion mutations and so to construct a physical map of the *Rhizobium* nitrogenase genes analogous to that of *K. pneumoniae*[12].

We thank Giovanna Bagnoli and Linda Witts for assistance and John Postgate for constructive criticism of the manuscript. This work was supported in part by an EEC grant (no. 441).

Inhibition of spinach glyceraldehyde-3-phosphate dehydrogenases by pentalenolactone

Karlheinz Mann & Dieter Mecke

Physiologisch-chemisches Institut, University of Tübingen, Hoppe-Seyler-Strasse 1, D-7400 Tübingen, FRG

The antibiotic pentalenolactone, isolated from the fermentation broth of various species of *Streptomyces*[1–3], has three different forms depending on culture conditions and purification procedure: E (epoxide; Fig. 1), D (diol) and C (chlorhydrine). The latter two derive from E by cleavage of the epoxide ring with insertion of the elements of water and HCl, respectively. As *in vitro* studies have shown[6], pentalenolactone inhibits glycolysis by inhibiting specifically glyceraldehyde-3-phosphate dehydrogenase (EC 1.2.1.12), but no other enzyme was known to be affected. The inhibition is irreversible and is similar whether the enzyme comes from *Escherichia coli*, yeast or rabbit muscle. We report here that the antibiotic has different effects on the three classes of glyceraldehyde-3-phosphate dehydrogenases that occur in spinach leaves, and we demonstrate its high specificity for the glycolytic enzyme.

We studied the enzymes of spinach because higher plants contain three different types of dehydrogenases which have glyceraldehyde-3-phosphate as substrate. Two of them are phosphorylating enzymes[7,8], distinguishable because one functions in glycolysis, is NAD-specific and located in the cytoplasm (EC 1.2.1.12), while the other is located in the chloroplasts and functions in the dark reactions of photosynthesis, being active with both NAD and NADP (EC 1.2.1.13).

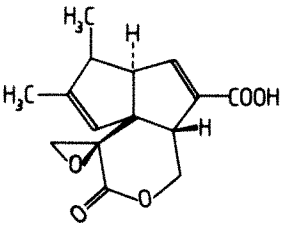

Fig. 1 Structure of pentalenolactone E (refs 4 and 5).

The third catalyses an irreversible and phosphate-independent reduction with NADP as cofactor and is located in the cytoplasm (EC 1.2.1.9; ref. 9).

Pentalenolactone was isolated from the fermentation broth of *Streptomyces arenae* strain Tü 469 by chromatography on XAD-2 resin, silica gel and Sephadex LH-20 as before[6]. Glyceraldehyde-3-phosphate dehydrogenases from spinach were enriched and partially purified, as described by Pupillo *et al.*[7], by ammonium sulphate fractionation, acetone precipitation, gel filtration, and separation of different enzymes by DEAE-cellulose–chromatography. (Rabbit muscle enzyme and all substrates and cofactors were purchased from Boehringer, Mannheim.)

As Fig. 2 shows, the inhibition of the two phosphorylating enzymes by pentalenolactone was time-dependent. Enzymes were incubated for various times with the antibiotic at room temperature before substrate was added. The activity of both enzymes declined rapidly during the first 2 min, but about 15 min of incubation were necessary for maximal inhibition. We therefore adopted this incubation time in subsequent experiments. Figure 3 shows the concentration dependency of the action of pentalenolactone. Compared with the rabbit muscle enzyme—the most sensitive tested so far—the cytoplasmic NAD-specific spinach enzyme required six times as much antibiotic for 90% inhibition. As Table 1 and Fig. 3 show, this is about the same amount needed to inhibit other glycolytic glyceraldehyde-3-phosphate dehydrogenases. Thus with respect to sensitivity to pentalenolactone, the glycolytic enzymes of the different species belong to the same class. On the other hand, the

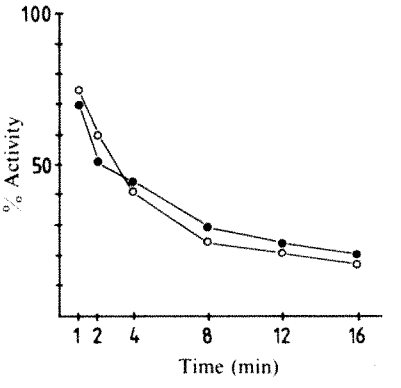

Fig. 2 Time dependency of glyceraldehyde-3-phosphate dehydrogenase inactivation by pentalenolactone. The enzymes were assayed in 0.1 M imidazole buffer, *p*H 7.4, containing 5 mM EDTA, 5 mM mercaptoethanol, 5 mM sodium arsenate, 2.5 mM coenzyme, and 0.15 IU enzyme in a total volume of 2.1 ml. Pentalenolactone E at a final concentration of 7 μM (chloroplast enzyme) or 1.5 μM (cytoplasmic enzyme) was added in 100 μl of methanol. In a control experiment with 100 μl pure methanol it was assured, that methanol does not disturb enzyme activity. The assay was started by addition of 250 μM (final concentration) D-glyceraldehyde-3-phosphate and the absorbancy change at 340 nm was measured for 1 min. The ordinate shows the incubation time before substrate addition in minutes. ○, Cytoplasmic enzyme; ●, chloroplast enzyme.

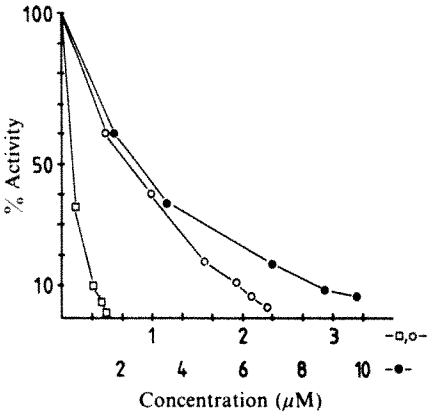

Fig. 3 Concentration dependency of pentalenolactone action. Assay conditions and enzyme concentrations were as detailed in Fig. 2, except for the non-phosphorylating glyceraldehyde-3-phosphate dehydrogenase (not shown, see text), when sodium arsenate was omitted. Incubation time before substrate addition was 15 min. □, Rabbit muscle enzyme; ○, spinach cytoplasmic enzyme; ●, spinach chloroplast enzyme. Note the change in scale on abscissa between glycolytic enzymes and chloroplast enzyme.

concentration of antibiotic needed to inhibit the chloroplast enzyme to the same degree is about 25 times those needed to inhibit the rabbit muscle enzyme. Thus, the chloroplast enzyme belongs in another group, as expected from its more variable cofactor dependency. To ensure that the NADP used in the chloroplast enzyme assay was not interfering with inhibition, some assays were done with NAD. The activity of a constant amount of chloroplast enzyme with NAD was about two-thirds of that obtained with NADP, but percentage inhibition with a controlled amount of pentalenolactone was the same. Thus, in a 2.5-μM assay solution the activity of the enzyme with NAD decreased 44% and the activity with NADP 50%. With a 3.5-μM solution 38% of activity was left in both cases. Furthermore, we confirmed that the protein-free plant extract contained nothing that interfered with the action of pentalenolactone. The third glyceraldehyde-3-phosphate converting dehydrogenase of higher plants, the nonphosphorylating enzyme, could not be inhibited to a significant degree by pentalenolactone concentrations up to 150 times that needed to inhibit completely the same amount of rabbit muscle enzyme.

Table 1 Relative sensitivities of different glyceraldehyde-3-phosphate dehydrogenases (GAPDH) to inhibition by pentalenolactone

Enzyme	Relative sensitivity
NAD-GAPDH, rabbit muscle	1*
NAD-GAPDH, *E. coli*	1.4*
NAD-GAPDH, yeast	3.2*
NAD-GAPDH, spinach	5.7
NAD(P)-GAPDH, spinach	24.5
NADP-GAPDH (nonphosphoryl. spinach)	>150

Sensitivities are expressed as concentration for 90% inhibition divided by concentration for 90% inhibition of muscle enzyme.
* Values from ref. 10.

Our results show that pentalenolactone is a universally applicable inhibitor of glycolysis. The difference in sensitivity to the antibiotic, shown by the three plant enzymes which function in different pathways, stresses the specificity of its action. The binding site of pentalenolactone to glyceraldehyde-3-phosphate dehydrogenase is not known, but Hartmann[10] has shown that the inhibitor strongly interferes with the binding of glyceraldehyde-3-phosphate to the rabbit muscle enzyme. Thus it seems possible that the substrate-binding part of the enzyme's active site is blocked by the inhibitor. The glycolytic enzymes from various organisms, having the same substrates and cofactors, and consequently a very similar active site, also show the same sensitivity to pentalenolactone. A minor change in the active site, indicated by the ability of the chloroplast enzyme to use NAD as well as NADP, is sufficient to decrease the enzymes' sensitivity to pentalenolactone considerably. Because of the epoxide structure of pentalenolactone E, its irreversible binding shown[10] for the rabbit muscle enzyme and also indicated for the spinach enzymes by the time-dependency of inhibition, and its interference with substrate binding, we conclude that it is covalently bound to the essential thiol group known to react reversibly with glyceraldehyde-3-phosphate during the catalytic cycle. The identification of the pentalenolactone binding site is in progress in our laboratory. We further speculate that the nonphosphorylating plant enzyme, which converts glyceraldehyde-3-phosphate to 3-phosphoglyceric acid, and is completely insensitive to inhibition by pentalenolactone, has no essential sulphydryl group in its active site.

Erratum

In the article 'Tholins: organic chemistry of interstellar grains and gas' by C. Sagan and B. N. Khare, *Nature* **277**, 102–107, the following errors, generated at *Nature*, during editing, should be corrected: In paragraph 2 line 2, for H_2C read H_2S. In paragraph 3 line 11, for Sagan[8] read Sagan[10]. In paragraph 4 line 1, experimentally[9] should read experimentally[11]. In Table 2 the molecules listed, not the Table itself, are courtesy of Professor L. E. Snyder. The reference for the column labelled 'Gas phase spark' should be 37 not 30, and the reference for the column labelled 'Interstellar frost' should be 11 not 9. the last four lines of Table 2 should read:

Molecule

Propionitrile

$CH_3CH_2C{\equiv}N$

6. Cyanodiacetylene Pentenenitrile-H etc.
$CH{\equiv}C{-}C{\equiv}C{-}C{\equiv}N$
8. Cyanotriacetylene Benzonitrile ring breakage-H
$CH{\equiv}C{-}C{\equiv}C{-}C{\equiv}C{-}C{\equiv}N$
10. Cyanoctatetrayne
$CH{\equiv}C{-}C{\equiv}C{-}C{\equiv}C{-}C{\equiv}C{-}C{\equiv}N$

In paragraph 6 the penultimate sentence should read: 'The fit of four spectral features between 3 and 4 μm to an accuracy of 0.3 μm will occur by chance with a probability 10^{-8}.' In paragraph 9 line 13, for tholins[33] read tholins[41]. In paragraph 13 line 3, for spluttering read sputtering, and in the same paragraph line 5 should read 'positive ion-molecule reactions may produce the simplest inter-'. In paragraph 15 line 11, for induces[34] read induces[38]. In paragraph 16 line 6, the name of H. C. van de Hulst is misspelled. In reference 5 the authors of the paper in *Astrophys. J. Suppl.* are C. Sagan and E. E. Salpeter.

Corrigendum

In the letter 'Combined effects of adrenaline and insulin on active electrogenic Na^+–K^+ transport in rat soleus muscle' by J. A. Flatman and T. Clausen, *Nature* **281**, 580, in Table 3 the units for serum insulin concentration should read $\mu U\ ml^{-1}$.

reviews

Good food for all

Kenneth Mellanby

Food for the Future. By K. Campbell. Pp.178. (University of Nebraska Press: Lincoln and London, 1979.) £8.75.

FOR some years those whom the popular press call ecologists have been telling us that mankind is doomed to perish from starvation. They say that we are not producing enough to feed the present world population of four thousand million, and that the shortage of energy and other resources, and the damage intensive farming is doing to the environment, means that in the future we will produce less, not more food. As the population is expected to be over six thousand million by the year 2000, and as it will probably increase further after that, the future seems desperate. Professor Keith Campbell believes that these doomsday men are "just plain wrong".

He is, of course, not the first to say this. Many agricultural scientists have suggested that, even without fundamental advances in farm practice, vastly greater productivity is possible in many parts of the world. The most striking report, published in 1975 by P. Buringh, H.D.J. van Heemst and G.J. Staring of the Agricultural University, Wageningen in the Netherlands, shows how the world's cereal production might be increased forty-fold. This would feed any possible population increase for many years to come.

Of course everyone, including Professor Campbell, must agree with the Malthusian view that if the world population continues to increase there must eventually be more than can be fed, but there are reasons for believing that this situation is a long way off, or, more hopefully, that population growth will be contained at a satisfatory level (as far as food production is concerned). This view is set out here, using familiar data, based on the fall in birth rate in both developed and developing countries. It is suggested that the most likely estimate is that the world population will stabilise at about eleven thousand million at the end of the twenty-first century; if so there is little doubt that they can all be fed.

Professor Campbell discusses the problems which will affect future agricultural productivity. He shows that these are of two types. First we have the scientific and agricultural problems — how much food can we produce; will there be land, water, energy and other resources; can the land sustain the present pressure? Secondly we have the economic and political problems — will farmers make a decent living; or will economic and social pressures make them work below their maximum level of productivity?

The first set of problems are dealt with briefly and in a familiar way. Even the most intensive systems use only a tiny fraction of the energy used by man in his other activities, so there should be enough for food production. Global supplies of fertilisers, including phosphate, are adequate for centuries. There is little evidence that food farming, no matter how intensive, is doing anything else than increasing the land's fertility.

Professor Campbell believes that productivity can be greatly increased if research is better organised to deal with the practical problems of the least productive countries. He is critical of much present-day research, particularly in universities, and complains that it is often divorced from the advisory ("extension") services. This view will be endorsed by many older agriculturalists in England and Wales, who regretted the post-War reorganisation which set up the National Agricultural Advisory Service (NAAS), taking advisory work from the universities, cutting off the research workers from the farmers, and producing the usual pullutation of unproductive bureaucrats. Nevertheless I fear that Campbell may be guilty of hubris, for assuming that more relevent research will certainly produce results which will improve food production. Unfortunately we cannot foretell the outcome of original research. But it will probably do some good, even if not as much as is here suggested.

The most interesting sections of this book are those which deal with the other constraints reducing potential food production. The environmentalists who wish to go back to peasant farming are given short shrift; Campbell believes that modern techniques, including chemicals, must be used efficiently, and that there need be no damage to the environment (even if some wildlife may be exterminated). More serious consideration is given to economic and political policies which encourage low productivity. Price control, quotas and other measures adopted by governments to influence agriculture receive severe and, to me, convincing criticism.

It is clear that poverty, not low food production, is the main cause of hunger in the world today. Wheat prices rose in 1973 because Russia had the money to buy a larger than usual share of the world surplus, thus pricing the poorer countries out of the market. This grain was bought to feed pigs, which had more economic power than starving peasants in the third world. Professor Campbell optimistically suggest that economic growth, world wide, will make increased food production profitable. Some readers will be more sceptical, but they will agree that it will be wise for greater food production, with greater self sufficiency, to be encouraged in poor countries, where internal food movements will be easier than between different sovereign states.

Incidentally, as a good economist, Professor Campbell wishes to give the customer what he wants. He has no time for the suggestion that the amount of animal protein in consumer diets should be reduced. Nevertheless it is realised that where intensively-kept livestock is fed on food which man could consume, more than half the protein and over 90% of the energy is wasted. Today world production is already sufficient to give more than the present population a nutritionally adequate, though dull, largely meatless diet. While we have surpluses, there is no reason why they should not be used to produce luxury food for the richer nations. Whether the rest of the world will ever be able to afford such diets is, in my opinion, doubtful. I am comforted by the knowledge that in a real crisis we could reorganise our feeding habits to ensure that the world's population could be adequately nourished. I only hope that Professor Campbell is justified when he says that "the world can look forward to substantially better diets in the future than were ever enjoyed in the past". □

Kenneth Mellanby was on the staff of Rothamsted Experimental Station from 1955-61, and is author of Can Britain Feed Itself?

Nuclear magnetic resonance

NMR and the Periodic Table. Edited by Robin K. Harris and Brian E. Mann. Pp. 459. (Academic: London and New York, 1978). £35.

THE great bulk of nuclear magnetic resonance work has been done on the nuclei of hydrogen, fluorine,phosphorus, carbon, boron and nitrogen, but most elements of the Periodic Table have at least one nuclide with a magnetic moment. Although quite a lot of work on many elements has been done in a few laboratories in the past twenty years, it is only relatively recently that commercial instruments with good enough resolving power and sensitivity have encouraged their wide use. In this book the editors and an authoritative and experienced group of authors have gathered together most of the work described so far in the literature, together with some unpublished work. The commonly studied nuclei mentioned above are dealt with only briefly and most of the book is devoted to work on the rest of the Periodic Table. The result is a remarkably comprehensive and fascinating account of an extraordinary range of chemical studies using chemical shifts, nuclear relaxation times, and scalar coupling constants.

The chapters on the various groups of elements also provide tabular data culled from the literature and presented in a convenient way which is likely to be valuable to those working or planning to work on those nuclei; and the coverage of the literature seems to be remarkably comprehensive.

There is a short account of experimental methods, and brief chapters to remind the reader about the theory of the chemical shift, nuclear spin coupling and nuclear relaxation. These are not intended for the beginner nor are they authoritative accounts, but are very useful for reference from time to time when reading other parts of the book.

Dr Harris and Dr Mann are to be congratulated on producing such a useful and interesting book and on having persuaded so many co-authors to cooperate in writing such a compendium.

Rex Richards

Sir Rex Richards, formerly Dr Lee's Professor of Chemistry at the University of Oxford, is now Warden of Merton College and Vice-Chancellor of the University of Oxford, UK.

Geochemical mapping

Regional Geochemical Atlas: Orkney. Compiled by the Institute of Geological Sciences. (Institute of Geological Sciences Bookshop: London, 1979.) £35. *An Introduction to the National Geochemical Data Bank.* (IGS Computer Application Report No. IGS/CAR/78/2.) Second edition. (Institute of Geological Sciences Bookshop: London, 1979.)

THE acquisition of regional geochemical data, based on the collection and analysis of steam sediment samples, had its origin in mineral exploration geochemistry. Individual mining and prospecting organisations would undertake regional geochemical surveys in order to delineate those parts of an exploration area which had the highest probability of containing mineral deposists.

The areas covered by such surveys varied from a few square kilometres to tens or even hundreds of thousands of square kilometres, and great success was achieved with the technique. The data obtained, however, seldom became widely available due to the competitive nature of the mining industry, and as a result some areas in well mineralised environments were surveyed many times. Certain areas in the Irish Republic, for example, are believed to have been surveyed five or six times.

Subsequently, further applications of regional geochemical data have been discovered. The relationship between certain human and animal ailments and the occurrence of abnormally high, or abnormally low levels of certain specific elements in the soils and vegetation of certain areas has been appreciated. The influence of the levels of many elements upon the success or failure of some crops has also been investigated. There can be little doubt that many new uses of regional geochemical data will be discovered in the future, especially if such data become freely available. The publication of the *Regional Geochemical Atlas* by the Institute of Geological Sciences will be especially welcome in this connection.

In the first instance, the atlas will cover the whole of Scotland. The atlas is not the first such publication to appear. As long ago as 1973, the Applied Geochemistry Research Group at Imperial College, London, produced its *Provisional Geochemical Atlas of Northern Ireland;* the somewhat less ambitious *Reconnaissance Base Geochemistry of Parts of the Counties Wicklow, Wexford, Kildare and Dublin* was published by The Geological Survey of Ireland in 1977; and the Applied Geochemistry Research Group published the impressive *Wolfson Geochemical Atlas of England and Wales* (Oxford University Press: Oxford) in 1978.

In the IGS atlas, the distribution of 15 elements in stream sediments is illustrated in the same number of maps, plus another showing the distribution of uranium in stream waters. Other maps illustrate the relief, geology and mineralisation of the area, together with data collected from a smaller number of sites on the *p*H and conductivity of the streams themselves.

The maps, on a scale of 1:250000, were produced by automated cartographic methods which were developed jointly by the IGS and the NRTC Experimental Cartography Unit. The level of the relevant element at each sample site is illustrated graphically by the use of lines which are proportional in length to the concentration of the element in the sediment, the lines for each element being orientated in a specific direction.

This method of presentation has the advantage that the results for each sample site are clearly represented, as distinct from the smoothed 'grey-scale' approach adopted by the Imperial College group. Whether or not this manner of data presentation can be considered to be entirely successful, however, is a matter of personal opinion. The reviewer did not find it completely satisfactory, especially where several sample sites occur in close proximity, so that individual lines tend to merge into a single mass which is difficult to interpret.

The prospect of having such regional geochemical maps freely available in the future is clearly one which will increase the scope of geochemical studies. Indeed, one can imagine the time in the future when geochemical maps are regarded as being as basic a requirement as geological maps are today. Nevertheless, many areas will have been the subject of geochemical studies other than those presented in such atlases,and the need to make the data from these studies both available and accessible is also a matter that calls for attention.

The Regional Geochemical Atlas series is part of the Department of Industry's wider Regional Geochemical Reconnaissance Programme under contract to the Natural Environment Research Council. This programme includes the IGS National Geochemical Data Bank which holds data compiled in the production of the geochemical atlases, as well as regional geochemical data from other sources. The establishment of this Data Bank is also to be welcomed, as the use of a central computer for the storage and management of geochemical data could obviously lead to a more effective use of information available.

Data to be accepted initially will be related to igneous, sedimentary and metamorphic rocks, drainage samples (that is, stream sediment samples) and soils, the results for each type of material being stored separately on the basis of geographical location. The bank will be under the control of a manager, who will be responsible for maintaining a suitable level of quality of the data in the bank. Before being archived, data will also be examined by an Advisory Committee consisting of

AMBIO A JOURNAL OF THE HUMAN ENVIRONMENT

Now distributed for the Royal Swedish Academy of Sciences by Pergamon Press

Launched in 1972, AMBIO is already recognized by many as the leading interdisciplinary periodical in the environmental sciences.

Now, with the aim of broadening an already international coverage and readership, AMBIO will be published and distributed through a joint arrangement between the Royal Swedish Academy of Sciences and Pergamon Press.

Regular issues contain general articles on current environmental problems and challenges and reports on original research in the field. Special issues give a more comprehensive treatment of some topical subjects, e.g. issues are planned on the Baltic and threatened ecosystems.

" . . . The most authoritative journal of its kind on international environmental problems."
GILBERT F WHITE, *President, Scientific Committee on Problems of the Environment, I C S U*
" . . . AMBIO is the best magazine of its kind."
IGNACY SACHS, *Centre Nationale de Recherche sur L'Environnement*
"It conveys the message on crucial environment issues in the most accurate and well-presented way."
MOSTAFA K TOLBA, *Executive Director, UNEP*

NICK TRANSLATION SYSTEM

The world's first. Packaged complete.

Naturally it is more convenient than assembling the components yourself. But even more important is its reliability.
For example, the *E. coli* DNA Polymerase I is prepared in our laboratories to ensure extremely high reproducibility. The dCTP, [α-^{32}P]- is tested for nick translation by our Biological Testing Laboratory. (Typical incorporation is 40%, and we guarantee 1 x 10^8 dpm/μg DNA.) The supercoil pBR322 Plasmid DNA control we use to test each lot of systems is included so you can check yours. Finally, the DNAse I, dNTP mixture, stop-buffer, and sterile deionized water are optimized for compatibility and stability. Approximately twenty assays can be run.
A bulletin describing this exclusive system is yours for the asking.

HIGHEST STANDARD OF QUALITY IN BIOLOGICAL REAGENTS FOR THE STUDY OF NUCLEIC ACIDS, SYNTHESIS AND PROCESSING.

RIBONUCLEASE H–1
(From Calf Thymus)

This enzyme can be effectively used:
1. In the digestion of RNA moiety of the hybrid after Reverse Transcriptase Assay to avoid the deamination of cytidine in the CDNA, resulting from the alkalihydrolysis of the RNA moiety;
2. In the removal of the poly (A) stretches found on the RNA messengers;
3. As a restriction enzyme trideoxynucleotides in the DNA matrix, since it will exclusively attack the guanosine moiety of the RNA. Most of the RNA do not hybridize with trideoxynucleotides because they are double stranded. Only the regions at the single stranded loops can by hybridized with the deoxytrinucleotides so that only a few nicks in the RNA molecule will appear after the hybridization with the deoxynucleotides and subsequent treatment with RNase H.

Cat. No. EER-C $315.00/500 units $195.00/250 units $95.00/100 units

RIBONUCLEASE PHY I
(RNase I from Physarum polycephalum)

This novel enzyme preferentially digests G, A and U residues, allowing discrimination between C and U in RNA sequencing methods (1,2). This makes possible sequencing of terminally labeled RNA by the gel method (2).
One arbitrary unit gives partial digestion of 1 microgram of RNA under conditions described in ref. (2).

Cat. No. ERN-PHY $145.00/100 units

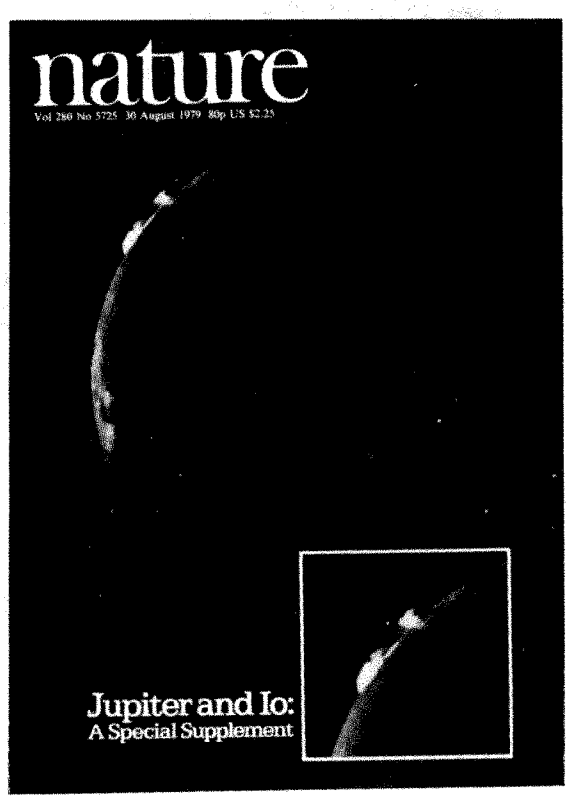
THE MACMILLAN DICTIONARY OF ASTRONOMY

Valerie Illingworth



This Macmillan Dictionary reflects the explosive growth of astronomy in the last few years. It contains up-to-date references to the many exciting developments and discoveries that have been made in these years as well as to established theories.
It is a concise and comprehensive work; fully cross-referenced, it contains illustrations and diagrams making it the ideal personal reference book for both the specialist and the interested layman.

specialists in each particular field; and during the archiving process, a variety of checks will be applied in order to maintain quality control.

It is perhaps the question of quality control which presents the most important point of contention over the question of a data bank of this type, for not only will the quality of data received vary from project to project, but the level of quality of data that is acceptable to the users of the bank will also vary. Thus a data set that is rejected by the bank as being of unsatisfactory quality, would be denied to a user to whom it might be quite acceptable. It would perhaps be more satisfactory if data sets were accepted into the bank on the basis of an accompanying quantitative statement of data quality, which would enable the user to select or reject the results of any particular project.

These two publications, therefore, may be seen as heralding a new approach to the study of geochemical problems. It is good to see the IGS leading the way in these important matters.

C. H. James

C. H. James is Senior Lecturer in Economic Geology at the University of Leicester, UK.

Life through Earth's history

The Encyclopaedia of Prehistoric Life. Edited by Rodney Steel and A.P. Harvey. Pp. 218. (Mitchell-Beazley: London, 1979.) £12.

THE editors of an encyclopaedia have a very exacting task in ensuring that their volume lives up to the name, not only in its facts but in its balance and overall content. To ensure factual correctness a formidable array of palaeontologists is here listed as contributors, totalling some 23, most of whom have an international reputation; some of them would no doubt figure on a list of the world's leading palaeontologists, but they hardly constitute such a list, as the dust-cover would have us believe.

The editors are Rodney Steel, a journalist, and Anthony P. Harvey, a librarian; both clearly have an absorbing interest in palaeontology. In their role as editors, however, they have failed to make full use of the talents of their team of contributors, several of whom only have one subject entry, and rely very heavily on their own contributions, which amount to almost 40% of the entries in the book. Rodney Steel contributes on vertebrate palaeontology (in considerable detail), on localities and formations (almost exclusively dealing with vertebrate fossils and omitting, for instance, Ediacara, the Bundenbach Slate, and so on), and on various other subjects with considerably less success. Anthony Harvey uses his bibliographical knowledge to provide biographical information on pioneering palaeontologists, and short sections on institutions with palaeontological museums. Both these lists have some notable omissions but one wonders whether they have place at all in a book on prehistoric life.

There are three main non-editorial contributors, J.W. Franks on plants and L.B. Halstead and R.J.G. Savage on vertebrates. These three provide authoritative reference material which is amplified by beautifully executed line and stipple drawings which characterise the whole book.

The composition of the rest of the contributing team and the use to which they have been put, raise many queries. One questions the logic of using five vertebrate palaeontologists (in addition to Rodney Steel who writes extensively on vertebrates). There are five workers on fossil arthropods, only one of whom has contributed on this phylum (which merits a meagre nine entries); of these five, three work on trilobites but none has contributed to the "trilobite" entry. There are two authors who have worked on the Burgess Shale fauna, but neither has written under that heading. Some 17 of the contributors have produced in total well under 20% of the entries.

The standard of the entries by the professional palaeontologists is high, but it is very clear that some (at least) of the authors have not had the opportunity to check proofs of their own sections. Under "echinoderms", for instance, blastoid hydrospires appear as "hydropores" and "hydrospores", and an inexcusable editorial insertion of "(spore cases)" appears after the word "theca".

The book is excessively vertebrate-oriented; to widen its appeal, some leaning towards the more conspicuous faunas is excusable. Here though, reasonable limits are exceeded. Over a quarter of the diagrams are of mammals (some groups are dealt with in great detail, so that elephants, mammoths and mastodons have no fewer than eleven large size drawings); another quarter is of reptiles, and a further fifth of other vertebrates. With limited space left for plants and invertebrate groups, the choice of diagrams is sometimes curious. For instance, many echinoderm classes are unfigured, yet there are two large drawings of Lower Jurassic ophiuroids and four views of one species of echinoid.

Molluscs too are poorly served. There is no entry under the heading "cephalopods", although ammonites and belemnites do appear under separate entries. Nautiloids and early ammonoids are described under "ammonites", but coleoid groups such as octopuses, cuttlefish and squids (the latter two at least with a healthy fossil record) do not merit entries. There are no diagrams of such molluscan groups as scaphopods, polyplacophorans or monoplacophorans, and no mention of segmentation under the latter or under *Neopilina* (mentioned separately, without cross-reference, under "Living fossils").

One of the problems the user of this book must face is inconsistency. Here a firm editorial hand should have spotted these probems. Thus Stromatoporoids and Stromatoporata are treated (by the index at least) as separate organisms; this confusion is compounded by a figured bryozoan being labelled as *"Stromatopora"* rather than *Stomatopora*. Bivalves are referred to as such in the text in some places, and as pelecypods in others — only the latter rates an entry in the index. Ranges of organisms vary too — the first belemnites are stated (correctly) to occur in the Carboniferous under "Belemnites", but in the Permian under the entry for that system. Ranges of some fossil groups are incorrectly stated.

Each geological system has an entry, and most are accompanied by a small time-scale chart showing subdivisions of that system. These are clearly not the authors' work, but are culled from a well-circulated colourful chart which is, unfortunately, full of errors. These are perpetuated in the book, but some new errors have crept in too.

Blackie

Biochemical Systematics and Evolution

Andrew Ferguson, Queen's University, Belfast

This is a review of the most recent developments in biological systematics, written at a level suitable for undergraduates and postgraduates in the biological sciences. The author lays special emphasis on the technique of gel electrophoresis. Throughout, he selects examples which best illustrate particular concepts or applications, although most examples concern animals and particularly the vertebrates.

Suggestions for further reading are provided for each chapter and there are extensive bibliographic citations in the text.

In addition to the numerous line drawings there are fourteen glossy colour charts. Eleven feature vertebrate phylogenies in considerable detail, with many genera mentioned. In contrast two charts of plant and invertebrate phylogenies are very poor and largely at phylum level; the latter lacks a time-scale.

The over-emphasis on vertebrates throughout the book reaches ludicrous proportions when, under the heading "Zone fossils", vertebrate groups receive more space than invertebrates.

There is a glossary which is again heavily vertebrate-oriented. The geological entries are sometimes appallingly incorrect and could not have been written by a professional geologist; the authorship of this section is not given.

The book is presumably aimed at the layman who wants to learn something about life through Earth's history. If he seeks information on extinct vertebrates, then this may be the book for him, but it will otherwise have a limited appeal. In spite of the excellence of the great majority of the drawings and its wealth of detailed information on vertebrate fossils, its inaccuracies and inconsistencies together with, for most readers, an unacceptable imbalance in its content, render the title *Encyclopaedia* a pretentious one. Though it is attractively laid out and handsomely bound, at £12 for 218 pages it is an expensive way to cover your coffee-table.

J.C.W. Cope

J.C.W. Cope is Senior Lecturer in Geology at University College, Swansea, UK.

Artificial intelligence at MIT

Artificial Intelligence. (Two volumes). Edited by P.H. Winston and R.H. Brown. Pp.492 and 486. (MIT Press: Cambridge, Massachusetts, and London, UK, 1979.) £16.25; $26 each volume.

AMONG the new scientific arts which have arisen since World War II, artificial intelligence must surely be among the most consequential and the most widely misconstrued. Yet its practitioners are neither diffident nor ambiguous in defining their field of study. "Its central goal", say P.H. Winston and M. Brady in their foreword to a new series from MIT Press, "is to make computers intelligent, both to make them more useful and to understand the principles that make intelligence possible".

The first fruit of the MIT Press series is a two-volume collection of 29 papers by graduate students, young post-doctoral workers and senior staff at the Massachusetts Institute of Technology. They are scattered over a variety of AI-related topics and first appeared, usually in longer form, as technical memos. The editors, P.H. Winston (who now directs MIT's AI Laboratory) and R.H. Brown, have grouped them into sections as follows: in Volume 1 — expert problem solving, natural language understanding and intelligent computer coaches, representation and learning; in Volume 2 — understanding vision, manipulation and productivity technology, computer design and symbol manipulation.

The reader who hopes for a true perspective view, a shining framework of deductively related principles and laws, will recoil from this congeries. Thus some pre-Newtonian seeker after a science of mechanics might have recoiled from Leonardo's notes on motion, weights, impact and moments of force. Technology's most thrilling advances commonly take place through spasms of untidy thought and activity. While waiting for the orderly abstraction of the theoretician, we may have to quarry general principles from the disorder of notes made in the heat of the struggle by the protagonists themselves. The editors of this book do, however, give conscientious aid to the quarrying process. Very full summarising prefaces precede each section, with an additional shorter note on each chapter. Newcomers to the field will be particularly grateful where specific AI techniques are listed and sign-posted to individual papers.

Some contributions, such as Stallman and Sussman on mechanised circuit analysis, represent deep and thorough finished studies. Others record brave first skirmishes with problems which will not fall before many such assaults have spent themselves. Johan de Kleer's study of qualitative and quantitative reasoning about roller-coaster mechanics is a stimulating example, and Winston's exercise in machine learning through simile raises hope of good eventual solutions in an extremely difficult area. In Marvin Minsky's "The Society Theory of Thinking", in which "the mind is viewed as an organised society of intercommunicating 'agents'", bravery shades into audacity, and the lines of contact with neurobiological fact are stretched exceedingly thin. Yet speculation may still in this field engender aids for the practitioner, as Minsky's earlier "frames" proposal has already amply shown.

Of all the difficult problems addressed by artificial intelligence workers, common consent gives the computational analysis of vision pride of place. Among the six vision papers of the second volume, David Marr's is outstanding. From the strenuous detail and breadth of this attack, methodological lessons can be learned. One of these is summarised by Winston and Brown: ". . . it is wrong to begin with devotion to some particular type of algorithm with a view toward finding some problem that it will solve". These words reflect AI's recent change of emphasis for which the MIT school can claim chief credit, namely that intelligent behaviour can only be conjured from a sufficiently rich and massive base of empirical knowledge about the specific domain appropriately organised in machine memory.

Artificial intelligence has thus followed an opposite course to that of the mechanical crafts, which in their early days lost themselves in the properties of specific domains. It was left to Leonardo to make the all-important step of abstracting the concept of a generalised mechanism — for example, for converting between rotary and reciprocating motion — which could then be made to function in any of a variety of different specialised machines. With AI it went the other way, and for 15 years most of us were hypnotised by the promise of general mechanisms — for heuristic search, for deductive reasoning, for machine learning, and the like — as though these universals could accomplish every problem-solving task without the additional need for building in carefully articulated representations of knowledge.

Indeed for a time the MIT school went to the opposite extreme and maintained the exuberant position that domain-specific knowledge should be inextricably interwoven ("procedural embedding") into the substance of the algorithmic mechanisms themselves, instead of maintaining, as we do today, separate "knowledge bases" to which these more general mechanisms can have access. It has now been sufficiently demonstrated that the resulting loss of modularity is fatal to incremental construction and flexible adjustment of an intelligent program's packet of skills. Incremental properties are quintessential. It is refreshing to note from these volumes that the point is now taken, including at MIT.

Space does not allow mention of many other rewarding views to be had of AI people at work. Lozano-Perez's discussion of the problem of telling a robot how to move its hand illuminates the intrinsic complexity of a task at which humans are hereditary Grandmasters. The software technologist will find Hewitt on control as message-passing a source of provoking novelty. Hewitt's chapter closes a book which will irritate purists and antagonise some professionals whose orientation is to Meccas other than MIT. But to those who wish to take a dip into the fast-flowing stream of an active and authoritative laboratory, the publication of this book offers a unique opportunity.

Donald Michie

Donald Michie is Professor of Machine Intelligence at the University of Edinburgh, UK.

obituary

Lew Kowarski

LEW KOWARSKI was the last survivor of the French team that, immediately after the discovery of uranium fission, explored the chances of a nuclear chain reaction. The paper by Otto Hahn and Fritz Strassmann reached Paris about 16 January 1939 and Frédéric Joliot at once saw its tremendous implications. Hans von Halban offered his experience of neutron physics and suggested that Lew Kowarski should join the team. Within weeks they had proof that neutrons, in causing uranium nuclei to split, produced further neutrons; by April they were sure that under suitable conditions those further neutrons would produce further fissions and vice versa, a chain reaction that would lead either to an explosion or to the generation of useful power if the reaction was controlled.

Born in 1907 in St. Petersburg (now Leningrad), Lew had an insecure childhood in a divided household, as son of a Jewish businessman and a Ukrainian singer. At the age of 12 he was smuggled from the Russian revolution to Vilna (in what later became Poland) across the remnants of the German army, some months after his father had gone there. He grew into a giant; musical though he was he had to give up his piano lessons when his fingers grew too thick for the piano keys; so it had to be science. With modest support from his father he studied chemical engineering in Belgium and France.

In 1929 he enrolled in the University of Paris, studying physics and chemistry from books and supporting himself by a job in a firm that made gas pipes, a job he kept part time until 1938. In 1931 he began work on a thesis on crystal growth in Jean Perrin's laboratory, made friends with his son Francis Perrin, and got in touch with Madame Curie, her daughter Irène and Irène's husband Frédéric Joliot just when the couple discovered "artificial" radioactivity at the end of 1933. That brought them the 1935 Nobel prize for chemistry, and Joliot then became professor at the College de France. Kowarski had already been his part-time unpaid assistant for a time; he now became a paid part-time secretary, "Joliot's little typist" as the huge Russian got nicknamed; and then he got a grant that allowed him to drop his other job, of designing gas pipe systems, about which he had just written a book. He still felt an intruder in spite of his doctorate, having got into science by the back door, at the late age of 31; but he was in.

The team agreed that, in publishing, no ideas should be attributed to individuals; but later it became clear that some of the best ones had been due to Kowarski, who combined inventiveness with meticulous logic. The neutrons were slowed down in water to make them better at causing fission, but many were absorbed before they did. Kowarski urged that heavy water be used, known to absorb hardly any neutrons. It has to be extracted from ordinary water at great cost, and one firm in Norway was doing that; in March 1940 their entire stock, about 40 gallons, was moved to Paris just before the Germans attacked Norway. During that transfer those aliens, Halban and Kowarski, were interned on two separate islands! But time was running out; in May France was invaded, and in June — as instructed by Joliot — Halban and Kowarski escaped to England with their families and the heavy water.

At the Cavendish Laboratory in Cambridge new equipment was built with help from local physicists, mainly under the guidance of Kowarski while Halban negotiated with the USA. The results were promising, but much more heavy water was needed, no longer obtainable from Norway. And why should the USA help Halban, with his German manner, who waved French patents and allied himself with ICI? He seemed more intent to compete after the war than to help win it.

With influential friends and fluent English (though Kowarski soon caught up) Halban assumed a dominant position. In 1942 he was sent to Canada to set up a laboratory; Kowarski, offered an inferior post, decided to stay in Cambridge, as did some of his co-workers. Late in 1943, with some US help promised, (Sir) John Cockcroft took over from Halban, and at last Kowarski got his way: he came to Canada with his team to build a heavy-water reactor. He did it in less than a year; it was the first nuclear reactor outside the USA where Enrico Fermi had achieved the first self-sustained chain reaction in 1942.

After the war Kowarski would have liked to go back to England, where in Cambridge he had felt at home from the first day; but he felt in duty bound to return to France. Under Joliot, scientific head of the Commissariat a l'Energie Atomique, he began to prepare for nuclear power in earnest. Again he built a small heavy-water reactor, both for experimentation and prestige, which went critical late in 1948; nobody knew that the USSR had a reactor going two years before that. Bigger reactors were on the drawing board; would their main product be power or plutonium? Joliot, now an open communist, publicly refused to make atomic weapons and in 1950 was dismissed from the Commissariat. Kowarski, still working for it part-time, found a new career with CERN, nursing that young European Centre for Nuclear Research. In 1948, his first marriage broken up, he had married Kate Freundlich, daughter of a German scientist; in 1954 they settled in Geneva for good.

As CERN grew his work was gradually taken over by others; in the end he concentrated on data processing with computers, whose importance he saw earlier than most; the device for measuring bubble-chamber tracks that Paul Hough and Brian Powell built with his guidance was used all over the world. A few years' working and travelling for ENEA (the European Nuclear Energy Agency) restored his freedom to visit the USA, denied for years because of his past work with that notorious communist Joliot, and enabled him to hold visiting professorships, two extended ones at Purdue University and shorter ones at Austin (Texas) and at Boston University. In his last years he worked to warn the public against too headlong a growth of nuclear power.

Outwardly like a big jolly Russian peasant, he had a nimble mind and a fine command of both French and English. Honest to the point of bluntness, he made some enemies and many devoted friends. His interest gradually shifted from science to the philosophy and strategy of scientific organisations. Overwork damaged his health, and the single kidney he was born with began to fail years ago; on 27 July he died in a Geneva hospital, cared for by his wife and his daughter Irene from his first marriage. That he survived so long was due to medical art, his own tremendous will, and the care of his calm and gentle Kate.

Otto R. Frisch

Percy Brian

PERCY WRAGG BRIAN died at the age of 68 on 17 August 1979. He was one of the leading botanists of the day with a wide range of interests.

Percy Brian graduated from Cambridge in 1931 with first class honours in the Natural Science Tripos, was awarded the

Frank Smart Studentship as the best student of his year and remained at Cambridge to take a PhD, awarded in 1936. He was awarded an ScD in 1951. His professional career started at Long Ashton Research Station in 1934 and he joined ICI in 1936, where he remained until 1963 — first at Jealott's Hill and later at the Akers Laboratories. He returned to academic life in 1963 as Regius Professor of Botany in Glasgow; in 1968 he moved to Cambridge as Professor of Botany, where he stayed until his retirement in 1977. He was awarded an honorary DSc by Hull University in 1978.

Brian's most productive years as a research worker were spent at the Akers Laboratories. Here he collected an active research group and enjoyed close collaboration with organic chemists who shared his interest in natural products. His research planning and management were faultless; he maintained his interest in a problem only as long as the results justified the work involved; he noticed potential developments peripheral to his central theme, but he did not pursue them until he could give them adequate backing; he did not fritter his energy on red herrings. Once he had launched a new line of research, he gave the workers themselves complete freedom to develop it. The result was a happy, well-integrated and purposeful group.

Brian's central interest as the Akers Laboratories was the influence of antibiotics on the balance of fungi in the soil; this involved collecting antibiotics from soil fungi, examining their effects on other fungi and on higher plants and trying to establish whether the same chemicals were produced in soils. Brian was not deterred by the magnitude and complexity of this problem. During the course of this work he noticed that although most of the antibiotics were generally toxic, a few, notably griseofulvin, were more specifically active against fungi and might have a potential in plant chemotherapy. Brian launched a programme to study this possibility some 10 years before the subject became respectable. Griseofulvin was never sucessful as a plant chemotherapeutant, but found a unique place in the treatment of mycoses in man and other animals, a possibility which Brian foresaw some years before the chemical was developed.

The chemical interactions of soil fungi included the activity of parasites as well as saprophytes. Among other parasites he studied the products of *Gibberella fujikuori* and isolated the active chemical, gibberellic acid, in large enough quantities to launch a new area of botanical research. The interactions between fungal parasites and their hosts, particularly as related to the balance of hormones in the plant, remained Brian's central research interest. He pursued these studies at Glasgow and Cambridge with the support of the Agricultural Research Council. The ARC Unit of Developmental Botany was established at Cambridge in 1969 with Brian as honorary director. Here hormone physiology was studied in both healthy and diseased plants.

Brian had less time for research in his university posts but he was known as a tower of strength in his departments and he and his wife, Meg, were untiring in their hospitality to students and to their colleagues.

In addition to research and teaching, Brian was unstinting in the time he would give to the substructure of his science. He was a member of the Agricultural Research Council, twice president of the British Mycological Society, president of the Association of Applied Biologists, the Society of General Microbiology and of the Cambridge Philosophical Society at the time of his death. He was vice-president of the Institute of Biology and served on the council of the Society for Experimental Biology. He also maintained his interest in plant pathology and was one of the chief organisers of the 1st International Congress of Plant Pathology. He was elected a Fellow of the Royal Society in 1958 and served on its Council from 1968 to 1970. He delivered the Leeuwenhoek Lecture in 1966. He was created CBE in 1975.

Brian was never a loquacious man and never pushed himself forward. However, he never refused help and advice when it was requested or needed and what he did say was to the point and well worth listening to. It was probably a measure of his greatness that so many people 'beat a path to his door.' He will be sorely missed by his friends and colleagues and particularly by his family, who must command our deepest sympathy.

S.H. Crowdy

Martin Prestige

MARTIN CALDER PRESTIGE, developmental biologist and Senior Lecturer in Physiology at Edinburgh University, died suddenly on 27 August 1979.

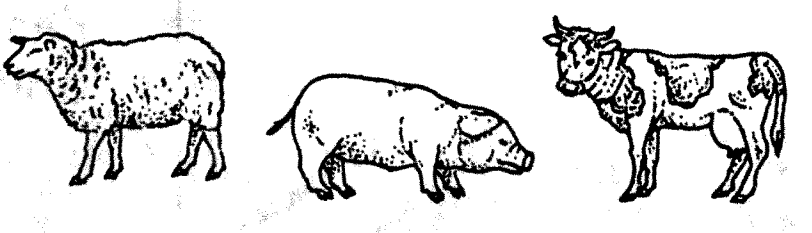
His death, at the early age of 44, removes from the world of developmental neurobiology one of its most incisive minds and able investigators. Educated at Cheltenham College and Trinity College, Cambridge, his basic scientific training was in physiology and led to his being awarded a Michael Foster Studentship. In 1958 he started research, with Patrick Merton, on the occurrence of initial collaterals on kitten motorneurons.

In 1963 Martin joined Arthur Hughes in work on the development of the amphibian spinal cord. This collaboration started in the Anatomy School in Cambridge, continued from 1964 at the Zoology Department in Bristol, and had a great and continuing effect on the general direction of his work. He took his PhD at Bristol in 1967; this was on the development of the nervous system to he hind leg of *Xenopus* tadpoles and it outlined what was to be one of his main research interests. He continued working in Bristol until he moved to Edinburgh as a Lecturer in Physiology in 1968. He loved Edinburgh and remained there, being appointed Senior Lecturer in 1975.

Two main themes run through Martin's work. The first concerns how the nervous system is put together in terms of cell types and cell numbers; and, with a slight modification of emphasis, this changes into the second theme, which concerns how the system is established in terms of adult functional connectivity.

In Martin's early work his friendship with Arthur Hughes shows most clearly, for he started from Hughes' observations on development in *Xenopus* and extended these brilliantly. In a series of papers starting in 1965 he analysed the phenomena of cell death during the development of the spinal cord and its sensory and motor connections. This was beautiful work, highly relevant to ideas that were then beginning to emerge on the role of central-peripheral relationships in the developing nervous system, and it continued up to his death, with a paper currently submitted for publication.

In 1975 the second main theme of Martin's work was illustrated by the publication, with David Willshaw, of their now well-known paper on theoretical aspects of the formation of retinotectal connections. This paper was very important in that it introduced, for the first time, a welcome touch of rigour into the study of how the eye connects with the brain. Up till then there had been, unbelievably, virtually no serious assesssment of the assumptions underlying the various mechanisms that had been proposed to account for the formation of retinotectal connections. Since then there have been several (and more comprehensive) papers on this subject, by others, but the initial credit must go to Prestige and Willshaw.



Martin was also a poet of considerable ability. He had, in his youth, been a mountaineer, and he maintained this interest until his death, in the form of an extensive collection of books on the Himalayas. His first wife, Anne, was killed in a tragic accident. He was married for a second time, to Lucina, in 1972, and their further years in Edinburgh were happy.

In the last year of his life Martin was much troubled by respiratory disability resulting from an illness in youth. Those who knew him over the years will miss him as a friend, as a distinguished scientist, as an inspiration to his colleagues and as an outstanding example of how to behave in the face of adversity.

DEVELOPMENTS IN ANIMAL AND VETERINARY SCIENCES

Volume 5

Physiology and Control of Parturition in Domestic Animals

F. ELLENDORFF, M. TAVERNE, *and* D. SMIDT (editors)

Comprising the proceedings of a symposium held at Mariensee, West Germany, this book provides an up-to-date account of the latest research into the physiology of fetal and maternal control of parturition in domestic animals.

1979 xii + 348 pages US $73.25/Dfl. 150.00
ISBN 0-444-41808-3

Volume 4

Social Structure in Farm Animals

G. J. SYME *and* L. A. SYME

For those working in animal production and veterinary science, here is the first monograph devoted entirely to applied studies of the social behaviour of cattle, pigs, chickens, goats, horses and deer.

1979 x + 200 pages US $39.00/Dfl. 80.00
ISBN 0-444-41769-9

Volume 3

Bacterial Infection and Immunity in Domestic Animals

J. P. WOOLCOCK

An up-to-date review of the important new advances made in the study of the mechanisms of infective disease.

1979 xii + 256 pages US $65.75/Dfl. 135.00
ISBN 0-444-41768-0

Volume 2

Ethology of Free-Ranging Domestic Animals

G. W. ARNOLD *and* M. L. DUDZIŃSKI

A detailed study of the various factors influencing the maintenance, social, mating and maternal behaviour of free-ranging sheep, goats, cattle and horses, this book demonstrates the behavioural interactions between the animal and its environment, including man.

1979 xii + 198 pages US $51.25/Dfl. 105.00
ISBN 0-444-41700-1

Volume 1

Guide Dogs for the Blind: Their Selection, Development and Training

APPOINTMENTS VACANT

HOUGHTON POULTRY
RESEARCH STATION
SCIENTIFIC OFFICER
HISTOLOGY

A vacancy exists in the Histology Section for a scientific officer to assist with the provision of routine histological services and the performance and development of specialised techniques.

Applicants must have a degree, HNC or equivalent qualification with several years' experience in histology.

The appointment will be to the Scientific Officer grade (£3,289 × 12 to £5,085) which will be revised to (£3,591 × 10 to £5,486) with effect from 1st January 1980 with a starting salary depending upon qualifications and experience. Non-contributory superannuation scheme.

Further particulars and application forms from the Station Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs. PE17 2DA. Closing date for application is 20th December 1979. 3852(A)

THE UNIVERSITY OF ADELAIDE
South Australia
SENIOR RESEARCH OFFICER

to work on a project on transformation of human epithelial cells by Herpes simplex virus. Details may be obtained from Dr. M A Stanley in the University. Salary $A15,786 × 7 — $20,738 (N.H. & M.R.C.), available for up to 3 years.

Applications in duplicate, giving personal and academic particulars plus names and addresses of two or three referees to reach the Registrar of the University, G.P.O., Box 498, Adelaide, South Australia 5001 by *21 December 1979*. *Senior Research Officer* for 3 years to work on organization and control of human collagen genes. Salary $A15,786 × 7 — $20,738 (N.H. & M.R.C.). For details write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or The Registrar of the University, with whom applications close as soon as possible. 3855(A)

UNIVERSITY OF LONDON
Institute of Psychiatry
DEPARTMENT OF NEUROLOGY
RESEARCH ASSISTANT

Applications are requested from recently qualified graduates in pharmacology, biochemistry or related disciplines for a project investigating the effects of long-term neuroleptic administration on cerebral dopamine mechanisms.

The post is tenable for 2 years, renewable annually.

Salary on Research Scale 1B. — £3,775 to £4,333 plus £740 London weighting.

Application forms can be obtained from: The Secretary, Institute of Psychiatry, De Crespigny Park, London SE5 8AF. 3848(A)

UNIVERSITY OF STIRLING
DEPARTMENT OF EARTH & ENVIRONMENTAL SCIENCE
RESEARCH ASSISTANT

A Research Assistant is required from 1 March 1980 for a period of 2 years, to work on an NERC-funded research programme monitoring temperature regimes in the inter-tidal mudflats of the Forth Estuary. Applications are invited from graduates with good honours degrees in Environmental Science, Biology, or Geography who have at least 2 years postgraduate research experience. Preference will be given to applicants with practical experience in environmental monitoring and/or environmental data handling. Starting salary will be on the first point of the Research Assistant 1B Scale, at £3,775.

Applications, giving the names of 2 referees should be submitted by 21 December 1979, to The University Secretary (N), University of Stirling, Stirling FK9 4LA, from whom further particulars may be obtained. 3839(A)

Assistant Fisheries Officer

£6,003 — £6,426 p.a.

This post is in the Authority's Amenity, Fisheries and Recreation Department based in Central Leeds.

The successful applicant will be responsible to the Fisheries Officer and will assist him in relation to fisheries management advice and fisheries policies and especially in dealing with the issue of statutory consents under Fisheries legislation. Particularly he/she will be responsible for the collection, collation and assessment of scientific reports and information relating to fisheries functions and the production of fisheries reports for the Authority's committees and publications.

Applicants must possess a degree in a Biological Science and have at least two years post graduate experience. Experience of information retrieval and statistics would be an advantage.

Removal expenses and disturbance allowances will be available in approved cases and appropriate car user allowance is payable.

Application forms may be obtained from the Regional Personnel Officer, Yorkshire Water Authority, 67 Albion Street, Leeds, LS1 5AA (Tel. Leeds 448201 Ext. 269) to whom they should be returned by 10 December 1979 quoting Ref. RN 719.

3833(A)

Yorkshire Water

INSTITUTE OF TERRESTRIAL ECOLOGY
SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER

The Institute has a vacancy for a Scientific Officer/Higher Scientific Officer within a team engaged in genetic evaluation and selection of young conifers and broad-leaved trees. Current work involves field and laboratory studies on competition and frost hardiness and will include the collection, propagation and evaluation of broad-leaved trees. There will be an opportunity to contribute to new lines of research on physiological genetics of trees. The post will be based at Bush Estate, Penicuik, near Edinburgh.

Qualifications: Candidates should have a good honours degree or equivalent in applied plant science or forestry and preferably some practical experience. Candidates for Higher Scientific Officer should have at least two years post graduate experience for those with an Honours degree or five years experience for those with HNC/HND.

Salary and conditions of service: The salary will be within the following scales: SO £3,289 to £5,085; £3,591 to £5,486 revised rate from 1.1.80. HSO £4,727 to £6,211; £5,097 to £6,737 revised rate from 1.1.80.

Up to 22 days annual leave plus 10½ days public and privilege holidays. Starting pay according to age, qualifications and experience. There is a non-contributory superannuation scheme.

The Natural Environment Research Council is not a Government Department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from: Establishments Section, Institute of Terrestrial Ecology, 68 Hills Road, Cambridge, CB2 1LA. Telephone: (0223) 69745.

Closing date for completed applications is 14 December, 1979. Reference 124.
Natural Environment Research Council. 3814(A)

THE POLYTECHNIC OF WALES Department of Science, Anaerobi Digestion Research Technician (Salar £3,894) required to join in a projec investigating factors affecting methan production during the anaerobic digestio of animal wastes. Applicants should have degree or equivalent in a field whic includes biochemistry and microbiology and a good working knowledge o techniques in analytical chemistry an microbiology. The post is of three years duration and is funded by the SRC. Furthe particulars from: Asst. Director (Staffing) The Polytechnic of Wales, Pontypridd Mid Glamorgan, CF37 1DL. Telephone Pontypridd (0443) 405133, Ext. 202 Closing date: 17 December 1979. 3842(A)

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
TECHNICIAN POSTS IN FOOD SCIENCE

Grade 4 in food chemistry laboratorie Experienced in chemistry teachin laboratories essential. C & G Scien Laboratory Technicians' Certificate equivalent desirable. Salary on scale £3,4 to £3,950 p.a. (under review) plus Lond weighting £780 p.a.

Trainee to assist with classes in foo science. Day release available for approved qualification. GCE 'O' level chemistry or physics or biology require Salary (under review) depending on age scale £1,834 to £2,553 p.a. plus Lond weighting of £780 p.a.

Applications, giving details education, age, and other experience, a names of two referees, to the Colle Secretary, Queen Elizabeth Colleg Campden Hill Road, London W8 7AH. 3832(A)

PROGRAM DIRECTOR OF PHYSICAL AND CHEMICAL OCEANOGRAPHIC DATA FACILITY AT SCRIPPS INSTITUTION OF OCEANOGRAPHY, OCEAN RESEARCH DIVISION

The Facility constitutes one of the most advanced groups specializing in the collection and processing of physical and chemical measurements in the ocean. Programs carried out encompass Institutional, National and International oceanographic programs. The Program Director of the Facility is responsible for the guidance of this group as well as for directing the development and introduction of new oceanographic techniques, instrumentation, and data processing procedures. Participation in the scientific endeavors of the various programs is encouraged. At present the Facility employs forty people. Academic Administrator salary range $30,000 to $42,000. For further information, address Search Committee, P.A.C.O.D.F. C/O Chairman, Ocean Research Division, A-020, Scripps Institution of Oceanography, La Jolla, CA 92093. The University of California is an Equal Opportunity/Affirmative Action Employer. W572(A)

CANCER RESEARCH UNIT, University of Western Ontario, London, Ontario. Positions are available for staff at the Assistant or Associate Professor level (non-tenure track) and for postdoctoral fellows and graduate students. Research is focussed on the areas of cellular and viral DNA replication, nucleic acid metabolism in eukaryotic cells, mRNA cloning, and mechanisms of cell transformation.

The unit is well funded by the National Cancer Institute of Canada and is affiliated with the Department of Biochemistry and the Department of Microbiology and Immunology in the Medical School of the University.

Candidates for a staff position should submit a curriculum vitae, statement of research interests, and the names of three referees to Dr. David T. Denhardt, c/o The Administrative Secretary, Cancer Research Unit, University of Western Ontario, London, Ontario N6A 5B7, Canada. Students should apply for admission through the above mentioned Departments. W544(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

UNIVERSITY OF WÜRZBURG

DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY

German Federal Republic

Applications are invited for POSTDOCTORAL FELLOW POSITIONS (Wissenschaftliche Mitarbeiter, BAT IIa)

for two years or longer, which will become vacant on March 1, 1980. The salary will be about DM42,000 per annum. German citizenship is not a prerequisite. Candidates must have a PhD in Biochemistry and an active research interest in Molecular Endocrinology and Isolation and Characterisation of Membrane Proteins.

Applications with a curriculum vitae, qualifications and grades and the names of two referees should be sent until January 1, 1980 to Ernst J M Helmreich, Professor and Chairman, 8700 Würzburg, FRG, Koellikerstrasse 2, Tel: 0931/31745 und 46. W562(A)

QUEEN ELIZABETH COLLEGE

Kensington

(University of London)

ELECTRON MICROSCOPE TECHNICIAN, Grade 5

required in the Microbiology Department to run a service used by the Departments of Microbiology, Physiology and Biochemistry.

Equipment is an AEI EM6B electron microscope and a JEOL 25/S11 scanning electron microscope is to be installed shortly. The technician will be expected to operate and maintain the microscope and advise staff and students in the techniques, and will need the appropriate qualifications. Salary on scale £3,700 to £4,320 p.a. (under review) plus London weighting £780 p.a.

Applications giving a curriculum vitae and names of two referees to the College Secretary, Queen Elizabeth College, Campden Hill Road, London, W8 7AH. 3830(A)

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF PSYCHOLOGY

RESEARCH ASSISTANT: ANIMAL BEHAVIOUR

Applications are invited for a post of research assistant to work with A Whiten and J Graves on a continuing SRC Project "The Development of Parent-Offspring Relationships in the Herring Gull". Applicants should have a relevant first degree, and preference will be given to those with experience of behavioural, ecological and/or ornithological study. The successful applicant will conduct observational and experimental research on this topic on the Isle of May and Holy Isle, off Arran, and subsequently collaborate in analysis and publication.

The appointment must begin in March 1980 or earlier, and may last for up to 2½ years. Starting salary scale within range £3,775 to £4,910 according to age and qualifications, plus FSSU/USS.

Applications (two copies preferably in typescript) with the names of three referees should be lodged by 14th December 1979 with the Establishments Officer, The University, College Gate, St Andrews, Fife, from whom further particulars may be obtained. 3840(A)

CSIRO AUSTRALIA

Post Doctoral Research Fellow (2 Positions)

Fuel Geoscience Unit

North Ryde NSW

CSIRO has a broad charter of research into primary and secondary industry areas. The Organization has approximately 7000 employees — 2400 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

GENERAL: The Fuel Geoscience Unit conducts research relevant to exploration for the fossil fuels — coal, petroleum, natural gas and oil shale — and to their assessment and extraction.

FIELD: Coal Utilisation — Position number 604/168

DUTIES: To initiate and conduct, within a team, fundamental research related to conversion of coals to liquid fuels, with special emphasis on coal hydrogenation. The appointee will be required to use both microscopic and chemical techniques to study the properties of coals and of products obtained from coals after treatment.

QUALIFICATIONS: A PhD or equivalent qualifications together with experience in the field of either coal chemistry or coal petrology.

FIELD: Coal Mine Geology — Position number 604/169

DUTIES: To initiate and conduct research aimed at generating information relevant to coal mining prior to the construction of mine openings. The appointee will be, or should become, familiar with geological factors of importance in open and underground coal mining and will be required to apply some of the tehniques of sedimentary petrology (including microscopy) and engineering geology to studies of coal seams, overburdens and inter-seam sediments.

QUALIFICATIONS: A PhD or equivalent qualifications in a relevant area of geology. Experience appropriate to the duties above, especially concerning the significance of the physical and chemical properties of coals and rocks to mining practice would be an advantage.

SALARY: Appointment for both positions will be within the range of Research Scientist/Senior Research Scientist: $A15,916 — $A23,122 p.a.

TENURE: Three years with the possibility of extension.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting the appropriate reference number(s) should reach The Personnel Officer, Australian Scientific Liaison Office, 10-16 Maltravers St, London WC2R 3EH by 28th December, 1979. Applications in USA and Canada should be sent to The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue NW, Washington DC 20036. 3834(A)

University of Basle

Faculty of Science

In connection with the reorganisation of the Department of Zoology applications are invited for the position of

PROFESSOR (full professor)

The position will become available at the end of 1980.

Experience is desired in one of the following fields: ecological ethology, morphology including electron microscopy.

Duties include general teaching in zoology and collaboration in research and teaching with special emphasis on ecological aspects.

Applications stating publications, teaching experience, curriculum vitae etc. should be submitted until January 1980.

Address: Dekanat der Philosophisch-Naturwissenschaftlichen Fakultät der Universität Basel, Klingelbergstrasse 70, CH-4056 Basel.

No further application is required for those who already have applied for another, previously advertised position in the Department of Zoology. Complementary material may be submitted, however. W566(A)

The Wellcome Research Laboratories Beckenham

Wellcome

Biochemist £6,000-£11,000*

A Biochemist is required in the Department of Parasitology to join a team studying electron transport systems and related topics in parasitic protozoa and helminths, with the aim of more effective chemotherapy of the diseases caused by these organisms.

Candidates should be familiar with those techniques used to study electron transport processes in mitochondrial preparations, particularly spectrophotometry and physicochemical methods. A PhD in biochemistry is essential and the successful candidate will have either recently completed the degree or have a few years' post-doctoral experience in this area of biochemistry. *Salary, dependent on age and experience, will be within the range £6,000 to £11,000.

The Laboratories are situated in pleasant parkland surroundings within easy reach of Central London and conditions of employment are excellent and include subsidised canteen, pension scheme, 4 weeks' holiday, relocation expenses where appropriate and sports and social facilities.

For an application form please write, giving brief details of background and experience, to

the Personnel Manager,
Wellcome Research Laboratories,
Langley Court,
Beckenham, Kent BR3 3BS.

1979

3827(A)

THE DEPARTMENT OF BIOLOGICAL SCIENCES OF HUNTER COLLEGE CUNY

welcomes applicants for a tenure-track faculty position.
Applicants with expertise in any of the following areas will be favored: ecology, physiological ecology (plant or animal), population biology/evolution, and plant physiology/virology. The candidate should have post-doctoral experience and is expected to establish a research program in addition to teaching duties.
Send curriculum vitae, names of 3 references & a statement of career goals to:

DR C CECCARINI
CHAIRPERSON, SEARCH COMMITTEE
DEPT OF BIOLOGICAL SCIENCES
HUNTER COLLEGE OF CUNY
695 PARK AVENUE
NEW YORK, NY 10021

An equal opportunity/affirmative action employer. **W573(A)**

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSICS

RESEARCH ASSISTANT

The University of Leicester is embarking on a project — supported by the Royal Observatory, Edinburgh — to develop focal plane instrumentation for the 3.4m United Kingdom Infra Red Telescope (UKIRT) in Hawaii. A post exists for a research assistant to join the project, firstly to investigate applications of multi-element CID imaging detectors in infra-red astronomy; secondly to develop instrumentation for UKIRT using these devices, and thirdly to take part in astronomical observations using UKIRT.

Salary will be within the range £4,333 to £5,488 depending upon qualification and experience. Superannuation is under USS conditions.

Applications, together with the names and addresses of two referees, and a curriculum vitae, should be sent to Professor K A Pounds, Department of Physics, University of Leicester, LE1 7RH by December 17th 1979. Further particulars about the project are available on request. 3843(A)

UNIVERSITY COLLEGE LONDON

SCIENCE RESEARCH COUNCIL COLLABORATIVE PROJECT ON

ASTRONOMICAL SPECTRA

The Science Research Council has established a Collaborative Computational Project concerned with the Analysis of Astronomical Spectra. Research workers at the following institutions will be participating in the project: Universities of Belfast, Cambridge, Cardiff, London, Oxford and St. Andrews, the Royal Greenwich Observatory and the Royal Observatory Edinburgh.

The work will be concerned with stellar atmosphere theory (maintaining a library of well-documented computer programs, developing new techniques, maintaining collaboration with research groups at home and abroad, and collaboration with groups studying relevant physical processes) and with the interpretation of other astronomical spectra. A Research Assistant will be appointed to work on the Project in the Department of Physics and Astronomy, University College London, and will be expected to maintain close contact with the Theory and Computation Division at the Science Research Council's Daresbury Laboratory and with the other participating institutions. Applicants should have a PhD or equivalent qualification, extensive experience of computational work, and preferably expert knowledge of stellar atmosphere theory or other aspects of radiative transfer theory.

The starting salary is in the range £4,333 to £5,199 p.a. plus £740 p.a. London Allowance. Applications should be addressed to Professor M J Seaton FRS, Dept of Physics and Astronomy, University College London, Gower St, London WC1E 6BT, and should be received by 1 January 1980. 3838(A)

McGILL UNIVERSITY

POSTDOCTORAL POSITION: CELL BIOLOGY

Applications are invited for a postdoctoral position for 2 years. The post is for research in the regulation of DNA replication and functions of tumor antigens in mammalian cells. It is available April 1, 1980. Previous experience in cell culture is required and training in molecular biology, animal virology or somatic cell genetics would be helpful. The research group includes other postdoctoral fellows and graduate students. Opportunities are available for interaction with other groups interested in nucleic acid research.

Applications with curriculum vitae and names of reference to: Dr Roger Hand, McGill Cancer Centre, 3655 Drummond, Montreal, Que. H3G 1Y6. W575(A)

UNIVERSITY OF RHODE ISLAND

Narragansett, Rhode Island 02882

MARINE RESEARCH ASSOCIATE II or III

Responsible for studies in phytoplankton and zooplankton production, species composition and abundance and other aspects of plankton ecology in enclosed ecosystems affected by low level chronic pollutants or other perturbations; supervise technical personnel, sampling program, data acquisition and analysis, scholarly writing and independent research. PhD, and experience in plankton required.

Submit résumé and the names of three references by December 31, 1979 to: Dr Candace Oviatt, MERL Graduate School of Oceanography. An Affirmative Action/Equal Opportunity Employer. W571(A)

IMPERIAL COLLEGE (University of London) ENHANCED OIL RECOVERY RESEARCH

Applications are invited for post-doctoral research posts (SRC sponsored) tenable for up to three years for the study of: 1) the behaviour of emulsions in reservoir rocks, 2) capillary effects in the enhanced recovery of oil from reservoir rocks.

The work is of fundamental importance to oil recovery processes and requires an appreciation of fluid-surface interfacial phenomena and of porous media.

The usual SRC conditions apply, with a starting salary within the range of research and analogous staff, grade 1A, £4,333 to £7,521 (under review) plus £740 London Allowance, and the posts carry USS benefits. Initial placing dependent on age, qualifications and experience.

Enquiries and applications (giving curriculum vitae and the names of two referees) to Dr R A Dawe, Mineral Resources Engineering Department, Imperial College, London SW7 2BP.

A number of studentships for study to PhD are also available. 3837(A)

CANBERRA COLLEGE OF ADVANCED EDUCATION

SCHOOL OF APPLIED SCIENCE

COLLEGE FELLOW IN LIFE SCIENCES (Ref. No. 79/2177)

The College Council has reviewed recently the structure of the School of Applied Science and has decided that the importance attaching to the teaching of the Life Sciences in the College is such as to justify the establishment of a position of College Fellow at professorial level.

Applications are invited from persons with academic and professional qualifications and experience appropriate to such a senior academic post in a School which is concerned with the teaching of applied science in its broadest sense. The School of Applied Science has developed degree and diploma programmes of an inter-disciplinary nature in Land Science Park Management, Resource Management, Natural Resources, Ecology Human Biology, Medical Technology Nursing Science, Community Health Nursing, Applied Geology, Cartography Physics and Electronics, Material Conservation, Resource Management Recreation Planning, and Electronics Planned development for the future includes the establishment of basic and post-basic courses in Nursing and in other health-related fields. The College has an established reputation in the community for the variety and strength of its vocational course programmes.

The appointee will be required to provide academic leadership in the broad area of the Life Sciences within the School, to play a significant role in the academic development of the School as a whole, and to assist in its day-to-day administration. The appointee will also be required to carry some teaching duties in his/her own special area of expertise.

Salary: $A34,119 per annum. Assistance with housing will be provided for a person moving to Canberra to take up appointment. Fares for the appointee and family and reasonable removal costs will be paid.

Applications should give personal details, particulars of qualifications, experience, previous appointments, present position, telephone number during business hours and the names and addresses of three referees. Applications quoting reference number are required by 15 January 1980 and should be addressed to: The Registrar, Canberra College of Advanced Education, PO Box 1 Belconnen Act 2616, Australia, and a copy to the Association of Commonwealth Universities (Appts), 36 Gordon Square London WC1H 0PF. 3820(A)

Experimental Officer

A vacancy exists for a person with a first degree in Biology, Agriculture or related subject to lead a small team which investigates the potential of new seed treatments for the control of cereal diseases. The job holder, who will respond to the Senior Cereal Pathologist, should have the ability to plan and conduct experimental programmes in the glasshouse and field, and have a good general knowledge of plant pathology and chemistry.

Applicants should have some experience of crop protection research, and previous work on the treatment or testing of seeds would be particularly valuable.

Jealott's Hill is the chemical and biological research centre for the crop protection interest of ICI. It is situated in open country 30 miles west of London, between Bracknell and Maidenhead. We offer competitive salaries and fringe benefits including membership of the ICI Profit Sharing and Pension Fund. Coaches run between Jealott's Hill, Bracknell and Maidenhead.

If you are interested in this vacancy please write or telephone for an application to:

Mr S R Stephenson, Personnel Officer, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell. Telephone 24701

ICI Plant Protection Division

(University of London)
COURTAULD INSTITUTE OF BIOCHEMISTRY

A POSTDOCTORAL and also a GRADUATE RESEARCH ASSISTANT

e required from 2nd January 1980 to join group interested in the mechanism of tion of the Carcinogenic N-introso mpounds.

Candidates should have degree alifications in Biochemistry (or possibly emistry) and be interested in developing immunological approach dioimmunoassay and immunocytology) the study of carcinogen-nucleic acid eraction. These positions are funded by Cancer Research Campaign for a fixed riod.

Starting salaries, according to age, alifications and experience, £5,073 to 228 per annum (Postdoctoral) and 515 to £5,361 per annum (Graduate) lusive of London Allowance.

Applications together with names and dresses of 2 referees to Dr P F Swann, urtuld Institute of Biochemistry, The ddlesex Hospital Medical School, ndon. W1P 5PR. 3847(A)

THE UNIVERSITY OF AUCKLAND
New Zealand

BIOCHEMISTRY
Lectureship

Applicants should have a first degree in biochemistry or chemistry and suitable postgraduate experience in biochemistry. Preference will be given to candidates who have completed a period of postdoctoral research. The successful applicant will be required to teach biochemistry to undergraduates, to give suitable advanced courses at the masters level and to supervise laboratory work by research students. Commencing salary will be determined in accordance with qualifications and experience within the range NZ$13,722 to $16,861 per annum.

Conditions of appointment and Method of Application are available from the Academic Appointments Office, University of Auckland, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications, in accordance with 'Method of Application' should be forwarded as soon as possible but not later than 29 February, 1980. 3829(A)

Public Service Canada / Fonction publique Canada

Open to both men and women

Fisheries and Oceans Canada
Marine Ecology Laboratory
Dartmouth, Nova Scotia

RESEARCH SCIENTISTS

Salary: Up to $36,428

The Bedford Institute of Oceanography located in Nova Scotia, Canada, one of the world's largest Oceanographic Institutes, has need for Research Scientists in the following specialities:

Microbiologist (119-291-011)
Ref. No.: 79-PSCH-DFO-SE-6073

Conducts research on micro-organisms in the marine environment with emphasis on nutrition, growth, bio-energetics, and on the role of micro-organisms in the tropic dynamics of the marine ecosystem.

Qualifications
PhD in microbiology, oceanography or similar field. Research experience in ecology or marine micro-organisms; ability to conduct research at sea and to plan and conduct studies of structure and function of the marine phytoplankton community.

Physical Oceanographer (119-291-002)
Ref.No.: 79-PSCH-DFO-SE-6072

Plans and conducts research on the physical processes which determine biological productivity with emphasis on continental shelfs. The research involves participation in work at sea as well as extensive use of numerial simulation and analysis techniques.

Qualifications
PhD or equivalent research experience in physical oceanography, physics, applied mathematics or related field. Research experience and demonstrated capacity to make relevant original contributions.

Zooplanktologist (119-261-002)
Ref.No.: 79-PSCH-DFO-SE-6074

Conducts research on marine secondary production processes among representative groups in the pelagic community, with the objective of developing biochemical indices of resource transfer and energy utilization for use in food chain modelling and production studies.

Qualifications
PhD or equivalent research experience in marine biology, oceanography or biochemistry with a sound general knowledge of ecology and invertebrate zoology especially marine zooplankton. Ability to conduct research at sea.

Language Requirements
Knowledge of English is essential for all these positions.

"Additional job information is available by writing to the address below;
Toute information relative à ce concours est disponible en français et peut être obtenue en écrivant à l'adresse suivante".

How to apply
Send your application form and/or résumé to:
Mrs E Cruickshank (902) 426-2169
Public Service Commission of Canada
4th Floor, 5161 George Street
Halifax, Nova Scotia B3J 1M8
Closing Date: December 28, 1979 W565(A)

Please quote the applicable reference number at all times.

RESEARCH SCIENTIST

An opportunity to gain valuable experience in the design and synthesis of fluorinated bioactive agents.

. . . with one of the world's most highly regarded pharmaceutical companies. This two-year postdoctoral appointment at our Rahway, New Jersey laboratories requires a highly motivated person with a PhD in chemistry to participate in research in the design and synthesis of fluorinated bioactive molecules including agents to interfere with the biosynthesis, release, degradation, or action of neurotransmitters. The appointment carries a first year stipend of $18,000.

To explore, this opportunity, please send resume to Mrs. S. R. Jenkins,

MERCK & CO., INC.
P.O. Box 2000, Rahway, NJ 07065

An equal opportunity employer m/f
W569(A)

UMIST
Department of Ophthalmic Optics
RESEARCH STUDENTSHIP

A suitably qualified graduate is needed to carry out research on the interaction of the eye with optical instruments, particularly sighting telescopes, and to investigate the effect of such factors as ocular accommodation and aberration on the overall performance achieved. The stipend is at normal Research Council rates and the project will initially run for a period of one year; the successful candidate will register for an MSc degree.

Further details may be obtained from Dr W N Charman, Ophthalmic Optics, UMIST, PO Box 88, Manchester M60 1QD. 3836(F)

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

LECTURER: MOLECULAR GENETICS

Applications are invited for the post of Lecturer, in Molecular Genetics, in The School of Biological Sciences. Applicants should have research interests in molecular genetics and experience in modern methods of gene manipulation and DNA biochemistry. The salary will be within the scale £4,333 to £8,992 (under review) with superannuation benefits.

Application forms and further particulars can be obtained from the Assistant Secretary of Science, Science Office (E), Sussex House, University of Sussex, Falmer, Brighton BN1 9RH, to whom applications (8 copies) should be sent by 14th January 1980. 3822(A)

UNIVERSITY COLLEGE OF NORTH WALES
Bangor

RESEARCH OFFICER IN ORGANIC CHEMISTRY

Applications are invited for the above one year SRC-supported postdoctoral post to work on strain-accelerated elimination reaction, in collaboration with Professor C J M Stirling, to whom informal enquiries may be made. (Bangor 51151, Extension 223.)

Salary will be in the range £4,333 to £4,910 per annum (under review).

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of two referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2UW as soon as possible. 3845(A)

QUEEN MARY COLLEGE
(University of London)

GEOLOGICAL SCIENCES DEPARTMENT

Postgraduate or postdoctoral
RESEARCH ASSISTANT

required for one year to assist work on the influence of fabrics on the transference of water-soluble ions through soils, a project supported by I.C.I.

Candidates should have a degree in geology, chemistry, geochemistry, geotechnology or physics.

Salary, according to qualifications and experience, in range (under review) £3,775 to £4,910 p.a., plus £740 London Allowance.

Please apply, giving details of age, qualifications, experience and two referees, to The Secretary, (N) Queen Mary College, Mile End Road, London E1 4NS, by 14 December. 3849(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF COMMUNITY MEDICINE

RESEARCH ASSISTANT

Applications are invited for the post of graduate research assistant to work on Epidemiological studies in the fields of diabetes and other chronic diseases. The post is tenable for three years and applicants should have a higher degree or equivalent experience in epidemiology, demography or medical statistics. Starting salary up to £5,940 per annum according to age, qualifications and experience.

For further details contact: Dr J.H. Fuller, Department of Community Medicine, Horace Joules Hall, Central Middlesex Hospital, London NW10 7NS, to whom applications should be sent by 21 December, 1979. 3831(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CARDIOVASCULAR MEDICINE

Applications are invited for the post of

RESEARCH STUDENT

from persons with a good honours degree in Biochemistry, Physiology or related subjects to study aspects of the contractile and regulatory proteins of the human myocardium in normal and pathological conditions. The post which is supported by the British Heart Foundation is available from October 1979 and is funded for 3 years.

Applicants will be expected to register for the degree of PhD.

Further details can be obtained from Dr Peter Cummins, Department of Cardiovascular Medicine, Clinical Research Block, Queen Elizabeth Hospital, University of Birmingham, Birmingham B15 2TH, to whom applications, together with curriculum vitae and names of two referees should be returned not later than Friday 14th December. 3826(A)

TECHNICIAN — BIOLOGY
£3400 to £3800
THE CITY OF LONDON POLYTECHNIC

invites applications for a vacant post of Technician 2B in the Department of Biological Sciences. This Department is located at Calcutta House, Old Castle Street, London E1 close to Aldgate and Aldgate East Underground stations.

The successful candidate will assist the Biochemistry Technician Grade 6 in servicing practical classes and carry out other general duties.

Normal background experience required is 3-5 years (including training period) and minimum qualifications will be ONC OND, 2 'A' levels, or C & G.

Good conditions of service include 37 hour week, 18 days annual leave (rising to 21 with service), sick pay, contributory pension scheme. The Polytechnic offers positive encouragement to staff wishing to study for relevant qualifications.

Salary on a scale from £3462 to £3864 which will increase in April 1980.

For an application form and job description please write to the Staff Records Officer, City of London Polytechnic, 117 Houndsditch, London EC3A 7BU. Please quote reference 79/144. 3816(A)

NORTHWESTERN UNIVERSITY
Geological Sciences

Seizing an opportunity to strengthen the Department, the Department plans to recruit five faculty over the next two years. Two or three of the following positions are to be filled in 1980:

SENIOR PROFESSOR
(to become William Deering Professor on retirement of L L Sloss in 1981) to provide leadership in broad Crustal Evolution Program; global stratigraphy and sedimentation or some analogous fields.

GEOCHEMIST
(probably Assistant or Associate Professor) with strong kinetics-thermodynamics background and interests in chemical and physical interactions among surface waters, sediments, and atmosphere.

Solid Earth **GEOPHYSICIST** (Assistant Professor): theoretical methodology would be most compatible with general departmental research, but search not limited to theorists.

Send nominations, applications, and inquiries to E H Timothy Whitten, Chairman, Department of Geological Sciences, Northwestern University, Evanston, Illinois 60201, USA.

An Equal-Opportunity/Affirmative-Action Employer. W576(A)

UNIVERSITY OF DUNDEE
DEPARTMENT OF PATHOLOGY
Applications are invited for the post of LECTURER (CLINICAL OR NON-CLINICAL)

with duties in the Section of Immunopathology.

Applicants should have wide experience in immunopathology, with particular interests in humoral mechanisms and human immunopathology.

Duties will involve participation in the diagnostic service, teaching (intercalated-degree medical students and supervision of postgraduates), and research.

Informal enquiries should be made to Professor J. Swanson Beck (telephone 0382 60111 ext. 2169).

Further particulars can be obtained from The Secretary, The University, Dundee DD1 4HN to whom applications (eight copies) giving details of qualifications, experience and names of three professional referees should be submitted by 22nd December 1979. Please quote Reference EST/97/79]. 3835(A)

UNIVERSITY OF EDINBURGH
CENTRE FOR REPRODUCTIVE BIOLOGY
DEPARTMENT OBSTETRICS AND GYNAECOLOGY
LECTURER (NON-CLINICAL)

Applications are invited for the above post in the Department of Obstetrics and Gynaecology. Preference will be given to those who have experience in the biochemistry of reproduction. The successful candidate will be expected to conduct research in reproductive endocrinology and to participate in the teaching of undergraduate and supervision of postgraduate students. There are excellent facilities for collaborative work with clinicians in the Royal Infirmary and scientists in the MRC Unit of Reproductive Biology.

Salary on the scale £4,333 to £8,992 per annum. USS Superannuation.

Enquiries may be addressed to Professor D T Baird, Department of Obstetrics and Gynaecology, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh, (031 229 2575)

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (8 copies) including curriculum vitae and the names and addresses of three referees should be lodged not later than 21st December 1979. Please quote Reference 1085. 3846(A)

Food Scientists

London Area

Our client is a major British food company, with a diversified range of high quality products. A major further diversification programme is now under way and this has led to a requirement for the following key managers.

Fermentation Manager

– to lead a team of microbiologists working on a range of fermentation processes.

Project Manager
Food Products

– to identify and develop new food ingredients with the company's expansion criteria.

In both cases, a Ph.D. in a biological or chemical science would be desirable. Experience in a similar or related field in a scientific managerial role will be necessary.

Generous salaries and fringe benefits would be offered.

Candidates (male or female) should submit full résumés, which will be treated in full confidence, to the consultants handling the appointment.

Anthony Whitmee & Associates,
86 WIMPOLE STREET, LONDON W1M 7DB

SCIENTIST
(PhD or equivalent)

with biomedical background and at least five years' research experience, required for challenging post in an organisation concerned with promoting alternatives to laboratory animals. Salary according to age and experience.

For further details apply to FRAME (Fund for the Replacement of Animals in Medical Experiments) 312a Worple Road London SW20 8QU. 3853(A)

UNIVERSITY
OF ALASKA
MICROBIAL ECOLOGIST

The Institute of Marine Science at the University of Alaska will fill at the rank of assistant professor a tenure-track position in one of the several areas related to marine microbial processes.

The successful applicant will provide evidence of a strong background in fundamentals and of experience related to natural processes. Participation in interdisciplinary studies is encouraged. A letter of application, curriculum vitae, and the names of three references should be sent to Dr Vera Alexander, Acting Director, Institute of Marine Science, University of Alaska, Fairbanks.

The University of Alaska is an Affirmative Action/Equal Opportunity Employer. Closing date; January 6, 1980. W577(A)

UNIVERSITY
OF LONDON
KING'S COLLEGE

BIOCHEMIST OR
PHARMACOLOGIST

Research Assistant required at postgraduate or postdoctoral level to work on mechanism of action of nicotine-like drugs. Appointment at appropriate position on University scale.

Knowledge of membrane or lipid biochemistry an advantage.

Please apply in writing to Dr J M Littleton, Department of Pharmacology, King's College, London WC2R 2LS. 3817(A)

UNIVERSITY
OF OXFORD
MRC MOLECULAR
HAEMATOLOGY UNIT

Applications are invited for a
POST-DOCTORAL
RESEARCH ASSOCIATE

to join a group working on human haemoglobin gene expression.

Candidates preferably should have had experience in the use of re-combinant DNA techniques or chromatin transcription systems. Salary in the range £3,775 to £6,355 (under review), according to age and experience.

Applications, together with curriculum vitae and the names of three referees, should reach Professor D J Weatherall, Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Headington, Oxford OX3 9DU, by: 31.12.79. 3821(A)

The Department of Pathology at the University of Pittsburgh School of Medicine wishes to recruit a member for its Division of Experimental Pathology. The position will entail research and teaching to medical students and to graduate students. There are ample clinical opportunities for research programs needing them. The major areas of interest in the Division are immunology and tumor biology.

The level of academic appointment will be commensurate with the candidate's qualifications.

Reply with Curriculum vitae to: Thomas J. Gill, MD, University of Pittsburgh School of Medicine, Department of Pathology, Room 716, Scaife Hall, Pittsburgh, PA 15261.

An equal opportunity/affirmative action employer. W495(A)

UNIVERSITY OF PENNSYLVANIA
POSTDOCTORAL FELLOW

to study Control of Gene Expression and Steroid Hormone/Chromatin Interactions in Cultured Human and Murine Mammary Tumour Cells

Applicant must have strong bio-chemistry background. Experience with fractionation techniques, nucleic acid hybridization, steroid hormones, antibody production, and/or tissue culture desirable. Salary: $13,000.

Send résumé, three letters of recommendation and university record to Dr Fred R Frankel, 249 Johnson Pavilion G2, University of Pennsylvania, Phila. Pa. USA 19104.

W570(A)

Soil Scientist/ Metabolism Chemist

Jealott's Hill is the centre for pesticide research and development work carried out by the Plant Protection Division of ICI.

There is a vacancy with our Environmental Sciences Group for an enthusiastic person to lead a team studying the physicochemical behaviour and degradation of pesticides in soil and aquatic sediments. The person must have qualifications at the PhD level (or equivalent), a good knowledge of soil science and experience in studying the behaviour of chemicals in soil. An agreeable personality and an ability to work as a member of a team are also essential. The work is part of our programme for evaluating the environmental safety of pesticides.

Initial remuneration in the region of £8,500 per annum could be offered to the right person, and the Company has a Profit Sharing Scheme and a contributory Pension Scheme. Assistance with removal expenses and house purchase may also be available.

If you wish to apply, please write or telephone for an application form to:

Mr D Spence, Personnel Officer, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berkshire.

Telephone Bracknell 24701 extension 3445. Please quote reference number 79/SS/MC 3823(A)

ICI Plant Protection Division

NATURE Book Review Editor

Nature reviews a wide range of scientific books every week and several times a year also produces a major review supplement. The Book Review Editor is responsible for the selection of books, the commissioning of reviews and (in collaboration with typesetter) the preparation of all review pages for the printer. The Book Review Editor is part of the editorial team and will often call on other members of this team for advise; equally he/she will frequently be called on to advise and help these other members.

Applications (including a curriculum vitae) should be sent as soon as possible to — The Editor, Nature, Macmillan Journals Limited, 4 Little Essex Street, London WC2R 3LF.

3857(A)

DIABETES RESEARCH INSTITUTE

Biochemist or Biologist

Applications are invited for a postdoctoral research position. The research concerns electron microscopic studies on biological membranes and macromolecules. The applicant will work within the electron microscopic group.

Applications, including a curriculum vitae and names and addresses of 2 referees should be sent to *Gesellschaft zur Förderung der Erforschung der Zuckerkrankheit,* 4000 Düsseldorf 1, Auf'm Hennekamp 65. W568(A)

Australia

The University of New England

Lecturer

Department of Ecosystem Management

The Department provides Undergraduate and Postgraduate training within the Faculty of Resource Management, in the investigation and management of Biological resources. A new appointment is to be made, to contribute mainly to teaching and research in Wildlife Biology, Technology and Management. The successful applicant may be required to teach in related fields also.

Applicants should have a training in quantitative terrestrial, vertebrate ecology, preferably with a working knowledge of plant ecology, professional experience of wildlife management or of applied wildlife research, evidence of active field research and a PhD teaching experience and a knowledge of Australian fauna would be advantageous.

Salary: $16,291 — $21,401 per annum.
Closing date: 14th January, 1980
Position No.: 455

Applications, including the names and addresses of three referees and stating the position No. should be sent to the **Staff Officer, the University of New England, Armidale, New South Wales, 2351,** prior to the closing date.

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the Commonwealth Bureau of Horticulture and Plantation Crops, East Malling Research Station, Nr. Maidstone, Kent

Duties: Preparing abstracts in English for the journal *Horticultural Abstracts*, which covers world scientific literature in this field, indexing and answering scientific enquiries.

Qualifications: A degree in horticulture, agriculture, botany, or related subject, plus a reading knowledge of at least one European language (German preferred) and the ability to write good English. Applicants must be able to render the content of scientific publications into concise, accurate and readable abstracts. It is expected that the successful candidate will wish to make a career in the field of scientific literature rather than research.

Salary: In the scale £3289 to £6211, plus a compensatory allowance (taxable but not superannuable) of 3.3 per cent of basic salary to offset personal contribution to superannuation scheme. Starting salary according to qualifications and experience. Promotion to higher scales on merit.

Application forms and full particulars from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: 23 December 1979. 3818(A)

UNIVERSITY OF NATAL

DEPARTMENT OF BIOLOGICAL SCIENCES

Durban

Applications are invited from suitably qualified persons, regardless of sex, religion, race, colour or national origin for appointment to the post of:

PROFESSOR AND HEAD OF DEPARTMENT

No particular preference exists regarding the research orientation of the successful candidate. It may be botanical, zoological or specialised within either of these disciplines. Equal consideration will be given to candidates with research interests in the cellular, physiological or environmental disciplines, but the candidate must show a strong interest in the presentation of integrated biology.

Salary in the range of: R15,000 to R18,000 per annum.

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, 4001, South Africa, with whom applications, on the prescribed form, must be lodged not later than 14th January 1980, quoting reference Adv. D94/79. W564(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF ENGINEERING SCIENCE

SENIOR EXPERIMENTAL OFFICER

A vacancy exists, from 1 January 1980, for a research and development engineer to work for a period of two years on the development of an instrument to measure accurately the movements of normal and abnormal human-knee joints. The engineer will work in the Engineering Science Department in Durham, but will have the support of the Departments of Orthopaedics and Medical Physics in Newcastle. The project has the financial support of the DHSS.

Applicants should be graduates in engineering or another appropriate subject, preferably with experience of instrumentation.

For a successful applicant with two years postgraduate experience the initial salary will be in the range £4,333 to £4,910.

Applications (3 copies) naming three referees should be sent by 31 December 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham, from whom further particulars may be obtained. 3844(A)

STUDENTSHIPS

ST. JOHN'S COLLEGE CAMBRIDGE

Research Studentships

The College invites applications for a number of Research Studentships normally tenable for three years and of such value as will, in addition to the payment of fees, bring the student's total emoluments to £1,920 a year, for men who are not already members of the College but who propose to register as PhD students at the University. Candidates should have gained or have a strong prospect of gaining a first-class honours degree or equivalent.

Further details and application forms can be obtained from the Senior Tutor, St. John's College, Cambridge CB2 1TP. Completed applications must be received by April 1, 1980. 3856(F)

FELLOWSHIPS

SIDNEY SUSSEX COLLEGE, CAMBRIDGE

LINNETT-BP JUNIOR RESEARCH FELLOWSHIP IN PHYSICAL CHEMISTRY

The College Council hopes to make an election to a Junior Research Fellowship tenable from 1 October 1980 for three years. The Fellowship will be funded by British Petroleum.

Candidature will be restricted to those pursuing, or intending to pursue, research in the broad area of the chemistry and physics of solids and their surfaces.

Applicants who will be over thirty years of age on 1 October 1980 are unlikely to be elected except in special circumstances.

The pensionable emolument of a Junior Research Fellow is currently £3,555 a year, or £3,964 if the Fellow holds the degree of PhD, subject in either case to a reduction of £570 if the Fellow is normally resident in College and also to such reduction as the Council may determine on account of any emoluments received from other sources.

Further information may be obtained from the Senior Tutor, Sidney Sussex College, Cambridge, CB2 3HU.

Applications should reach the Senior Tutor not later than 18 January, 1980. 3850(E)

EMBO

European Molecular Biology Organisation

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY

SPRING 1980 AWARDS

Next deadline: February 18, 1980

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but, subject to review of progress by the selection committee, they are usually renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 18th 1980. Successful candidates will be notified of their awards immediately after the meeting of the selection committee which is on April 18th 1980.

Application forms and further details may be obtained from Dr J Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany. W563(E)

UNIVERSITY OF OXFORD

The Queen's College

JUNIOR RESEARCH FELLOWSHIP IN CHEMISTRY

The Governing Body proposes to elect to a Junior Research Fellowship in Chemistry tenable for three years from 1 October 1980.

Further particulars may be obtained from the College Secretary, The Queen's College, Oxford. 3819(E)

FRIEDRICH MIESCHER-INSTITUT, BASEL

POSTDOCTORAL FELLOWSHIP

tenable for 2-3 years at the Institute. Experience expected in protein-chemistry or biochemistry to work on purification and characterization of growth factors for mammalian cells.

Send C.V. and list of publications to Dr R R Bürk, Friedrich Miescher-Institut, P O Box 273, CH-4002 Basel, Switzerland. W578(E)

UNIVERSITY OF MÜNSTER

DEPARTMENT OF IMMUNOLOGY

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP

Candidate should have experience in biochemistry, cell biology or immunology and a research interest in the cellular basis of immune reactivity.

The position is available for 2 years at a salary ranging DM38,000 to 40,000 per annum.

Applications with c.v. and names of referees should be sent to Prof. Eckehart Kölsch, Dept. of Immunology, University of Münster, Westring 10, 4400 Münster, Germany. W567(E)

POSTDOCTORAL FELLOWSHIPS IN ASTRONOMY AND ASTROPHYSICS AT CALTECH

The California Institute of Technology invites applications for postdoctoral fellowships in astronomy and astrophysics. Awards, beginning generally in summer or autumn 1980, will normally be for one year with likely renewal for a second year. Caltech is active in observational astronomy (radio, millimeter, infrared, optical, X-ray, and cosmic ray; solar, planetary, interplanetary, stellar, interstellar, and extragalactic), laboratory astrophysics (nuclear, atomic, and chemical), and theoretical astrophysics (with emphasis on cosmology, galaxies, stars, coherent emission processes, and nuclear and relativistic astrophysics).

It is anticipated that postdoctoral fellowships (number in brackets) will be available in the following fields:

1) Solar Physics (1): H Zirin, 354-33.
2) Experimental and Theoretical Cosmic-Ray Astrophysics and Solar-Terrestrial Physics (3): E C Stone, Downs Laboratory, 220-47.
3) VLBI Radio Astronomy (1): M H Cohen, 102-24.
4) Experimental (1) and Theoretical (1) Nuclear Astrophysics: W A Fowler, Kellogg Radiation Laboratory, 106-38.
5) Theoretical Astrophysics (2): R D Blandford, 130-33.
6) Optical and Ultraviolet Astronomy (1): J B Oke, 105-24.
7) Quasar Astronomy (1): M Schmidt, 105-24.

Caltech is an Equal Opportunity Employer with an Affirmative Action Program. We encourage applications from women, members of minority groups, and persons with non-disqualifying handicaps.

Applicants should write for applications forms to the appropriate faculty member listed above at: California Institute of Technology, Pasadena, California 91125. All application material should reach the California Institute before January 15, 1980. W551(E)

ASSISTANTSHIPS

THE UNIVERSITY OF LANCASTER
DEPARTMENT OF ENVIRONMENTAL SCIENCES

Applications are invited for a Research Assistantship/Associateship in the Lunar and Planetary Unit starting on 1st January 1980 and lasting for a period of one year. The person appointed would automatically become a Co-Investigator in the Heat Capacity Mapping Mission of NASA and would work with the Principal Investigator at Lancaster on Satellite Monitoring of Sea Surface Pollution in the seas around the UK. The work would be mainly laboratory centred, involving the use of existing image processing equipment and a PET microcomputer. The principal aim of the research is to report on the feasibility of detecting oil spills in the North Sea. This aim will be achieved through the examination of new satellite images taken in the infra-red.

The appointment will be made in the salary range £3,775 to £6,355 (basic), according to qualifications and experience.

Applications (six copies) naming 3 referees, should be sent to the Establishment Officer, University House, Bailrigg, Lancaster LA1 4YW, by 7th December, 1979. Further information about the duties can be obtained from Dr G Fielder, Department of Environmental Sciences (Engineering Building).

3841(P)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BOTANY

Applications are invited for a NERC Post-Doctoral Senior Research Assistantship to investigate reproductive strategies in *Fucus* species. Candidates should have research experience in intertidal ecology and/or botany. Initial salary £4,333 per annum.

Applications, together with the names of three referees, should be received not later than 14th December 1979 by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref RV/850/N.

3813(P)

CITY OF LONDON POLYTECHNIC
DEPARTMENT OF BIOLOGICAL SCIENCES
RESEARCH ASSISTANTSHIP IN NEUROBIOLOGY (ILEA)

Applications are invited from well qualified graduates in Biology or Physiology for the above position to commence as soon as possible. The research project involves the histological and physiological analysis of the neural mechanisms underlying acoustic communication in insects. Much of the work will involve micro-electrode recording from primary and central neurons.

The appointment will be tenable for two years in the first instance and will be extended to three years on satisfactory progress. The successful candidate will be expected to register for a higher degree with the CNAA under the supervision of Dr D B Lewis.

Salary: £3,321 to £3,417 to £3,513 (includes London Weighting of £474 pa).

Please apply in writing, giving full curriculum vitae and the names and addresses of two referees, to Dr D B Lewis, Department of Biological Sciences, City of London Polytechnic, Old Castle Street, London E1 7NT. Applications should be sent within two weeks of the appearance of this advertisement. 3815(P)

CONFERENCES

STREAM ECOLOGY SYMPOSIUM
October 19-22, 1980
Augusta, Georgia USA

The Savannah River Ecology Laboratory, in cooperation with the University of Georgia's Institute of Ecology, the US Dept of Energy, and the National Environmental Research Park program, will host a symposium on the ecology of lotic ecosystems. Symposium format will include presentations by invited speakers, panel discussions, and contributed papers. Abstracts due June 1; manuscripts due August 1, 1980.

For registration and additional information contact: Thomas D. Fontaine, III, PhD, or Steven M. Bartell, PhD, Co-chairpersons, Savannah River Ecology Laboratory, PO Drawer E, Aiken, South Carolina 29801, USA. Phone: (803) 725 2472. W574(C)

SEMINARS and SYMPOSIA

Scottish Electrophysiological Society
3rd International Symposium
to be held at Edinburgh University 8-11 April 1980

Making sense of sense organs

The Symposium will present expert opinion on sensory receptors and how they work. The plenary sessions presented by invited speakers from the UK, USA, Germany, France and Holland will develop a theme from anatomy at ultrastructural and cellular levels, through the biophysics of stimulus absorption, transduction and coding to higher-order analysis and perceptual mechanisms of behaviour.

Voluntary contributions are cordially invited for the afternoon sessions and a poster session.

Please address enquiries to Dr Derek Cosens, Dept. of Zoology, West Mains Rd., Edinburgh EH9 3JT; or Professor Mike Laverack, Gatty Marine Lab., St. Andrews, Fife KY16 8LB, Scotland.

COURSES

UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY
MSc IN TOXICOLOGY

Applications are invited for a postgraduate course leading to an MSc degree in toxicology. The course, which may be attended either fulltime (extending over one year starting in October) or part-time (extending over 2 years) is organised by the Department of Biochemistry, University of Surrey, with the MRC Toxicology Unit, Carshalton; the British Industrial Biological Research Association, Carshalton and Shell Toxicology (Tunstall) Laboratory, Sittingbourne. During the course instruction is given in these collaborative laboratories as well as at other major toxicological institutions. A limited number of MRC studentships are available and for suitable students these may be extended for continuation to study for a PhD.

The Medical Research Council, the Royal Society and the Royal College of Pathology have identified toxicology as a priority area for research training and therefore support the encouragement of first class students from a variety of disciplines to become involved in the science of toxicology. In modern society contact with potentially toxic chemicals is increasing. Problems may arise from the use of drugs for medical purposes, from occupational exposure to industrial products or intermedites and from environmental exposure to natural or synthetic substances.

The course, which was the first of its kind in Europe, is designed to provide graduates in science, and medical and veterinary graduates, with an understanding and appreciation of the many disciplines involved in toxicology. Particular emphasis is placed on aspects related to the biochemical mechanisms of chemically-induced toxicity, and the assessment of toxicological hazard in the manufacture, use and disposal of new chemical compounds, pesticides and medicines. The course provides a broad biological education and is a suitable introduction for those intending to undertake research on the interaction of chemicals with biological systems.

There are numerous interesting opportunities for scientists, educated initially in different disciplines, who have acquired additional knowledge of toxicology. These may be in industry, government regulatory bodies, or research institutes with good career prospects in both laboratory work and administration.

Further information and application forms to be returned by February 16th can be obtained from:
Dr R S Jones, Department of Biochemistry, University of Surrey, Guildford, Surrey, GU2 5XH. 3851(D)

Catalogue of the Universe

PAUL MURDIN, DAVID ALLEN and DAVID MALIN

Some of the finest photographs that have ever been taken of over 300 astronomical bodies are reproduced in this book and complemented with an interesting and readable text written by professional astronomers.

'This is a book with superb pictures taken with the best available equipment, making up a glorious display of the most spectacular objects in the Universe known to us to-day. I know that it will interest everybody — professional astronomer or beginner.' *Patrick Moore*

276 x 219 mm 288 pp. 53 colour subjects, 300 half-tones and line subjects

Spherical Models

MAGNUS J. WENNINGER

This beautifully illustrated and charming book from the author of the widely praised *Polyhedron Models* explains how to make models of spherical polyhedra from simple materials, using simple mathematics, a ruler and a compass. The author gives detailed instructions and illustrates these with photographs, drawings and computer graphics. This book will be enjoyed by all those interested in recreational mathematics and by students and teachers of art, design, architecture and mathematics.

253 x 184 mm 160 pp. numerous illustrations, one plate

Practical Astronomy with your Calculator

PETER DUFFETT-SMITH

Written in a clear and lively style and uncluttered by the theory behind the calculations, this book will have a wide appeal to amateur astronomers of all ages, as well as serving as a useful reference source for professional astronomers. It gives simple step-by-step instructions for the prediction of future astronomical events such as planetary phases and eclipses of the Sun and Moon. All that is required is a modest scientific calculator.

198 x 129 mm 140 pp. 45 tables, 26 line diagrams

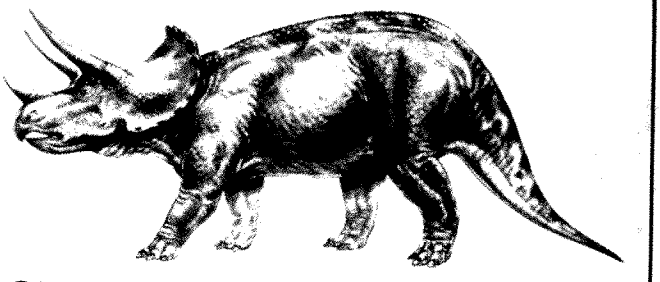
The Messier Album

JOHN H. MALLAS and EVERED KREIMER
Edited by OWEN GINGERICH

Based on the authors' highly praised series of articles in *Sky and Telescope* this volume is a blend of expert astronomical observations, superb pictures and historical lore that will be welcomed by amateur and professional astronomers and beginning observers. The book recalls the life and works of Charles Messier and other eighteenth-century astronomers, and illustrates the most spectacular sights in his list with a 31-page gallery of superb colour photographs.

'It is a handsome volume, well produced, and good to dip into . . . .' David Allen in *Sky and Telescope*

228 x 152 mm 248 pp. 31 colour subjects, 100 line diagrams
0 521 23015 2 **£6.95 net**



What Little I Remember

OTTO FRISCH

In this delightful autobiography the late Otto Frisch relates some of the most exciting developments of modern physics, including his discovery of nuclear fission, a term he himself coined. Professor Frisch describes vividly how he witnessed the unravelling of the double helix, the making of the first atomic bomb and the birth of radioastronomy. His entertaining anecdotes of the many great scientists he met during his lifetime create the background for his pen portraits and the many photographs included in the text.

'This is a happy book, from which the author's personality and his enjoyment of physics, of music, of life emerges clearly.' Rudolf Peierls in *Nature*

216 x 138 mm 240 pp. 47 half-tones, 6 line figures
0 521 22297 4 **£9.50 net**

Dinosaurs and their Living Relatives

BRITISH MUSEUM (Natural History)

This book is being produced to coincide with a major new permanent exhibition at the British Museum (Natural History). The exhibition explores the relationships between dinosaurs (animals that died out 65 million years ago) and other animals, both living and extinct, notably birds and crocodiles. Most of the material in the exhibition is being specially adapted for the book, and the lively and informal approach is retained throughout. The book is extensively illustrated with beautiful colour pictures, and there is a useful glossary as well as notes on the lifestyles of many of the dinosaurs.

216 x 216 mm c. 72 pp. numerous illustrations
0 521 22887 5 **Hard covers £9.00 net**
0 521 29698 6 **Paperback £2.95 net**

Published jointly with the British Museum (Natural History)

Pick a Six-Pack.

The quick, easy approach to protein purification... Miles Hydrophobic Chromatography six-packs.

Test and choose. That's all it takes to establish the correct gel for your purification problem when you use our six-column Shaltiel[1-3] hydrophobic chromatography kits packed with a range of top-quality gels.

Systematic separation.

Kit I: an agarose-C_n series of six small plastic columns containing 1.0 ml each of six alkyl agaroses, and Kit II: an agarose C_n-NH_2 series of six columns containing 1.0 ml each of six ω-amino alkyl agaroses, may be used serially to determine the most appropriate purification medium for a given protein.

Optimum resolution.

Columns *discriminate* through hydrophobic and ionic interaction... *purify* through *selective retention* and *exclusion*.[4] Further resolution can be achieved during elution.[5]

Maximum convenience.

Time- and cost-efficient...depending on the protein, as much as 10 mg can be bound per ml of gel...agaroses can be used repeatedly after appropriate washing between uses.

Multiple options.

Agaroses in both kits are also available individually as 50% gel suspensions. They include: ethyl agarose, butyl agarose, hexyl agarose, octyl agarose, decyl agarose, ω-amino ethyl agarose, ω-amino butyl agarose, ω-amino hexyl agarose, ω-amino octyl agarose, ω-amino decyl agarose.

Save time and money with hydrophobic chromatography techniques...pick the Miles six-packs.

CHRISTMAS BOOKS

When in London do as the Romans did-settle on the Barbican. (It's the perfect place for a conference.)

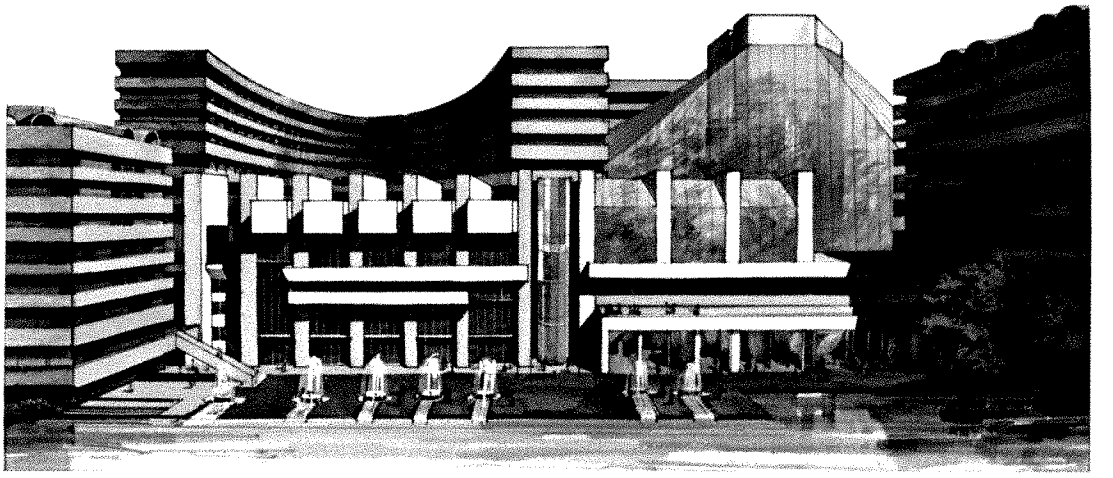
It's a long time since the Romans left. (About 1,500 years, in fact.) But you can still see traces of their occupation–including remains of the original Roman city wall.

The Barbican Centre is located in the heart of the City of London. So it's surrounded by centuries of history and culture plus the bustle and excitement of one of the world's leading financial communities.

The Barbican Centre itself, however, will be among the most modern and well equipped conference centres available.

There's a spacious conference hall. A variety of lecture theatres, seminar and committee rooms. A Film Theatre–with the most advanced audio-visual equipment. The Barbican Theatre. Interpretation facilities for six languages. A display and exhibition area. Plus a plentiful supply of bars and restaurants.

The Barbican caters for cultural appetites, too. The Royal Shakespeare Company will have its permanent home there. So will the London Symphony Orchestra. And the Guildhall School of Music and Drama. There's an Art Gallery. A Sculpture Court.



In other words, it's as civilised a forum for a conference as even the Romans could have dreamed of.

We're already taking bookings from 1981 onwards.

So, if there's anything more you'd like to know about the Barbican, just contact our Conference Sales Director.

And don't worry. She speaks English. Not Latin.

Barbican Centre 11 Cromwell Tower, Barbican, London EC2Y 8DD, England. Telephone: 01-638 4141.

A display and exhibition area with a total of 64,000 square feet (5,500 square metres).

The Barbican Conference Hall comfortably seats 2,000 delegates.

A variety of lecture theatres, seminar and committee rooms to take anything from 5 to 265 people.

The Film Theatre seats 275 people.

The Barbican Theatre seats 1,150.

MIX AND SPIN PERCOLL™

DENSITY MARKER BEADS NOW AVAILABLE for calibration of gradients of Percoll

Now centrifugation is simpler, quicker and gives much greater resolution than you ever thought was possible.

- Self-generating gradients in 30 minutes or less
- Isoosmotic throughout the gradient
- Non-toxic to cells and viruses
- Does not interfere with enzyme assays or quench radioactivity
- Low viscosity for rapid isopycnic or rate zonal separations
- Suitable for cells, viruses and subcellular particles

Pharmacia Fine Chemicals

Circle No. 04 on Reader Enquiry Card

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Using Iodine-125?

New Microvial*

- reduced exposure
- reduced contamination risk

Reduced exposure

The new packaging consists of 2 parts

- An outer plastic container incorporating a steel shield
- An inner plastic vial with a conical glass insert containing the iodide solution

Reduced contamination risk

The cap of the plastic outer container is keyed so that it can be used to unscrew the cap of the inner vial — no need to handle this vial from start to finish.

At Last! A Reliable Incubator Under $100

Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and FASEB Meetings

With this Modular Incubator Chamber you no longer have to worry about the inherent variability (due to CO_2, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators.

Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv resistant polycarbonate.

Multi-purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only $95.* To order or for further information phone or write Billups-Rothenberg, Inc., Dept. N.T., P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

INDEXES

Annual Indexes are available for the years 1971-1978. The year's papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

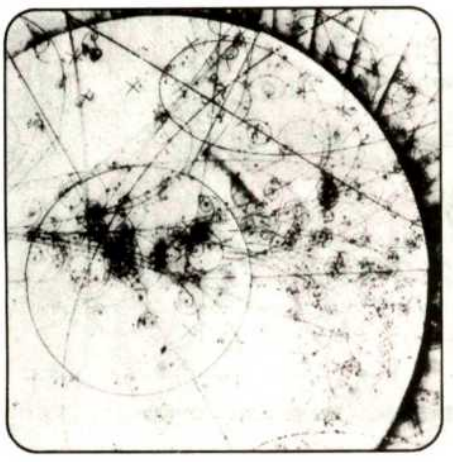
Cutting laser technology down to size

The world's first diode laser optical recording system, developed by Philips, is remarkable, not only for what it can do, but also for how it does it.

For in order to record and/or retrieve 10^{10} bits of information on a pre-grooved, double-sided, 12-inch disk, a breakthrough in state-of-the-art optical recording technology was required. Which is precisely what we achieved.

The optical read/write head shown here is a miracle of micro-precision engineering. Employing an AlGaAs (Aluminium Gallium Arsenide) diode laser and associated semiconductor modulator, it produces sufficient pulsed light output to write, or 'burn', 1-μm data pits into the disk's tellurium-based recording film. A 40-gram optical system, as well as electro-optics for tracking and focusing are also

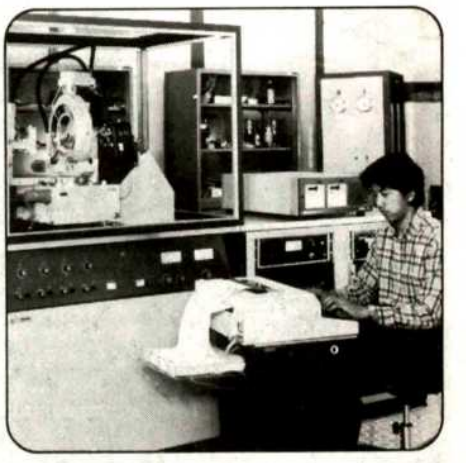


PHILIPS

contained within the ultra-compact head.

Light output from the laser is split by the optical system into two beams: 90 percent intensity for recording and 10 percent for reading. The read beam passes two mirrors and a beam splitter that are arranged to recombine the record and read beams at the objective, which focuses onto the information layer in the disk with an accuracy of 1-μm.

And to complement the precision and compactness of the optical read/write head, equally ingenious radial tracking and error-detection correction systems had to be developed.



Diode laser optical recording is one example of Philips' ability to translate advanced technology into practical innovation. Here are some others.

CERN, the Geneva-based European Organisation for Nuclear Research, is to install four 500kW, 200MHz power amplifiers for their Super Proton Synchrotron, which is currently operating at a level of 400GeV. The new power amplifiers will provide additional RF power to double the Synchrotron's present capacity to facilitate experiments in high energy physics. Each of the four amplifiers employs 17 air-cooled coaxial power tetrode tubes of metal ceramic construction; power output per tube being approximately 37.5kW.
The contract, awarded to Philips, calls for the supply and installation of the amplifiers as well as supply of spare tubes for a period of ten years.

Fibre optics transmission. Trials on a long haul fibre optics telephone transmission route, covering a distance of ninety-six kilometres, has been successfully completed at the Philips laboratories in the Netherlands. Essentially, the route comprises a 19mm diameter cable containing six 0.1mm fibres with a regeneration stage every eight kilometres.

Tokyo Institute of Technology has installed a Philips PW1100 computer-controlled Single-Crystal Diffractometer to assist in structure analysis of inorganic materials. One of Japan's leading universities, the Tokyo Institute of Technology, is noted for its academic research into the field of inorganic materials. And the new installation will be used by crystallographers from all over the country.

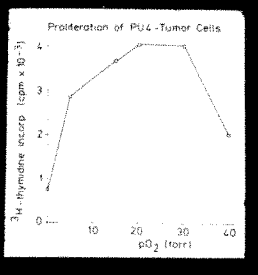
Philips working on advanced technology

A new approach in tissue culture

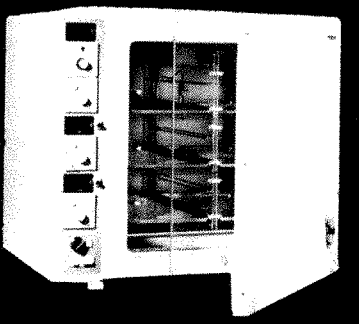


PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents



PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

*In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

Public interest representation on research councils?

Who runs Britain's science? A simple question capable of an exceedingly complex answer, so widely is science dispersed across the scene. But for university scientists and many others in specialist laboratories there is a relatively simple answer: the research councils, which fund individual research projects, provide studentships and fellowships and operate a large number of major laboratories, many with an international reputation.

And who sits on the research councils and on the Advisory Board for the Research Councils, which coordinates their efforts and provides advice to the Secretary of State for Education and Science on how to spend £300 million annually? Distinguished scientists and medical men, a handful of industrial scientists and one or two farmers (on the Agricultural Research Council). Council members are appointed by the Secretary of State.

Now to the best of our knowledge members of the research councils fulfil their duties diligently, giving up time that they can often ill afford to attend meetings, understand complex issues and help to steer policy. We do not question the effort that they put in. What should be questioned is whether the composition of the councils is right for the 1980s, and whether there should not be a greater representation of what, for want of better words, may be called the public interest.

Before we are accused of mischievously allowing amateurs and meddlers to interfere with such delicate issues as who gets grants, it should be made clear that each research council has a complex structure of committees which handles such matters; council only concerns itself with broader issues. But these could profit by being understood and debated by people with an interest in science but who have not necessarily followed the research path.

There is no shortage of constituencies which could make valuable contributions. They could include trade-unionists, teachers, those in overseas development, politicians, science writers, lawyers, businessmen, bankers and doubtless many others. Since much of science is international, there should be no compelling reason why a foreigner (particularly from the EEC) could not be incorported for some purposes — one or two other countries already do use foreign help in deciding science policy.

Of course scientists themselves would have to be protected against being swamped by non-scientists, but the model of the Genetic Manipulation Advisory Group, which satisfactorily incorporates several 'public interest' members, would bear study. One of the weaknesses of Britain is the lack of cross-communication between experts in different disciplines. Here is a chance for an experiment in trying to build up such cross links. □

Flying university in trouble

HIGHER education and scholarship in Poland recently acquired an unusual and innovative institution — the Society for Academic Courses, better known by its nickname of the 'Flying University'. This society arranges lectures, seminars and discussions to satisfy the needs particularly of young students given to questioning the information obtainable through conventional channels. Although a large fraction of the courses currently on offer concerns contemporary history and the social sciences, scientists are amongst the sponsors of the society, and a course is included on moral issues in biology. The society has received notable public support from physicist Janusz Groszkowski, former chairman of the Polish Academy of Sciences, who resigned his official posts in 1976 in protest against police interference in academic life.

The educational experiment has not gone entirely smoothly. The police had been regular visitors to houses where seminars are held, and several lecturers have been detained and fined on various charges of disturbing the peace. Seminars have also been visited frequently by gangs of students intent on doing damage. This term only the inaugural session, by the sociologist Witold Bartoszewski and the physiologist Jan Kielanowski (a member of the official Polish Academy of Sciences) was given before the wreckers moved in. Two of those involved, Dr Bartuszewski, and Piotr Naimski, a biochemist, have each been fined 5000 zloty — the equivalent of an average month's academic salary — for their activities.

An international support committee has just been formed to provide encouragement for an independent intellectual life in Poland by the provision of material help, including books, and by the publication of research results. It is a cause that scientists who have a large amount of freedom to say and do what they wish may wish to contribute to.

The address is 11 Bevington Road, Oxford. □

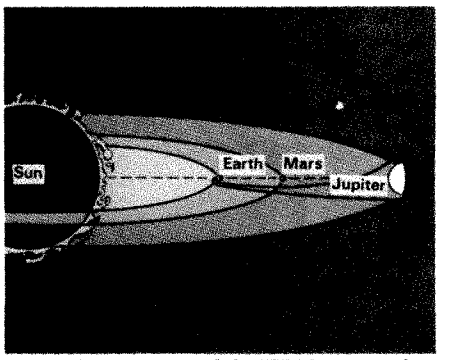
NASA told to delay space mission with European scientists

A US congressional committee last week directed the National Aeronautics and Space Administration to impose a two-year delay on a joint solar research project with European scientists, the International Solar Polar Mission.

The House Appropriations Subcommittee responsible for NASA's budget said the delay was necessary because of difficulties faced in the development of the space shuttle, from which two spacecraft would be launched simultaneously to orbit the sun in opposite directions.

In addition, the subcommittee has told NASA that both the solar polar mission and the planned Project Galileo mission to Jupiter, which the agency has already suggested postponing from 1982 to 1984, should use modified Centaur rockets for the launch from the shuttle, rather than the 'inertial upper stage' (IUS) currently under development by the US Air Force.



The instructions were contained in a letter to Dr Robert Frosch, administrator of NASA, from Appropriations Subcommittee chairman Mr Edward Boland. Two years ago Mr Boland tried to persuade the House of Representatives that Project Galileo should be killed entirely, and was only defeated after intensive lobbying by the space science community.

The legal status of the directive is unclear, since any change of plan would need to be endorsed by at least three other congressional committees. But with the space shuttle running into increasing delays and rising costs, space science projects have become vulnerable prey to budget-cutting politicians.

The solar-polar mission is a joint effort between NASA and the European Space Agency. The two spacecraft are currently scheduled to be launched in February 1983, and after a fly past Jupiter to enter polar orbits around the Sun in 1987.

Problems have arisen because delays in the shuttle development programme — now over a year behind schedule — have contributed to difficulties in guaranteeing that the IUS could be developed sufficiently fast to provide the thrust needed to launch the two spacecraft from the shuttle by the planned date.

Similar problems have affected the Galileo project, which is also planned by NASA to use the IUS, and for which NASA has now decided that there should be separate launches for the probe and the orbiter in 1984. Previously it had been planned that both vehicles would be launched simultaneously by the IUS, but this could only have been done with a 1982 launch making use of the extra pull from the planet Mars.

Planned trajectories of the ISPM spacecraft: a 2-year delay will add greater strain to ESA's badly stretched space science budget.

Last summer NASA had rejected the Centaur as an alternative to the IUS, largely because of the extra development costs, which it calculated would have added an extra $100 million to the cost of Galileo, whose predicted budget has already risen from $450 million to $675 million because of the time delay.

In his letter to Mr Frosch, however, Mr Boland says that his subcommittee will only let Galileo proceed "if NASA develops a Centaur upper stage designed to fly a combined orbiter-probe Galileo mission in 1984", and that the solar-polar mission, also using the Centaur, must be put back to 1985.

ESA officials point out that, under their agreement with NASA, the US agency would have to bear any additional launch costs for the solar-polar mission. However they are seriously worried about the effects of a two-year delay, not only because of the extra costs of keeping scientific and technical teams together, but because it could initially mean the underutilisation of a small space science budget, as well as upsetting medium-term budget priorities.

NASA received more bad news last week, when the Office of Management and Budget rejected several proposals for new programme starts which the agency had submitted for possible inclusion in the President's budget request to Congress for the fiscal year 1981. The only new start to have received OMB's blessing is said to be the proposed launching of a gamma ray observatory. However the budget office has not supported NASA's request to start development work on a propulsion system necessary if a joint mission is to be carried out for encounters with Halley's Comet and the Comet Tempel 2 in 1985.

NASA officials are now hoping that the White House can be persauded to support some of the projects deleted by OMB. In particular discussions are taking place over joint sponsorship between the Department of Defense, the Commerce Department, and NASA about establishing a national oceanic satellite system, a successor to the ill-fated SEASAT. □

UN split over science policy machinery

Member countries of the United Nations remain sharply divided over the type of internal machinery that the UN should set up to help implement decisions reached by the Conference on Science and Technology for Development (UNCSTD) held in Vienna in August.

At stake is the future of the Office of Science and Technology, currently the prime focus for science policy activities within the UN, but which many developing countries consider inappropriate, in its present form, to an expanded role.

Delegates attending the second committee of the UN General Assembly in New York last week, which is examining the conclusions of the conference, voiced unanimous approval for its decision to establish a new Intergovernmental Committee for Science and Technology for Development (IGC) open to all member states of the UN.

As in Vienna, however, opinion is divided over the nature of the secretariat which will service this committee. Many developed countries, and in particular the nine member countries of the European Economic Community, expressed their opposition to any new institutional machinery. They argue that the IGC could be adequately serviced by a strengthened department of International Economic and Social Affairs, under which OST now operates.

The Group of 77 however, which has been negotiating for the developing countries, has called for the abolition of the OST, and for its function and resources to be transferred to a new, independent secretariat, headed by an under-secretary general directly responsible to the Director-General for Development and International Economic Cooperation, Mr Kenneth Dadzie.

Mr Dadzie has himself offered a compromise solution which would create a new secretariat, but keep some resources within the Department of International Economic and Social Affairs. However many delegates feel that a clear division of responsibilities is necessary, and Mr Frank Da Costa, Secretary-General for the UNCSTD conference, has argued strongly that the Group of 77's proposal should be accepted.

After two days of open session, the second committee adjourned for informal discussions on the alternative proposals. A final decision is expected next week.

In addition to servicing the IGC, the new secretariat would be responsible both for co-ordinating science and technology activities within the UN system, and for providing support to the group of experts which the IGC will set up to study plans for a new financing system for science and technology for development. □

Recombinant DNA experiments to remain under safety guidelines

There will be no major removal of experiments using recombinant DNA techniques from safety guidelines laid down by the National Institutes of Health, writes **David Dickson**

Last week the director of NIH, Dr Donald Fredrickson, proposed in response to a recommendation from the Institute's Recombinant DNA Advisory Committee (RAC) that physical containment levels for virtually all experiments using the disabled K-12 strain of the bacterium *Escherichia Coli* should be reduced to the P1 level.

However he rejected the committee's suggestion that the experiments be formally exempted from the guidelines — and hence from NIH enforcement — proposing instead that they be placed in a special class which would still ensure that the containment requirements were met.

Dr Fredrickson's proposals were announced in the *Federal Register* last Friday (30 November) and follow a close scrutiny of the reasoning which led to the RAC's decision, taken by a vote of ten to four, with one abstention, at the committee's September meeting.

Rather than giving precise reasons for his decision, Dr Fredrickson lists the various events necessary for a serious accident to occur. In each case he quotes the opinion of scientists that the chance of such an occurrence is relatively low; and he points out that when a series of small probabilities are multipled together, the chance of a sequence of events is "exceedingly low".

On the question of whether *E coli* could cause an epidemic by passing from one person to another, for example, he quotes the conclusion of Dr Eugene Gangarosa, writing in a recent issue of the *Journal of Infectious Disease* that an epidemic "does not seem remotely possible".

Similarly in response to the question of whether *E coli* K-12 is pathogenic, Dr Fredrickson quotes Dr Sherwood Gorbach's conclusion that the disabled bacterium is intrinsically impaired in most, if not all, of a variety of virulence factors, all of which are required by a micro-organism to produce disease.

Taken together, suggests Dr Fredrickson, this evidence is sufficient to reduce containment levels for the bacterium to P1. However he says that he is not proposing to exempt the experiments, since the term 'exempt experiment' as currently used in the guidelines "should only be used for experiments for which no containment level is specified and for which no registration with the IBC is required".

As an alternative, Dr Fredrickson has proposed creating a special class within the guidelines for experiments using *E coli* K-12, except for otherwise exempt or prohibited experiments, or as otherwise specified. Experiments in this class would require P1 containment including a ban on mouth pipetting and the requirement that all biological wastes are decontaminated.

"For these experiments no memorandum of understanding and agreement . . . need be submitted, nor is any registration with NIH necessary."However, suggests Dr Fredrickson, for these experiments, prior to their initiation, investigators must submit to their institutional biosafety committee a registration document that contains a description of:

- the source(s) of DNA,
- the nature of the inserted DNA sequences, and
- the hosts and vectors to be used.

The IBC will review all such proposals submitted by investigators, although such review will not be required prior to initiation of experiments. An exception, however, requiring both prior review and approval by the IBC is any experiment in which there is a deliberate attempt to have the *E coli* K-12 efficiently express any gene coding for a eukaryotic protein.

Elsewhere in this proposed revision to the guidelines, Dr Fredrickson repeats his proposal to introduce a new section covering in detail the way in which private companies can register their experiments with the NIH and submit them where necessary for approval to the RAC, but on a voluntary basis.

Dr Fredrickson says that a number of objections to this process have been received by NIH, claiming a voluntary system of regulation to be inadequate. However he also points out that the RAC voted by 11 to none, with four abstentions, in favour of these proposals, and says that he is therefore intending to include them in the revised guidelines. □

US legislators reject moratorium on nuclear power

In its first significant vote on nuclear power since the Three Mile Island accident last March, the US House of Representatives last week rejected by 254 votes to 135 a proposal that the Nuclear Regulatory Commission be required to impose a six-month moratorium on issuing construction permits for new nuclear power plants.

In a similar vote last July, the Senate had also rejected a moratorium proposed by Senator Edward Kennedy by 57 votes to 35. Since then, however, a national poll has shown 57% of those interviewed to favour such a move — and supporters of the moratorium were therefore disappointed not to have done better in the House vote, where they had hoped to pick up considerably more supporters.

The moratorium proposals have been the major focus of public debate since the TMI accident, much of it symbolic since the NRC has itself announced that it will not grant any new permits until it has absorbed the conclusions of the President's Commission of Inquiry, chaired by Dr John Kemeny.

In presenting the Commission's report last month, Dr Kemeny said that eight out of the 12 members of the Commission had favoured a moratorium of some kind; but no more than six — less than the needed majority — could agree on specific conditions under which a moratorium would be terminated.

Last week's proposal was put to the House by Representative Edward Markey, a Democrat from a working-class district of Boston, who argued that it was not meant to be a pro-nuclear or an anti-nuclear statement, but merely to signify that nuclear power should be made safe.

The TMI accident demonstrated that the regulatory framework had failed, and fundamental reforms were needed to make nuclear power safe. The amendment "would send a message loudly and clearly to the industry and the Nuclear Regulatory Commission that Congress will no longer tolerate any future corner-cutting in the area of nuclear safety", Mr Markey said.

Opponents of the moratorium, however, argued that it was unlikely to have any significant effect — and that recent events in Iran had underlined the need for nuclear power to reduce dependence on foreign oil.

"The passage of the Markey amendment would be used by certain sectors of the media to dramatically harm public confidence in nuclear energy all across the world in the same way that they use the TMI accident to sensationalise and exaggerate nuclear hazards", said Mr Mike McCormack, chairman of the House Science Committee's Energy Subcommittee.

After the amendment had been defeated, Mr Markey said he still felt it was a good beginning "considering the 25 years of lobbying for nuclear energy and the very intensive effort by the utilities and the reactor manufacturers during the past few weeks".

In contrast Mr Carl Walske, President of the Atomic Industry Forum, said: "We think the House sent a very good message to the Ayatollah in voting it down". □

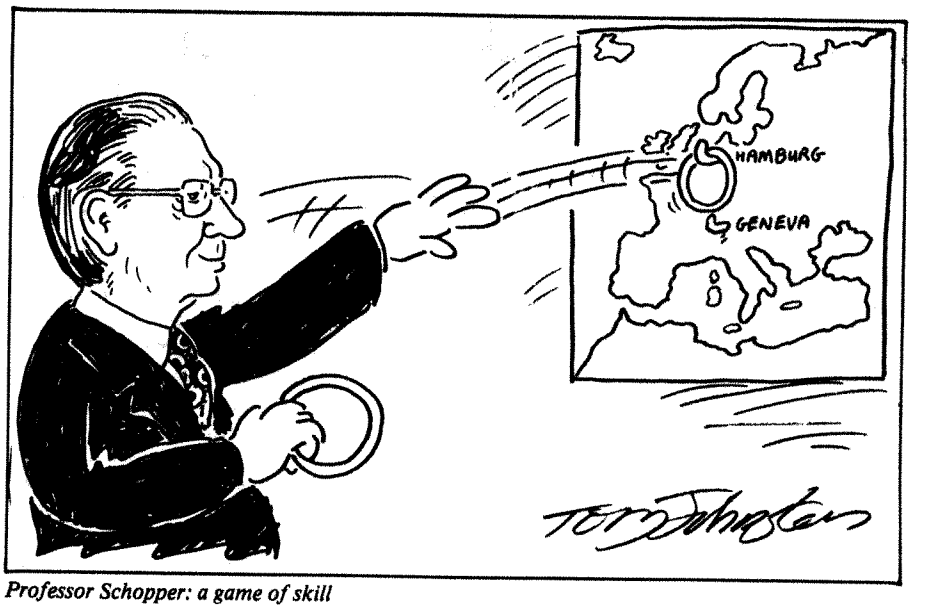
West Germany to propose big new accelerator

TODAY physicists at the Deutsches Elecktronen-Synchrotron (DESY) hope to hear that they may go ahead with a proposal for a new two-stage, DM 700 million electron and proton collider to be built under a park near DESY in Hamburg.

The accelerator would be called HERA for 'Hadron Electron Ring Accelerator', and would provide collisions between 35 GeV electrons and 400 GeV protons. This would create the deepest probe yet of the three quarks which bind together to form the proton, and would take physicists one step forward to discovering whether the quark itself has structure.

If the West German ministry for research and technology (BMFT) and Hamburg City Council grant DESY leave to propose, HERA may be before the minister by January. Bjorn Wiik, who was behind a similar (but rejected) proposal at the European nuclear centre, CERN, has already progressed a long way with the design of HERA.

Furthermore, the BMFT is believed likely to turn a sympathetic ear to the project: the ministry is said to have a surplus of some DM 300 million of research money, and the Minister, Dr Volker Hauff, has frequently said that he wants to secure the future for DESY.



HERA is a project in two parts. The first is the building of a tunnel, deep in sand and the construction of an electron ring. "Surprisingly it is not easier to build a tunnel through sand than through rock" said a DESY spokesman. The tunnel would need concrete walls, magnifying the cost.

The cost of HERA, part one, would be DM 300-400 million. Part two involves the construction of a superconducting proton ring to accelerate protons to some 400 GeV; this would cost an equal amount.

It thus appears that the likely beginning of HERA will be a single electron ring of 35 GeV. This alone is of little use. But an electron ring one way round is a positron ring the other. So HERA will start by colliding electrons with positrons (their antiparticles) at a total energy of 70 GeV.

DESY insist that it would complement rather than compete with the large electron positron ring (LEP) that CERN hopes to build.

CERN's LEP would be designed with conventional magnets to reach an energy high enough to produce the Z^0, a particle predicted by the Weinberg-Salam unification of the weak and electromagnetic interactions. (The predicted mass of the Z^0 is around 90 GeV.) With superconducting magnets (and accelerator cavities, an unproven and complex technology) LEP would reach up to the 150 GeV or so needed to produce pairs of W^+ and W^- — the other prominent particles predicted by Weinberg-Salam.

Professor Schopper: a game of skill

HERA, on the other hand, without superconducting bending magnets or cavities, would not reach the Z^0. Its role would be to look at the 'interference' between the photon and the Z^0 in electrons — positron interactions. (When they interact through electromagnetism, electrons and positrons exchange photons; through the weak interaction, almost completely masked at low energy by electromagnetic effects, they exchange Z^0s). At HERA energies, the interference would be a maximum.

Superconducting magnets and cavities are not part of the plan for HERA's electron ring, says DESY; but if they do become available it would no doubt be tempting to DESY to raise HERA towards the Z^0. A team at Karlsruhe have already had some success in superconducting cavity design.

Nevertheless the true goal of HERA is e^--p collisons, not e^-e^+. "We don't want to take the Z^0 and the Ws from CERN" said the spokesman. "There is no war."

If HERA goes ahead, it would be likely to find international support, as have the present DESY electron rings DORIS and PETRA. The director of DESY, Professor Herwig Schopper, refused access to PETRA to groups composed purely of one nationality — including German. Thus researchers at DESY now include more non-German physicists than German. The French and British have the strongest representations at DESY; Japan, China and the US are also there. Italy, for the moment, is absent.

Schopper, however, may not remain director of DESY beyond the end of his term on 31 December 1980. On 1 January 1981, CERN itself needs a new Director-General, and Schopper is considered by many to be high on the list. CERN Council meets in two weeks — on 19 December — and the state of CERN-DESY relations at that moment may be assumed to be an important factor. DESY always raises the fear at CERN of competition for LEP, and the surreptitious announcement of HERA — within a closed meeting of the European Committee for Future Accelerators — has done little to dampen it. **Robert Walgate**

PETRA apprehensive of US rival

As PEP, the US rival to West Germany's PETRA electron-positron collider, approaches commissioning in the new year, PETRA physicists are concerned that PEP's likely higher event rate will eclipse the German machine.

PETRA has faced problems of resonances in the machine as it accelerates from its injection energy up to the experimental region. PEP will take injection at the experimental energy, and so avoids most of the resonances.

PETRA experiments have each collected "a few hundred" events in a year's operation. They have included evidence for the 'gluon' (the photon of the quark-quark force), and excited states of the upsilon (which contains a beauty quark and its antiparticle), but 'truth' (the quark beyond and pairing with beauty) remains to be found, as does Z^0-photon interference (which needs a 4-5 times higher event rate) and the details (*à la* charm) of the beauty spectrum.

In January, there are plans to boost PETRA to 36 GeV (total energy) by increasing the number of accelerating cavities from 32 to 60, but that will introduce yet more resonances. "If they get a factor five more events" said one DESY physicist this week, refering to PEP, "then we will be overtaken". This cloudy future may be one element encouraging DESY to make a strong play for HERA. □

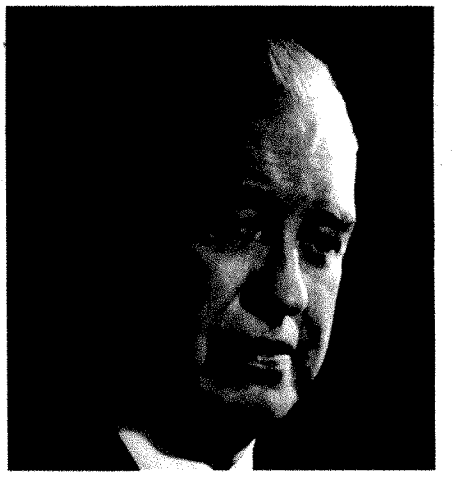
Universities should opt for teaching or research



In his anniversary address to the Royal Society last week, Lord Todd, the Society's President, lamented the deteriorating health of Britain's science and argued for a restructuring of the university system. Here we publish extracts from his speech.

THE rapid growth of the university system in the 1960s brought about a vast expansion in tenured staff usually by the recruitment of relatively young men and women taken from the normal supply of university graduates and not invariably of the highest quality. Many, if not most, of these remain today at the same institutions and are likely to do so for perhaps another two decades under the tenure system.

A detailed study of chemistry departments in British universities has been made by Professor Colin Eaborn who summarised his findings thus: "At present only 7.8% of the staff of chemistry departments are below 35 years of age; the proportion will probably fall to about 4% in five years' time and rise to only about 9% in ten years time. The proportion below 40 years of age, now 26% will fall to about 12.5% in five years and to about 10% in ten years time. During those ten years the proportion of staff over 50 will rise from the present 28% to about 62%."

Viewing Europe as a whole, the European Science Foundation suggests that the chance for a junior research assistant to reach a permanent university appointment has gone down from about 70% during the 1960s to about 15% in this decade. The outlook is indeed bleak. Surprising though it may seem, the academic research profession has within a few years been transformed from one of the most mobile to one of the most static. This is particularly so in the United Kingdom, where the economic stagnation of recent years has all but staunched the flow of academics in mid-career into other occupations. Many young scientists are seeking to retain their present precarious positions by hand-to-mouth grants because they fear that a change to another university or research institute might jeopardize their chance of obtaining a permanent appointment.

Several awkward, even painful, questions arise. Is it, for example, to continue to be taken as an article of faith that all established academics are capable of first-class research and that all students obtaining first-or upper-second-class honours degrees should be encouraged and provided with the wherewithal to pursue academic research? The answer to both questions must, I fear, be no. If we continue to believe that each department in every one of our present universities should have a substantial research school the strain on our financial resources may become intolerable.

Lord Todd: revise the dual support system

The dual support system of the University Grants Committee and the Research Councils would ideally ensure that extra funds for the support of research were concentrated on those most likely to spend them well; as things now stand, however, while there is no reason to believe that really able young scientists with good projects to put forward will be denied temporary funding to initiate them, the prospects of their being given a sufficient measure of permanence to build up a centre of excellence in their institution is small.

It is not possible — and it may not even be desirable — that all departments of, say, chemistry or physiology should stand out for the high quality of their research. Some, for example, have too small a staff adequately to sustain undergraduate teaching and to supervise at the same time programmes of post-graduate work which all departments in all disciplines appear to regard as the essential breath of life. Need this requirement for large postgraduate programmes be universal?

It is a remarkable fact that in proportion to population there are more institutions awarding PhDs in physics in the UK than in the US. In the US we find many more institutions devoted to professional education and applied sciences and there are many distinguished universities whose reputation rests substantially on the quality of their basic teaching. Such diversity in our institutions should be encouraged. Why should there not be some differentiation between those who teach and those who pursue research?

Unfortunately the present machinery for the support of higher education and research in the United Kingdom was not devised for the encouragement of diversity. For all its undoubted virtues the University Grants Committee system does require that universities should compete within what is increasingly a common framework of objectives. So competition between them is almost always on familiar terms.

Preliminary (and anecdotal) evidence suggests that in this competition Oxbridge and the older civic universities are winning out. If this be the case and the trend continues then we will end up with a hierarchy in which the universities lower in the pecking order will be trying to do the same things as the others but doing them with students who are not suited to them and would do better and become more useful citizens with a more vocational type of education.

If we are to change our present university pattern, the mechanisms by which we support research in academic institutions may also have to undergo some changes. Project grant applications will no longer be assessed simply on their merits alone without reference to the circumstances under which the research is to be carried out. Research projects in a given field will tend to be concentrated in one, or in only a very few, centres with considerably larger research groups than are usual today. It may well become necessary for the research councils to be more selective in the way in which postgraduate studentships are allocated to university departments; more radically, they may even have to think of making the grants to students of exceptional promise rather than to their potential supervisors. Another convention that may have to go is that every reasonably able PhD graduate can expect as of right to have two or three years of postdoctoral research during which he can establish a claim on a tenured research post.

The frequent frustration of this expectation is one of the saddest of the current symptoms of malaise in our university research. But the vigour of our research enterprise would surely suffer if all those concerned were now provided with a formal tenured career structure as many of them are now asking despite the current staff structure in our universities.

Unfortunately there is no quick or easy answer. A reduction in the university retiring age to 60 without any reduction in pension would undoubtedly speed up return to a normal age distribution, but would be expensive. Encouragement of voluntary retirement at 55 with generous financial compensation has also been suggested but would probably not be welcomed by more than a few individuals, and would also be costly.

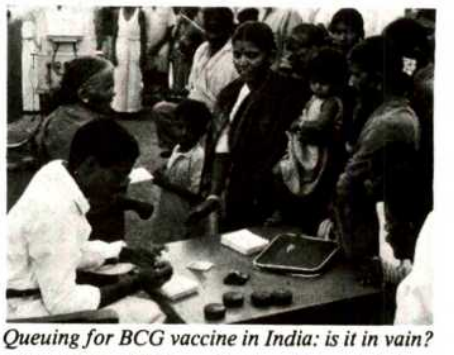
If we accept that some universities will be much more devoted to vocational teaching and less to research than others, then only in a proportion of our universities need the situation be treated as urgent. These urgent cases could have a retiring age of 60 (with full pension) introduced if only temporarily so that a more normal flow of young academics could be reintroduced. I believe the overall cost would be tolerable.

●See page 552 for the legal position on short term contracts in the UK

news in brief

US scientists increase estimates of fluorocarbon survival rates: Research workers with the National Oceanic and Atmospheric Administration have used air samples taken from a global network of monitoring stations to conclude that flourocarbons emitted from aerosols and other sources survive for at least 30 years in the lower atmosphere, considerably longer than previous estimates of the minimum lifetime. The scientists say that the longer periods predicted when their sample data were applied to theoretical models of fluorocarbon behaviour "indicate that fluorocarbons do not undergo significant reductions in the lower atmosphere due to rain-out, fall-out, or chemical reactions, and thus are free to diffuse up into the stratosphere relatively undiminished".

However the scientists also found that the concentration of nitrous oxide fluctuates in the atmosphere, rather than demonstrating any steady growth. From this they have concluded that the potential threat to the ozone layer from gas given off as the result of massive applications of nitrogen fertiliser may not be as great as some have feared. "We had expected to see a steady upward trend in this chemical, corresponding with large increase in the nitrogen fertiliser, but no such trend was observed", said Mr Walter D Komhyr of NOAA's Geophysical Monitoring for Climate Change Programme in Boulder, Colorado.



US refuses to lift ban on pesticide: Despite pleas from representatives of southern states that the health hazards of the fire ant outweighed the hazards of a pesticide, Mirex, capable of controlling the ants, the US House of Representative last week refused to lift a ban imposed on the pesticide in 1977 when it was suspected of causing cancer. Some delegates argued that the known dangers of the ant, which invades the homes of the poor and can inflict a potentially dangerous bite, should take precedence over the unknown hazards of cancer. But they were outvoted by those who felt the need, in the words of representative E de la Garza of Texas, "to take the road of caution and not risk irreparable damage to people and the land".

At the same time, the House voted by 278 votes to 121 to give Congress the power to veto future pesticide regulations issued by the Environmental Protection Agency, although this has not been agreed by the Senate and is opposed by the White House.

MRC proposes less job security for researchers: The UK Medical Research Council has proposed eliminating its "tenure track" and will try to make all tenured jobs competitive on the open market. Under the proposed system a new researcher would be hired on a five year contract with the possibility for a three year renewal but there would be no automatic tenure procedure — individual researchers would compete with outsiders for the tenured jobs that became available. The Association of University Teachers, the trade union that represents the researchers is opposing the move. The present arrangement has five-year limited term contracts with a 75% chance of tenure at the end. It was opposed by many researchers when it was introduced in 1974 as a redundancy procedure that "permitted the MRC to lay off 25% of its annual cohort every year". The MRC was "not prepared to comment at the present time" on the new proposal.

University of Grenoble spectrometry lab occupied: The laboratory of physical spectrometry at the University of Grenoble has been occupied since 14 November by 15 technicians protesting a reduction in their pay of between 20% and 32%. The technicians, all highly skilled with 15-20 years of research experience, fell victim to a complex administrative decision on 1 November which prevents them from receiving pay from two sources — the university and the government — an arrangement that has existed for 20 years. The laboratory employs 130 researchers, technicians and administrators all of whom are in support of the technicians. The lab's 85 physicists have lobbied the university administration and last Friday a one day full scale occupation of the administration building was held in an attempt to bring about negotiations. The matter is now under discussion.

New TB vaccine needed in India: The BCG vaccine used world-wide against tuberculosis has been found to be ineffective in cases of lung TB in India. This is the finding of a major seven year study carried out by the Indian Council of Medical Research in conjunction with the World Health Organisation. The study has found, however, that the vaccine still affords protection against brain and bone TB. The revelations come at a time when the incidence of TB is showing a sharp upturn and the implications of the study extend to other Third World countries. There are an estimated 10 million TB victims in India with 2 million cases known to be infectious. Along with other Third World countries India is now confronted with the complex problem of evolving an alternative to the BCG. *B. Radhakrishna Rao.*

Queuing for BCG vaccine in India: is it in vain?

UK national anti-nuclear campaign launched: The first nationally coordinated extra-parliamentary anti-nuclear campaign in Europe was launched at a recent meeting of 600 activists in London. UK groups expected to ratify the campaign's constitution represent the full range of UK political opinion and include the Conservation Society, the Ecology Party, The Young Liberals, the Socialist Environment and Resources Association, the Socialist Workers Party, the National Union of Miners and local groups throughout the country. The campaign aims to reduce energy demand through conservation measures, to replace nuclear power with alternative energies and to guarantee employment during the changeover. Convenor Tony Webb said that the campaign would also focus on the witholding of information by the nuclear industry. "We have been calling for many months for the safety reports on both the AGR and the proposed PWR without success. Secrecy in these matters only confirms the widespread belief that the technology has not been designed for safety and is in fact extremely hazardous."

In the meantime a new UK study (*Decision Making for Energy Futures, A Case Study of the Windscale Inquiry*, Macmillan) has been published this week that is sharply critical of government policy on information. Calling for a freedom of information act authors argue that access to information, "a fundamental axiom of democracy", is a concept "alien to much twentieth century practice in the United Kingdom". And in a related development, the UK has refused to pay its share of £6m to fund an EEC research project to study the controlled meltdown of a Harrisburg type reactor at the Supersara pressurised water reactor in Northern Italy. Government officials say that the cost of the experiment does not justify the probable results.

US nuclear industry wins 1979 Doublespeak Award: The US National Council of Teachers of English has awarded its 1979 Doublespeak Award for the most appalling public use of the English language to the nuclear power group at Three Mile Island. Out-distancing a record number of nominees for the prize, the officials at Three Mile Island were cited for inventing "a whole lexicon of jargon and euphemisms" that played down the danger. Explosion became an "energetic disassembly", a fire "rapid oxidation" and a reactor accident a "normal aberration".

Berufsverbote continues in spite of resolutions

West German campaigners against Berufsverbot are planning to mark Human Rights Day, 10 December, with a petition to the Federal Chancellor, asking that the promised "liberalisation" of employment policy be implemented. **Vera Rich** talked to a leading member of the campaign about the effect of Berufsverbot on academic life.

BERUFSVERBOT is the denial of professional employment in the government service to persons of allegedly left-wing views. It affects West German universities and academic institutions because the funding of such bodies by the state means that their staff are "state employees" — in the same category as train drivers and postal clerks. Nevertheless, — and rather strangely in view of Germany's previous experience of political disruption of academic life during the 1930s — it was only relatively late in the anti-Berufsverbot campaign that certain universities and academic bodies began to take a stand on Berufsverbot.

> ❛ the social-liberals are convinced that Berufsverbote must end — but it still hasn't stopped ❜

In recent months, resolutions condemning Berufsverbot as a threat to academic liberty have been passed by the senates of the Universities of Oldenburg, Bremen, and Bielefeld, and the Deutsche Gesellschaft für Sociologie, amongst others. In the words of the Bielefeld protest (17 January 1979), the "autonomy of scientific work guaranteed by the German Federal Constitution forbids any attempt to exploit the scientist's status as a civil servant, to supervise his scientific activity by means of methods which are alien to science, or to derive restrictions on scientific activity from the loyalty and allegiance owed by the civil servant". The present practice of "screening and punishment for political beliefs", said the senate, "contradicts the liberal and democratic principles of our constitution," and, together with the administrative decrees on which it is based, "must be declared null and void".

Nevertheless, within a few weeks, Jan Priewe, selected by Bielefeld University as assistant professor of sociology was subjected to an *Anhorungdverfahren* (interrogation process) based on alleged left-wing activities more than five years previously.

Dr Andreas Dress, a leading campaigner against academic Berufsverbot, told *Nature* that it was precisely this screening process which was to have been "liberalised", but that "in fact almost nothing has changed. What we wanted was an end to the involvement of the *Verfassungsschutz* (Security Service) in job placements". In his own *Land* (province) of North-Rhine-Westphalia, for example, applicants have to fill in a form giving all their addresses for the last five years. This list then goes on to the *Verfassungschutz* computer, "proving," he said, "that the state government does not trust its citizens. But in a democracy, the state exists for the good of the citizens — and the Federal Republic of Germany is a democracy! This convinced the social-liberals that the practice must end".

"But it hasn't stopped," he added, "which is why we have organised the current protest. And even if it did officially stop, the personnel section could always pass on addresses to the *Verfassungschutz*. Still, it would be something if the practice were stopped at least officially."

"We are not arguing about genuine security checks," he went on. "We accept that they have to exist. But security can go too far. One politician, for example, justified Berufsverbot on the railways by noting that, during the Nazi occupation of France, French resistance railway workers had been able to half the whole country's rail traffic!"

Within the universities, Dr Dress explained, there is no over-all policy of screening one faculty more closely than another — sociologists, say, more than mathematicians. Some institutions, however, seem more at risk than others. Thus in the Max-Planck Institute of Biology, Chemistry and Physics in Göttingen, screening procedures do not seem to have been applied.

On the other hand, certain universities — Bielefeld included — seem to have more than their fair share of Berufsverbot cases. This, explained Dr Dress, is a result of the more liberal and open-minded attitude of such universities to innovations in course structure and content. Potential victims of Berufsverbot, he said, are less likely to apply to highly traditional establishments, either because they feel they would have no chance of acceptance, or simply because that particular milieu does not attract them. He cited the example of Horst Eckhart Gross, a victim of Berufsverbot screening when he applied for a post at the University of Oldenburg. Previously, Gross had directed a Bielefeld research project on the non-academic job deployment of mathematicians.

Of university cases of Berufsverbot, said Dr Dress, some 80% related to alleged past or present membership of the Communist Party or the "Spartakus" Marxist student union — both, he stressed, legal organisations. Some 10% of cases, mostly in Bavaria, relate to left-wing Social Democrats, and the remainder to miscellaneous left-wing groups. Formally, Berufsverbot should also cover far-right extremists, but according to Dr Dress such cases virtually never occur.

To date, Dr Dress knows of some 4,000 Berufsverbot interogation procedures. These involve prolonged waiting, and, in some of the German *Länder*, such as Bavaria, those undergoing investigation are not allowed to use the services of a lawyer, while in North-Rhine-Westphalia, the right to legal assistance was won only after "a long struggle". Out of the 4,000 cases some 3,000 ended either with reinstatement in the desired post, or else in the applicant abandoning his claim and taking a job in the private sector. Some 1,000 clear cases of Berufsverbot remain on the campaigners' files. However, Dr Dress went on, academics have no "private sector" to go to.

The anti-Berufsverbot campaign assesses all alleged cases very carefully. Problems of student activists expelled for poor academic performance cannot strictly speaking be considered as Berufsverbot. Nor can the recent case — described by *Die Welt* as "grotesque" — of a biologist charged under the German Official Secrets Act for having given his East German brother-in-law an offprint of one of his openly published papers — this was a technical breach of the law. To the anti-Berufsverbot campaigners, it is important that all provocation be seen to come from the official side. "We are really only interested", said Dr Dress, "in cases where the authorities state in writing that the person is banned from employment on political grounds only. Then we can fight."

> ❛ over 70 million DM has been spent in counter-propaganda. ❜

The authorities, incidentally are not slow to take counter-measures against the damage done to their image abroad by the anti-Berufsverbot campaign. Dr Dress recalled that in April of this year, the Christian Democrats tabled a question in the Federal Parliament, demanding to know what the ruling Socialist-Liberal coalition had done to neutralise the influence of the campaigners. To date, according to the official reply, over 70 million DM has been spent in counter-propaganda, mostly among journalists in foreign countries. It is perhaps for this reason, Dr Dress concluded, that initiatives from the campaigners, such as the establishment last February of the "Heinrich Heine Fund" for victims of Berufsverbot, receive little publicity abroad. □

Nature Vol. 282 6 December 1979

Brazil: running on alcohol

Brazil leads the world in the development of alcohol as a fuel for transport. But has it really found a way of appreciably reducing its dependence on oil? Maurice Bazin reports.

THE Brazilian government is plunging into a programme to convert all of its automotive transport to alcohol combustion within the next few years. The technical feasibility has already been proved, and several fleets of government vehicles already operate on pure ethanol.

The PROALCOOL programme was launched in 1975 in response to the world wide increase in oil prices, in an effort to contain Brazil's record US $45 billion foreign debt. Domestic oil production accounts for only 16% of consumption, the rest being imported — almost exclusively from the Middle East — and refined in Brazil.

Ethanol (ethyl alcohol) is produced in Brazil from sugar extracted from sugar cane. Extensive cane fields dating back to colonial days cover the coastal north-east of the country; but these fields have very low yields. The landowners, referred to as 'colonels', reign over their peasants through armed 'captains'. Salaries remain below US $2 a day and never cover the peasant's debt at the general store - which is owned by the colonel. Nowadays, 80% of sugar production comes from the more developed state of São Paulo to the south where agribusiness organisation prevails.

Alcohol production could currently satisfy one-third of Brazil's automotive needs if all private cars were run on pure alcohol. Brazil has in fact been using 'gasohol', petrol mixed with alcohol, since 1931, when the addition of 5% alcohol to petrol was made compulsory. Today, the mixture is not uniform throughout the country, being higher in the states with higher alcohol production, and reaching a maximum of 20% in São Paulo. Until 1975, the mixing proportions were not dictated by practical considerations, alcohol being dumped into petrol as an economic buffer for excess sugar production when international sugar prices dropped.

Some economic experts are apprehensive that the PROALCOOL programme will lose impetus if world sugar prices start rising again. They insist that to make the technological option irreversible and independent of the fluctuations of the international commodity market, new distilleries should be built which operate directly from raw cane, bypassing sugar production and storage. The Institute of Sugar and Alcohol (ISA) which administers PROALCOOL has indeed approved the construction of 87 such new 'autonomous' distilleries. But it also approved the construction of 139 standard distilleries, which will double the present number of distilleries operating from sugar as an intermediary. This decision leaves some doubts as to the earnestness of the government's commitment to a fully independent alcohol program.

Alcohol production has increased dramatically in the past few years. In 1976-77, 600 million litres were produced; in 1977-78 production reached 1.5 billion litres and has risen to over 3.5 billion litres this year. The ISA announced that "the sum of the already operating installations and of those projects already approved or under consideration should produce over 5 billion litres of alcohol. We can be assured of an overall production of 4 billion litres in 1980, which will guarantee the 20% level for the mixture of alcohol with gasoline". The goal for 1985 is 10.5 billion litres.

One problem with this rapid increase in production is storage. Due to a miscalculation by ISA, storage capacity was found to be inadequate this spring. As a result, distilleries in São Paulo are threatened with having to halt operations, and Petrobras, the national company controlling the petroleum industry, is hastily renting out its petrol storage facilities to store the alcohol presently being produced. Furthermore, the government authorised the export of 500 million litres of alcohol, at a price double that of imported oil.

Up to 20% ethyl alcohol can be mixed with petrol without any engine modification, and the optimum mixture, which minimises fuel consumption , occurs with 15% alcohol. Brazil pioneered the study of alcohol engines in the 1920s. For the past ten years, the Brazilian Air Force Technical Institute has investigated the use of straight ethanol in modified automobile engines, and each of the foreign companies that control the Brazilian automobile industry (Volkswagen, Fiat, Ford and Chrysler) has developed new alcohol-powered engines for passenger cars.

Existing petrol engines are already routinely modified in São Paulo for the Volkswagen 'beetle' and the Brasilia model. The changes are few, and currently cost about US $350 per car. The work is done in standard engine overhaul shops approved by the Ministry of Industry and Commerce. Since alcohol has a higher vaporisation temperature than petrol, the incoming air must be preheated to at least 70°C to insure complete fuel vaporisation. This is usually achieved by passing the air through a jacket around the exhaust system, but other schemes using the engine oil in a preheating jacket are also being investigated. These engines will not start when cold, so a small auxiliary petrol reservoir must be installed to start the engine on pure petrol.

Wania Sandis Dell 'Amico

Refuelling on 'gasohol', a petrol-alcohol mixture used in Brazil since 1931

As well as testing the use of straight ethyl alcohol in modified automobile engines, the Air Force Technical Centre has engaged in a vast public opinion campaign. It organised several public demonstrations two years ago including a 'National Integration Tour' during which three test vehicles covered 8000 km in tropical regions. Car races, normally prohibited in Brazil, have been specially authorised to test new ethanol-powered models. Brazilian-built Fiats and Volkswagen sedans (Passat) were run continuously for two weeks, covering more than 100,000 km without problems. In these and other competitions, racing drivers showed enthusiasm for the engines, finding they could reach higher mean speeds than were possible with the equivalent petrol-powered models. They discovered experimentally that the best performances were obtained with an engine temperature 10–15°C *cooler* than the gasoline engines. This developed a higher torque, along with improved engine durability. The only technical problem not yet fully tested is corrosion.

No systematic study of pollution caused by ethanol combustion has been undertaken by official agencies. But it is clear that alcohol is both lead-free and sulphur-free to start with; while the lower engine operating temperature is liable to produce less polluting compounds.

But PROALCOOL pollution problems appear dramatically at the source. Distilleries are always built beside rivers,

Maurice Bazin is a science journalist specialising in Latin America. He is advising the Brazilian government on the teaching of physics.

0028-0836/79/490550-02$01.00

©1979 Macmillan Journals Ltd

into which they dump the stillage, or 'bottom slops', coming out of the first distillation column at a rate 12 times (by volume) that of the alcohol produced. The total output of stillage in Brazil is equivalent in biological oxygen demand to the untreated sewage produced by a city of 200 million inhabitants. Studies at the Copersucar research centre in São Paulo show that the high potassium content of stillage is responsible for killing both fish and aquatic flora. Although stillage can be converted into fertilizer or simply spread back on the fields after 'lagooing' for a while, this is hardly ever practised in Brazil, where distillery owners are not bound by any environmental regulation.

The early political commitment to use alcohol as a fuel has led Brazil to a definite technical lead. National pride ran high in October when Frank Press, President Carter's adviser on Science and Technology, who was touring Brazil in an alcohol-powered car, declared: "This is not an aid mission. Our visit is to initiate a mutually beneficial cooperation. Brazil is ahead of the whole world in the area of alcohol fuel, and the United States is interested in the PROALCOOL programme." At the same time the Brazilian Minister of Industry and Commerce, accompanied by the president of the Alcohol and Sugar Institute, was in Bagdad to sign an agreement of technical cooperation with Iraq which includes an offer of Brazilian technical know-how.

A recurrent theme among planners and politicians alike is the drive for technological independence through the use of those Brazilian technologies which are best established. "We have many raw materials from which we can extract alcohol," says Jair Carlos Melo, professor of Energy Resources at the Federal University of Minas Gerais in Belo Horizonte. "We should not stimulate national competition between them but rather select those which are immediately usable. This attitude will avoid our facing in the future the same problems with PROALCOOL which we now face with the nuclear energy programme: finding ourselves dependent upon foreign technology." This implies emphasis upon sugar cane, however, and reinforces the conservative agrarian social structure in the Brazilian countryside, and increases the power of the sugar 'colonels' and the owners of mills and distilleries.

Plans to diversify the sources of ethanol are being made, however, at least on an experimental basis, in the Ministry of Agriculture. Ethanol could be produced by the fermentation of wood. The cost of a pilot plant with a capacity of 100,000 litres per day is officially estimated at US $20 million, "which is less than our daily expenditure for oil imports," says the Ministry's general secretary. But the plan is far from complete; the choice of a technology best-adapted to Brazilian wood will be made by a semi-private company still to be incorporated.

The other highly promising alternative for alcohol production is 'mandioca', the plant from which comes tapioca. Mandioca has the great advantage over sugar cane that it can be grown in poor soil. Traditionally it has not been grown on large plantations by powerful landowners, like cane, but has remained the poor man's foodstuff. Only one experimental distillery operating from mandioca exists at present in Brazil. It was built by Petrobras in the State of Minas Gerais as a demonstration plant on an industrial scale, and produces 60,000 litres per day. Ten other projects have been approved by the government, several to be run by universities. One is also an attempt to decentralise energy production: the alcohol from mandioca will be used to run a turbine and produce electricity in the northern state of Ceará. Without specific government subsidies, it appears that private entrepreneurs do not dare as yet to invest in the construction of mandioca distilleries.

The development plan for the PROALCOOL programme relies upon the investment of US $1.75 billion in five years. So far, a loan of $1 billion has been obtained in London but the Brazilian Central Bank will free only $350 million per year for the programme, keeping the balance in reserve. That sum is at present almost entirely devoted to financing new distilleries and modernising existing ones.

Some still have doubts

Vocal critics of the programme are found among economists and sociologists concerned with overall agricultural development. They point out that with presently existing technology sugar will be the only prime material for the production of alcohol during the next five years, and the present area under sugar cane must be more than doubled to meet the goals of the programme. Sugar cane demands fertile terrain and often special irrigation. Unless there is overall planning and coordination of agricultural production, easily available financial incentives for sugar cane planting will increase the social imbalance of Brazilian society. Sugar cane, now 'alcohol cane', could easily displace much-needed food crops and the regional imbalance and social tensions already characteristic of the Brazilian countryside will be exacerbated.

Trades unions have taken advantage of the combining liberalisation of the military regime to promote debates about the government's options for development. The Federation of Agricultural Workers of the State of São Paulo and the Distillery and Refinery Worker's Union are conducting "forums of the unconsulted", warning that the extension of the sugar cane agro-industry will "increase the inequalities in land use and ownership, in income distribution and in the distribution of the benefits of progress".

Even some state governments reject the grandiose schemes which the federal government has planned for them. Thus the Agricultural Secretary of the state of Parana, immediate neighbour of São Paulo to the south, plans to authorise the construction of only 20 new distilleries rather than the 40 of the federal programme. "I reject the megalomania of the State of São Paulo", says Reinhold Stephanes, announcing that production per distillery would be limited to 120,000 litres of alcohol per day instead of 400,000 as in São Paulo. Five thousand hectares are necessary to produce 120,000 litres per day, and the regulations established in Parana demand that 25,000 hectares be reserved for other crops in districts where distilleries will be located.

The greatest doubt about the whole PROALCOOL programme concerns its ability to contribute to a real reduction in the outflow of dollars, or even to economise upon oil imports. During recent seminars throughout Brazil to consider the country's energy options, several engineering consulting firms have pointed out that the substitution of petrol fuel must be considered in a much broader context than has been done so far. Existing refineries produce fixed, and roughly equal, proportions of petrol, gasoil and diesel fuel. These proportions correspond closely to the consumption of each product. Alcohol, however, would substitute for only one of them. Refining schemes are quite rigid and any modification in the proportions of the final products would require enormous investments on the part of Petrobras.

To reduce its imports of crude oil, Brazil must therefore "wage a global struggle against the barrel", says Sergio Trindade, director of Promon's Technology Centre, a large consulting firm in Rio de Janeiro. In his presentations at national seminars, Trindade has pointed out that Brazil is at present totally dependent upon diesel fuel for its transport; more than 90% of goods being transported by lorry. Maritime transport accounts for less than 3%, although the country has a very long coastline and excellent harvours. The latter have traditionally been used exclusively for exporting cash crops (sugar, cocoa, and coffee) rather than for internal commerce. To reduce seriously Brazil's dependence on imported crude oil, control external debts and achieve what the government calls 'strategic independence', all three components of the barrel must be reduced at the same time. This means that the whole energy consumption pattern of the country must be altered. Small steps are not enough. Trindade would like to see an 'alcohols' programme get under way as part of national energy sources evaluation effort. This is the dominant theme of numerous discussions taking place at present throughout the country with the participation of ministers and scientists to eleborate a new 'Brazilian energy model'. □

Short term contracts: the legal status in Britain

British law on fixed term contracts is unclear. Basic questions, such as 'what is a fixed term contract?' and 'how effective is a waiver clause?' have still to receive satisfactory answers. **Julian Fulbrook** of the London School of Economics, traces the recent legal wrangles.

THE shabby treatment of short term contract workers continues to be a matter of concern. Although in the scientific and university context the exploitation of workers has never reached the depths of casual work problems experienced in the docks or building industry, the existing legal position is far from satisfactory.

Various estimates put the numbers involved at around 10,000 postdoctoral and other short term contract researchers in the United Kingdom. Of course, a strictly legal analysis ignores the wider general debate on tenure and temporary posts. And no one can ignore the desperate plight of highly-trained individuals who have hardly settled into a new position when they are required to forage for the next project, knowing that a new generation of younger researchers will be cheaper to employ. Mr Justice Kilner-Brown remarked in a recent case that the legal profession contains a similar log-jam between pupillage and a tenancy in chambers, but most would-be barristers are quickly snapped up by industry and the Civil Service. No such immediate alternative presents itself to scientists.

In considering the legal position of short term contract workers, it is important to note the threshold qualifications for Unfair Dismissal and Redundancy. The minimum period before a claim can be issued is now 52 weeks of employment for Unfair Dismissal and two years for Redundancy. It is therefore commonplace for a research worker to be fully in employment for a number of years, but at wholly different establishments for periods of months, and never build up an entitlement. The position is perhaps most acute for women who would wish to take up state maternity pay but are unable to stay in one institution for the requisite two years.

The usual legal questions, however, revolve around the nature of dismissal by expiry of a fixed term contract, and the potential waiver by a short term contract worker of his job security entitlements.

It would be an obvious loophole if an employer could evade the statutory protection given to employees against Unfair Dismissal by giving an endless series of short term contracts. The law since 1963, on the whole range of employment protection legislation, has therefore laid down certain rules to stop up this loophole. Unfortunately it can do little to help the worker who, through force of economic necessity, has to move through a variety of employments; however, if his employers are 'associated', the continuity of rights may be maintained. Essentially, in relation to Unfair Dismissal or Redundancy, employment protection exists when any fixed term contract, of whatever length, comes to an end without renewal. This preliminary hurdle passed, the law then turns to the question of whether non-renewal was fair or unfair.

The waiver provision is more complex. To achieve an effective waiver, the contract of employment must be for a fixed term of two years or more. The statute insists on four requirements before the waiver ousts the jurisdiction of an industrial tribunal:

- The waiver must be in writing, in contrast to the general rules on employment law which give binding effect to oral terms.
- The written agreement must be made before the expiry of the fixed term contract
- The dismissal itself must consist only of the expiry of the fixed term contract without its being renewed. For example, if the worker is accused of misconduct or 'not being up to the job', then his remedy is under Unfair Dismissal and the waiver is not a bar to his claim.
- The final requirement has been the basis of confused litigation: the contract must be for a *fixed term* of two years or more.

But what precisely is a fixed term? The legislation is not entirely helpful. Section 49(4) of the Employment Protection Consolidation Act 1978, which gives an employee statutory minimum periods of notice, uses the concept of a *term certain,* whereas all the other statutory provisions refer to a *fixed term.* The significance of this is unclear, but in any event it has been brushed aside in the recent leading case of the Court of Appeal in *Dixon v. British Broadcasting Corporation* [1979] Industrial Cases Reports, page 281.

To understand the importance of the *Dixon* case it is necessary to recall the earlier decision of the Court of Appeal in *BBC v. Ioannou* [1975] ICR 267. Here Lord Denning had said that a fixed term was "one that cannot be unfixed by notice". In other words if there was an express term to allow either side to part company amicably before the stated term, then the contract was no longer for a fixed term. As notice provisions are practically universal in contracts of employment this had the effect of greatly reducing the scope of the exclusion provision. This may have been desirable in some respects, but the case had disastrous consequences overall for the short term contract worker. As a notice provision rendered a 'fixed term contract' simply an ordinary contract, the worker could not claim that he had been dismissed through the expiry of a fixed term. And it would not be possible to qualify for Unfair Dismissal or Redundancy under the head of an ordinary straightforward dismissal, or even under a constructive dismissal, because of course in reality the contract had terminated by the 'effluxion of time'. The short term worker fell into a limbo.

Various Industrial Tribunals and the Employment Appeal Tribunal tried valiantly to avoid this injustice. Now in *Dixon,* the Court of Appeal declares that they were wrong in *Ioannou.* Lord Denning admits engagingly that he admired the ingenuity by which the tribunals were evading his previous definition of a fixed term to achieve a 'sensible result'. He noted the criticisms of many commentators that an employer could always evade the Act by inserting a simple clause 'determinable by one week's notice', and he declared that this could not have been the intention of Parliament.

The details of *Dixon* were that the BBC employed two men in Manchester as 'house services attendants'; Lord Denning thought that this was "a grandiloquent way of describing a commissionaire or a porter". Both were employed under fixed term contracts which, after several extensions, were due to expire "unless previously determined by one week's prior notice in writing on either side". Each employee had signed the extensions which always included the notice provisions. The final fixed term was for only four weeks, but the BBC disputed strenuously that it was for a 'fixed term' on the basis of *Ioannou.* To illustrate the see-saw nature of litigation, it should be noted that the Industrial Tribunal decision followed *Ioannou,* the Employment Appeal Tribunal allowed an appeal distinguishing *Ioannou,* and the Court of Appeal dismissed the BBC's appeal and overruled part of *Ioannou.*

The upshot of the Court of Appeal decision is that a fixed term contract may nonetheless have within it the possibility of termination by notice and yet remain a fixed term contract in law. *Dixon* has therefore resuscitated a number of Originating Applications which, having been earlier knocked out on jurisdictional grounds, are now able to proceed before the Industrial Tribunals.

Paradoxically, the Court of Appeal has increased the importance of the waiver provision. The original rationale behind the redundancy exclusion was explained by Professor Grunfeld, Professor of Law, London School of Economics, as being that "an employee taken on for a fixed period knows from the beginning that his job ends on a certain date . . . The fixed term employee knows what is to come and is therefore in a position to plan ahead for himself". But such a view cannot tenably be expanded to cover an exclusion from Unfair Dismissal. The law at present provides for fair dismissal in relation to lacklustre performance in a probationary period, and the continuance of the arbitrary two-year fixed term rule operates merely as a loophole for an employer to evade the Act.

It is unrealistic to imagine that research workers can individually refuse the imposition of a waiver when there may be hundreds of other candidates willing to take up the post. Of course the practical solution is through collective negotiation to abolish the waiver, but given the lack of unionisation and the ease of importing new research workers, this can only be a long-term aim. Meanwhile, even where a waiver is not utilised, employers mould their contracts to the law; a favourite device is the 21-month contract, which creates the problem of finance over the summer before the start of a new academic post.

An important question arises over multiple contracts: is it possible to amalgamate the cumulative period of a series of fixed term contracts to achieve a fixed term of two years? In *Ioannou* the Court of Appeal, in a part of the judgement that has not been overturned, held that it is only the 'final' contract which has to be considered. Only where this final contract is for a fixed term of two years or more can there be a valid waiver. Although lawyers would normally draw a distinction here between a 'renewal' or a 're-engagement', Lord Denning regarded this as "too fine a distinction for ordinary mortals". His approach was followed in the Employment Appeal Tribunal decision of *Open University v. Triesman* [1978] ICR 524, where the employee was offered a post as a lecturer for a fixed period of 18 months.

However, this 'straightforward' view has strange consequences. If an employee starts with a 21-month fixed term contract and is therefore unable to make a waiver, but then goes on to a two year renewal with a waiver, he will be unable to claim a redundancy payment. The first period will be blotted out, and no claim is possible.

This and many other legal puzzles leave the law in an uncertain state. There is still the faint chance of an appeal in *Dixon* to the House of Lords changing the law all over again, or even the possibility of major legislative change by the present government which has as yet given no precise indications as to the parameters of planned amending statutes. The only certainty is that the present law is in urgent need of an overhaul to resolve the waiver dilemma. Although this of course will do nothing to change the demand for short term contract workers, it may prevent some of the anxieties suffered by them. □

Carnivorous practices

THOMAS H. JUKES

THE subject of meat eating is one that entrances gourmets, repels vegetarians, and attracts anthropologists. It has fascinated physiologists ever since the experiments on the fistulated stomach of Alexis St Martin by William Beaumont.

Something new happened recently: it started in a restaurant in Washington that was serving Pennsylvania rattlesnake meat to its patrons, thus reversing the balance of nature in which snakes bite hominids. Incredible as this would have seemed even as recently as 30 years ago, this venomous serpent is protected as an endangered species. An employee of the US Fish and Wildlife Service wrote a letter to the restauranteur, tactfully pointing out the act of trespass, whereupon the restaurant switched to Texas rattlesnakes for serving to its herpetophagic patrons.

All seemed well at first — except for the Texas snakes — but perhaps a conservationist intervention will soon be organised on their behalf. However, the news leaked out, whereupon the offending civil servant was fired by order of the Secretary of the Interior. A thunderous protest against the firing was mounted by lovers of Pennsylvania rattlesnakes and haters of dictatorial cabinet members, so that the Secretary hastily re-hired the snake-protector, bowing to the uproar from Congress, and from environmentalists, who are still seething over the betrayal of the snail darter.

It was time, I thought, for some general comments on meat eating, a mode of sustenance that involves a complex pattern of approvals and taboos. Probably none of us is without prejudice, distaste or downright rejection for some forms of meat that are relished by ethnic groups to which we do not belong. Nutritionally speaking, the proteins of various meats are quite similar in amino acid content, and are superior in this respect to vegetable proteins, but this does not affect their acceptance or rejection.

Avoidance of beef in India is one of the best-known taboos. One theory is that it originated when Brahmins renounced cattle sacrifice to improve their position in political rivalry with the Buddhists. The shunning of pork is centered in the Middle East, and the feelings of rejection can be intense enough that martyrs have chosen death rather than submitting to being forced to eat pork.

It is often firmly asserted that the Jewish ban on pork originated as a protective measure against trichinosis that was based on intuitive and shrewd trial-and-error observations. This is contradicted by Simoons, F.J. *Eat Not This Flesh* (University of Wisconsin Press, Madison, 1961), who points out that *Trichinella* was unknown until the nineteenth century and was considered to be a harmless organism for 25 years after its discovery. It is unlikely that spoilage of pork by heat is the reason for the rejection. Temperatures in the Middle East are no higher than in many countries such as Southeast Asia, where pork has been a prized food for many centuries.

The evaluation of other possible reasons for the ban, such as distaste for the uncleanliness of pigs, is complicated by the fact that Jewish laws also banned the eating of 30 kinds of animal including some comparatively tidy creatures, such as snakes. Chickens, however, are on the approved menu, even though their eating habits are at least as unsanitary as those of pigs. Americans and Western Europeans, who avidly swallow live oysters, would recoil from eating dog, which is relished in Central Africa, China and Southeast Asia.

The eating of frogs and snails was formerly used to whip up feelings of xenophobic prejudice in England against the French. In riposte, the English were called 'limeys', but it seems difficult to arouse antipathies based on the consumption of fruit, and, in any case, limes prevent scurvy.

The new approach to the avoidance of foods, including meat, and especially beef, is based on arousing the fear of cancer. I shall discuss this, and more meat-eating matters next time.

Researchers Information Exchange

SIR, — Neither your editorial *Time for a policy on scientists' jobs* (1 November, page 1) nor the report by Joe Schwartz on *Portrait of the out-of-work scientist* (1 November, page 7) deserve to pass unnoticed. It is high time that the maximum of serious attention was given to the undoubted crisis which has developed in medical research and in research in other fields. The case of Dr Ann Simmonds and the Purine Laboratory at Guy's Hospital is only the tip of an uncompromising iceberg, that in the not too distant future is certain to confirm at last the United Kingdom's position as a third rate economic and scientific power, with a complement of first rate scientists, and scientific opportunities going to waste. Now is the time to ask "How long is it?" until that future comes to pass.

Some months ago the Association of Researchers in Medical Science committee received a very stony answer from the Department of Education and Science when they entered a plea to the Secretary of State to initiate a major inquiry into the scientific research sector (in a time of constraint and crisis), with particular reference to the conditions of employment of scientists and support staffs. In the meantime researchers' organisations, trades unions and campus opinion has been mobilised to publicise the plight of many researchers and scientists (in all disciplines).

The need to act in order to protect and develop conditions of work now seems a necessary distraction that research workers must pursue for their own survival and for our scientific future.

Government complacency and indifference in these matters is no longer defensible. In fact, some gesture from that quarter might redeem the situation before it gets really out of hand.

May I, through your columns, appeal to researchers and scientists to press energetically for a major review of the whole research and development sector, by the combined efforts of government, scientific and professional agencies. If our current economic straits do not allow the full panoply of review, at least a start must be made to identify problems and solutions so that scientific research policy can once again be adequate and informed. If action is not initiated soon we must accept irretrievable losses and delays to scientific progress, and technological and social applications. Can we bear to estimate our regret in five or ten years time by not having taken a positive stance now?

In the immediate future researchers and scientists must take steps to collaborate and coordinate their efforts in what is likely to become a bitter political battle if no firm action to seek just remedies is taken.

To this end a group of researchers (including myself and Dr Simmonds) have already established and gathered support for a *Researchers Information Exchange* to collect, analyse and distribute information on all aspects of research and development, relating to employment and conditions of work, and in the broader area of organisation, cooperation, funding, planning and policy-making. A recent meeting of RIE participants at Leicester University voiced the need for unified policies in the field of research, and it is to this end that readers and colleagues are urged to lend their support to this venture as a first stage in self-help to ensure the continued existence of a viable scientific community in this country.

Yours faithfully,

STEPHEN ROBERTS

Loughborough University, Leicestershire, UK.

Life-time of research for minority only

SIR, — You are right to say (1 November, page 1) that hard thinking is needed about the nature of scientific careers. As I have argued elsewhere, however (*New Scientist*, 17 May 1973) one of the foundations for such thinking must be that research alone cannot provide a life-time career for any but a minority. Until this unpleasant truth is more widely recognised, we shall continue to have the waste and personal tragedy which you illustrate in the same issue as your leader.

Yours faithfully,

D.W. BUDWORTH

London W4, UK.

Alexander Lerner: a call for action

SIR, — We are extremely disturbed about the case of the distinguished Soviet scientist, Professor Alexander Lerner, who for eight years has been incurring the displeasure of the Soviet authorities because he applied for permission to emigrate to Israel. Professor Lerner was Director of the Department of Large Scale Systems at the Institute of Control Sciences, and among his publications is a well known text book, *Fundamentals of Cybernetics*, which has appeared in many languages.

Following his application for a visa he was: dismissed from his post and the Communist Party and forbidden to teach any students; expelled from the Editorial Board of the journal *Automation and Telemechanics*; removed from the public office of Chairman of the Scientific and Technical Committee of the University of Moscow. An attempt was also made to remove him from the post of local deputy Chairmanship of the Committee of the International Federation on Automation Administration which was rejected by the Federation.

After selling 40,000 copies, his book *The Beginning of Cybernetics* was taken out of production and his contract for this publication cancelled because of "mistakes in the manuscript", although a translation was published in many countries and it was recommended for the Competition of Best Books in 1967. The book *Optimal Heating of Metals* of which he was the scientific editor and one of the authors, was published in 1972 by the Metallurgy publishing house without his name being mentioned and without any reference to his works which are of fundamental value in this sphere. He has been prevented from attending conferences both within his own country and abroad.

Professor Lerner's daughter received a mathematics degree at the age of 15. In 1974 she and her husband were allowed to emigrate to Israel where they now live with their two children. Professor Lerner who is 66 years old has never seen his youngest grandchild.

We are endeavouring to ameliorate the fate of this man who is isolated from his scientific colleagues and his work. His many interests clearly lie within those fields covered by the International Federation of Automatic Control (IFAC). We hope that these international scientific bodies such as IFAC will show they have a clear duty to defend the rights of scientists working in their subject area. We therefore publicly call upon the IFAC Executive Council and National Member Organisations to consider seriously the fulfilment of their obligations in the case of Professor Lerner.

Yours faithfully,

PETER ARCHER DAVID SHEPPARD
for the parliamentary contingent

NEVILL MOTT A.H. VAN DEN HEUVEL

The Lerner Circle, London NW3, UK.

European ingenuity in particle physics

SIR,—We write to correct some of the more grossly misleading impressions generated by the careless journalism of your article entitled "Can Yankee ingenuity keep US physics on the ball?" (1 November, page 2).

The reference to PEP as the machine "expected to be the first to discover the Z°" is obviously, from its context, a mistake for the antiproton-proton ($\bar{p}p$) collider now under construction at CERN. This machine is made possible by European ingenuity displayed in the development of beam 'cooling' techniques — stochastic cooling was invented at CERN and electron cooling at Novosibirsk in the USSR. The feasibility of cooling $\bar{p}$ beams has been demonstrated at CERN and the $\bar{p}p$ collider project quickly launched to use the SPS ring as a store of both $\bar{p}$ and p. The similar project at Fermilab which you mention is totally dependent upon these techniques.

The method proposed by Richter to achieve collisions of 40 to 50 GeV electrons and positrons is indeed relatively cheap as it depends upon the existence of an expensive two mile long accelerator at SLAC, built in the late 1960s and the only one of its kind in the world. We applaud the ingenuity of this proposal and hope that the very formidable technical problems can be overcome. However, even if successful, this device cannot attempt the fundamental research for which LEP is deliberately designed; that is, not only to make a complete study of Z° physics but to allow the most searching investigation of the weak, electromagnetic and strong interactions, performing vital tests of the gauge theory approach — such as the one due to Salam and Weinberg — which promises a unified understanding of these forces. These objectives require positron and electron energies approaching 100 GeV, not attainable at SLAC.

The last decade has been a time of dramatic advance in our knowledge and understanding of fundamental physical processes and we welcome the enterprise and ingenuity being exercised by physicists and engineers, both in Europe and the US, to bring nearer the crucial tests so eagerly awaited.

Yours faithfully,

R. J. CASHMORE
J. H. MULVEY

Department of Nuclear Physics, Oxford, UK.

news and views

Differential attack

from Robert W. Cahn

THE essentially empirical science of chemical etching, used as a routine tool by the material scientist to reveal the microstructure of mineral samples, has developed in some unexpectedly sophisticated ways. One is the recent development of a thin-film ultramicrosieve (Kitada *J. mater. Sci.* **14**, 2765; 1979), the latest in a line of filters whose unlikely origins lie in an observation made years ago that chemical etching could reveal the damage tracks left by the passage of nuclear fission fragments through thin mica sheets.

This story begins in 1961, when R.M. Walker and P.B. Price at the Central General Electric Research Laboratory in Schenectady discovered that these damage tracks were revealed by chemical etching which pierced minute, uniformly-sized holes through the mica. Other minerals were soon found to behave similarly, and other forms of radiation found sometimes to yield etchable tracks. Walker and Price, aided by R.L. Fleischer, over the next few years applied this differential etching method to many problems in geochronology, planetary physics (the study of meteorites in particular), palaeontology and nuclear physics. The field has become large enough to achieve that ultimate accolade, a journal of its own.

The early mica work came to the attention of S.H. Seal, a clinical cancer researcher at the Sloan-Kettering Institute who needed an ultrafilter to hold back cancer cells from suspension in blood; nothing he had tried would do the trick. Price's irradiated and etched mica foils were just right (the holes were all 3–4 μm across) but the foils were too fragile. At this point, Fleischer found that a polycarbonate polymer could be substituted for mica and had better mechanical properties. Thus began the manufacture of GE's 'Nucleopore' biological filters, which, among other uses have a role in cancer diagnosis. The filters were described by Fleischer, Price and Symes in *Science* (**143**, 249; 1964), and the steps in this weird progression from fission damage research to clinical instrumentation are traced, step by step, in that excellent survey, *Applied Science and Technological Progress* (313, NAS, Washington, 1967).

This case-history has evidently influenced subsequent research at GE. For instance, W. Desorbo and H.E. Cline, who were investigating directionally solidified eutectics, consisting of parallel metallic rods in a matrix, with a view to their use in jet engine turbine blades, found that differential etching left the rods protruding clear of the matrix. Porous metallic replicas made from such etched samples performed neatly as microsieves (*J. appl. Phys.* **41**, 2099; 1970).

Filters with holes a few microns across are considered coarse nowadays (too coarse, for example, for the isolation of airborne smokes), and a new approach has now shown how to make filters with submicron apertures. M. Kitada (*J. mater. Sci. op. cit.*) co-evaporated gold and germanium in vacuum onto sodium chloride crystals. Films 50–500 nm thick were evaporated, at or near the eutectic composition of 12 at% Ge. Germanium was deposited as round grains 20–250 nm across, depending on alloy composition and substrate temperature. The films were floated off in water and attacked by an iodated mixed-acid etchant, which selectively removed the more reactive germanium. Since the germanium grains grow in columnar fashion through the film thickness, removal of germanium leaves minute pores right through the residual gold films and the result is a thin-film ultramicrosieve.

Another form of selective attack which is not only technologically valuable but scientifically intriguing, is the vertical etching of silicon. This technique, which for several years has been quietly developed within the semiconductor industry, is now beginning to find applications in other scientific fields. An excellent account of the technique, its scientific basis and recent very various applications has just been published by D.L. Kendall (*A. Rev. Mater. Sci.* **9**, 373; 1979) who regards it as a 'whole new way of structuring and using a solid material'. The essential fact is that extremely narrow, deep grooves with depth-to-width ratios exceeding 100:1 can be etched in silicon. It is only necessary to start with a monocrystal slice accurately parallel to (110), and to prepare an oxide surface mask with narrow gaps precisely parallel to the (110)/(1$\bar{1}$1) intersection. Etching is very much faster in the [110] than in the [1$\bar{1}$1] direction, because the newly formed (1$\bar{1}$1) plane is quickly covered with an oxide film which severely hinders access of etchant (usually an aqueous solution of potassium hydroxide used at 80 °C), whereas other planes are not thus affected. Any divergence of the surface slit from correct alignment enhances the rate of etching of the sides of the groove.

Whereas it is easy to etch deep ultra-narrow grooves, it is not possible to etch round holes. A regular array of exact 5 μm-square holes has been fabricated by etching two populations of grooves, mutually inclined at 70°, from opposite sides of a (110) slice until they just meet (Bean, *IEEE Trans. ED-25*, 1185; 1978). Other uses include deeply etched solar energy absorbers (effectively thin-layer blackbodies), an elaborate high-area Si/SiO_2 capacitor only about 1 mm square, diffraction gratings efficient for high-order optical spectra and an infrared reflection polariser. The most subtle application is a device for ejecting ink-drops between closely spaced pairs of electrified p/n junctions to charge the drops, which can subsequently be electrically steered to form a printed image. This has cleared the way to computer-controlled printing without moving parts.

A variant on the sieve theme is a selective-ion device for separating ions such as Cu^+, which diffuse very fast in silicon. A thin-walled meander is formed in a silicon slice by etching offset parallel grooves from the two sides; copper will pass selectively through such a silicon membrane, much as hydrogen passes selectively through palladium. If the membrane is oxidised by anodising in hydrofluoric acid, the oxide has pores which can be as small as 1 nm in diameter. These can be used to separate molecules of different sizes: larger pores, for example, can serve as virus filters (Watanabe *et al. J. Electrochem. Soc.* **122**, 1351; 1975; Gregor & Gregor *Sci. Am.* **239**, 88; 1978). □

Probing eukaryotic gene control

from Ron McKay

FOR two decades after the structure of double-stranded DNA had been determined, the difficulty of either establishing or manipulating a DNA sequence made even a descriptive approach to DNA-protein interaction difficult. The recent advances in DNA chemistry have been followed by improved methods of studying the association of DNA with protein and these techniques have provided valuable insights into such interactions as that between *lac* repressor and its operator DNA, the paradigm in this field, and those between ribosomal proteins and RNA. At a different level however, the most striking conclusion of a recent meeting* on this topic was that prokaryote-based rules of genetic organisation cannot completely explain eukaryote gene control.

A brown box

Any functional definition of a gene must include statements covering the mechanisms of transcription, translation, replication and recombination. In eukaryote studies almost all current work is directed towards the question of the control of selective transcription. By analogy with the known control sequences in bacterial genes this has led to the search for common elements in the 5′ sequences flanking the gene. But presentations on *Xenopus* 5S RNA genes, sea urchin histone genes, human globin genes and chromatin reconstruction experiments suggest that the control signals need not be in the adjacent 5′ sequence and the 5′ signals that do exist may not be obvious at the DNA sequence level. Bogenhagen (Carnegie Institution, Baltimore), working with D. Brown, has been asking what sequences of a cloned 5S RNA gene are important for transcription, using the ability of appropriate extracts of *Xenopus* oocytes to obtain precise transcriptional initiation and termination of a cloned 5S RNA gene.

The experiments show that all of the 5′ flanking sequence and up to 50 base pairs into the gene may be replaced without substantially affecting initiation of transcription. It follows that the 5′ flanking sequences and indeed the first 50 bases of the gene itself do not influence the site of initiation. By progressive deletion from the 3′ end of the gene and measuring initiation in the presence of the chain-terminating analogue cordycepin, an intragenic control sequence of 30 base pairs was found. The next step was to insert these 30 base pairs only into a bacterial plasmid and show that the *Xenopus* RNA polymerase III initiated transcription in plasmid DNA 50 base pairs 'upstream' of this sequence in either orientation. So what is this 'brown box' sequence doing? There are a number of possible explanations but Bogenhagen pointed out that 50 base pairs is 170 Å long and RNA polymerase III is big enough to contact both the intragenic promoter and the 5′ initiation point. How many genes have 'brown boxes'? The VA RNAs of adenovirus are transcribed by RNA polymerase III, have a known sequence and are amenable to genetic analysis; these must also be good candidates for intragenic control sequences.

Surrogate genetics

Eukaryote genes coding for proteins are transcribed by RNA polymerase II which has only recently been persuaded to initiate faithfully *in vitro* (Weil *et al. Cell*, **18**, 469; 1979). M. Birnstiel (University of Zurich) reported on experiments where genetically manipulated sea urchin histone genes are functionally assessed *in vivo* by microinjection into the nucleus of a *Xenopus* oocyte. The histone genes occur in repeating clusters each containing H4, H2b, H3, H2a and H1 in this order. In the oocyte only H2a and H2b proteins are unequivocally detected when a plasmid containing all the histone genes is injected. Comparison of the noncoding sequences at the 5′ and 3′ ends of the H2a repeated genes shows conserved regions. The implication is that these regions have a conserved function and the Zurich group is testing whether this is transcriptional control by deleting these sequences and studying RNA transcripts in the microinjection assay. An attractive feature of the system is that H2a may be manipulated while leaving the H2b sequence upstream as an internal control presumably not subject to polar effects. The Zurich group does observe alterations in the amount and size of the H2a transcripts when noncoding 5′ sequences are altered *in vitro* although the possibility that RNA processing may be responsible cannot be excluded.

Both the Baltimore and Zurich groups are approaching the question of what is a transcriptional unit using the same logic, of isolation, manipulation and functional assay. R. Flavell (National Institute for Medical Research, London) in contrast, reviewed the descriptive studies of the deletions that give rise to thalassemias in man. He pointed out that deletions of the delta and beta globin gene sequences alter the expression of the fetal globin genes in adult life even though these fetal genes lie more than 10 kilobases to the 5′ side of the deleted sequences. There is some tentative evidence that these long range interactions may be a *cis* acting effect. We can conclude that in these three eukaryotic systems our traditional view of what constitutes a gene will be changed. In the case of the *Xenopus* 5S gene there is no doubt that an important new means of exerting genetic control has been described.

Chromatin structures

A. Klug (MRC Laboratory of Molecular Biology, Cambridge) reviewed the impressive evidence accumulating for the solenoid model of nucleosome superstructure from neutron scattering, electron microscopy and, surely definitively, from the X-ray patterns of intact nucleosome crystals. The concern of the Cambridge group has been to describe the higher order structure of chromatin. P. Chambon (University of Stransbourg) on the other hand addressed the question of whether the structural arrangements of DNA in chromatin affect gene expression. The DNase I hypersensitivity of active genes first described by Weintraub now seems to be generally true but as Chambon pointed out it is not known whether this is the cause or consequence of gene activity. Nor is it clear what constitutes a 'domain' of hypersensitivity. In the SV40 minichromosome Varshavsky has shown that a region around the origin of replication is highly susceptible to enzymatic digestion because it is not packaged into nucleosomes. Chambon's group has now shown that this open structure can be obtained on reconstituting SV40 chromatin. The importance of this result is that it shows that the DNA sequence is itself responsible for the 'open' arrangement of nucleosomes around the origin. So in this case at least we can conclude that hypersensitivity to nuclease digestion precedes the expression of the viral genome on infection.

RNA processing

J. Abelson (La Jolla) has made progress in characterising the yeast tRNA splicing activity he has described. The possibility that this 'tRNA spligase' may also be an 'mRNA spligase' was raised by the extracurricular reports of intervening sequences in the yeast actin genes both from Abelson's laboratory and from Gallwitz (Marburg). Irrespective of whether the same enzyme is involved in both tRNA and mRNA splicing, the ease and precision of yeast transformation means that this will be an important organism in the study of the biochemistry and genetics of splicing. H. Robertson (Rockefeller University) reported on work showing that the influenza virion RNA polymerase activity captures the capped 5′ end of host mRNA not by splicing but by using the cleaved 5′ oligonucleotides as a primer for transcription.

Ron McKay is at the Cold Spring Harbor Laboratory, Long Island, New York.

*The EMBO Symposium on Nucleic Acid — Protein Interactions was held in Heidelberg on 11-15 October, 1979.

Real genetics

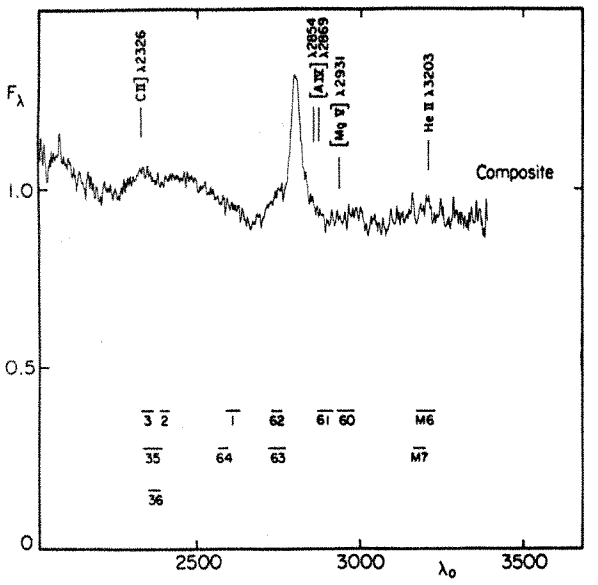
Real *Drosophila* genetics has shown that the eye colour mutant white/crimson (W^C) can frequently move its location. W. Gehring (Biozentrum, Basel) in looking for cloned heat shock genes has found a 'copia-like' element (P6F14) that localises to sites predicted by genetic mapping to contain the unstable W^C gene. The so-called 'copia' elements are a family of sequences present at around 30 sites on the chromosomes and which apparently can insert into new sites analogously to the better-known bacterial transposons. The significance of this work is that the dispersed and unstable copia DNA element has picked up a phenotype — in this case the white/crimson. Gehring indicated that in certain stocks the W^C gene may be left in a new location while the unstable element acquires a new phenotype.

M. Ptashne (Harvard University) has used genetic manipulation to mix up the control sequences and proteins of the *lac* genes and the lambda repressor and *cro* gene products. Coupled with DNase protection (footprinting) experiments using the lambda repressor and *cro* gene product he derives an elegant explanation of the role of the three tandem binding sites at the O_R region. There are at least four lessons from this work: (1) 'completely' different proteins can bind to the same DNA sequence; (2) the same protein can be both a positive and negative transcriptional regulator; (3) cooperative interaction between proteins determines transcriptional control and prophage induction is achieved by *rec*A mediated abolition of cooperativity; (4) all temperate phages have three binding sites governing the lytic/lysogenic choice; this arrangement probably prevents frequent mutation to virulence. There is no doubt that the O_R system is the best defined example of the control of transcription. In this case the difference of one base pair in the size of the spacer between the sites is thought to determine the direction of transcription. A. Landy (Brown University) has also used the footprinting technique and genetic engineering to show that the phage λ integration (*int*) gene product interacts with 240 base pairs spanning the core *att* site (at which λ integrates). This promises to explain the mechanism of at least one kind of site-specific recombination. It was left to F. Stahl (University of Oregon, Eugene) in summarising the meeting to make sure that participants obtained a working knowledge of the role of bacterial *chi* sequences in generalised recombination. The implication is that soon bacterial recombination and transcription will be fully explained in terms of known proteins interacting with characterised DNA sequences, leaving the many mysteries of eukaryotes to keep us amused.

Fe II emission lines in astronomy

from Correspondents

IN October the European Space Agency (ESA) sponsored a workshop on the subject of Fe II emission lines in stars and galaxies held at its Villafranca Satellite Tracking Station near Madrid, Spain — also known as VILSPA. It is from this station that ESA carries out its part in the operations of the International Ultraviolet Explorer (IUE) satellite (see *Nature* **275**, 5 October; 1979) which can observe the resonance lines of ionised iron in astronomical objects without high redshifts. Before IUE, many objects showing optical emission lines of this ion were known and with the early IUE data came the chance to check theoretical models for the emission from this complex ion by studying the key resonance lines.



Emission lines of ionised iron are widespread in astronomical objects and come from the Sun, all cool stars, some hot stars (in particular those with emission lines, those that are superluminous, the so-called symbiotic stars and binaries), eruptive objects like novae, supernovae, occasional very dense nebulae and extragalactic objects such as quasars and the related Type 1 Seyfert galaxies. In the case of galactic objects these emissions are known to arise in the cool parts of extended envelopes around stars. Typical electron densities and temperature run in the ranges 10^5–10^{11} cm^{-3} and 8,000–10,000 K. Where the densities are less than about 10^8 cm^{-3}, forbidden [FeII] emission is expected but J.-P. Swings (Liege) stressed that deducing the density from the ratio of forbidden-to-permitted lines may not always be justified since the lines' profiles may differ sharply between forbidden and permitted lines. Generally the lines that are seen in the optical and ultraviolet emanate from the odd levels around 5 eV, however M. Penston (VILSPA) and M. Snijders (University College London) reported the presence of several strong ultraviolet lines from even 10 eV levels in the slow nova RR Tel and in Nova Cygni 1978 respectively. Both Swings and R. Viotti (Frascati) noted the complex behaviour of the lines, with the relative importance of absorption and emission varying greatly between multiplets and between lines in the same multiplet. M. Friedjung (Paris) reported on the success of curve-of-growth type methods of analysing the Fe II emission spectra of several sources. It was generally agreed that the early investigations of the Fe II emission spectrum in galactic objects had lacked the quantitative dimension now available in the ultraviolet and regularly provided in the optical by modern observing methods: some new spectrophotometry was thought to be important.

Among extragalactic objects Fe II emission is seen in quasars and the related Seyfert type 1 galaxies. The same multiplets are strong in galactic sources and are identified in the optical region while [Fe II] may be marginally present in one case, IZW1, which has very strong Fe II. There is a great variation in the strength of Fe II relative to other lines or to the continuum. Of the Fe II multiplets, 42 may vary in strength with respect to the others from object to object. One of the most exciting results of the workshop was the convergence of many sets of data finding the same low contrast emission features between 2,000 and 3,000 Å. Both ground-based data on quasars with moderate redshifts by M. Phillips (Cerro Tolodo) and H. Netzer (Tel Aviv) and IUE data on low redshift Seyfert galaxies by Snijders and J. Clavel (VILSPA) agreed on the widespread existence of the features illustrated in the Figure. There was however some discussion of the identification of these features: although Fe II may be responsible, other explanations are not yet completely excluded and more work on this point will be done. Generally the intensity of these ultraviolet Fe II features is about equal to that of the optical Fe II lines in spite of factor 100-1000 differences in branching ratios. In addition the IUE observations of Seyfert galaxies with strong optical Fe II may show the presence of some features which could be ultraviolet multiplets in the wavelength range 1600-2000 Å (not previously seen in quasars) and a possibly anomalously strong Si III] to C III] ratio, which would indicate a high density.

Theoretical discussion centred on the Fe II lines in quasars and active galaxies and turned on the energetics. It was agreed that energy can be deposited in the neutral hydrogen, ionised iron region by photoionisation or collisional ionisation. Netzer presented models using a 'mean escape probability' method to handle the radiation transfer which showed that photoionisation by the X-ray continua of active objects could deposit adequate energy in these regions to create the observed Fe II and Mg II lines. Similar calculations by S. Collin-Souffrin and M. Joly (Paris) with a more detailed treatment of the radiation transfer also considered the effects of collisional ionisation. In spite of the difference in fundamental energy source, there was a general similarity in the emergent spectrum which can fit the observed intensity ratios of Mg II to Fe II and of Fe II (ultraviolet) to Fe II (optical). It was also agreed that the excitation mechanism was collisional and not from the resonance fluorescence process. The main argument against the latter is that observations at the Lyman limit in high redshift quasars suggest only a covering

An example of the data presented at the workshop which converged in showing substantial evidence for repeatable low-contrast features in the spectra of quasars and Seyfert galaxies between emitted wavelengths of 2000 and 3000 Å. (after Wills, Netzer, Uomoto and Wills)

factor of 5% or less by the emission line region: this proportion of the continuum absorbed by the Fe II ultraviolet resonance lines would be insufficient to explain the optical emissions. It was felt that the models, while capable of predicting the total intensity of the Fe II lines or the ratio of optical to ultraviolet lines, could not yet be used to predict ratios of individual multiplets because of the inaccuracy of the atomic physics data. Thus for example problems like the variable ratio of multiplet 42 (sextet) to other optical (quartet) multiplets, although explained qualitatively by C. Jordan (Oxford), could not yet be tackled quantitatively. As for the resolution of the fundamental choice of photoionisation and collisional ionisation of the Fe II region, it was agreed that the hydrogen lines offered the best diagnostic. There was as a result some discussion led by G. Ferland (Cambridge) of the anomaly seen in quasars and active galaxies where the hydrogen Lyman line is too weak relative to the Balmer lines by a factor of ten compared with radiative recombination.

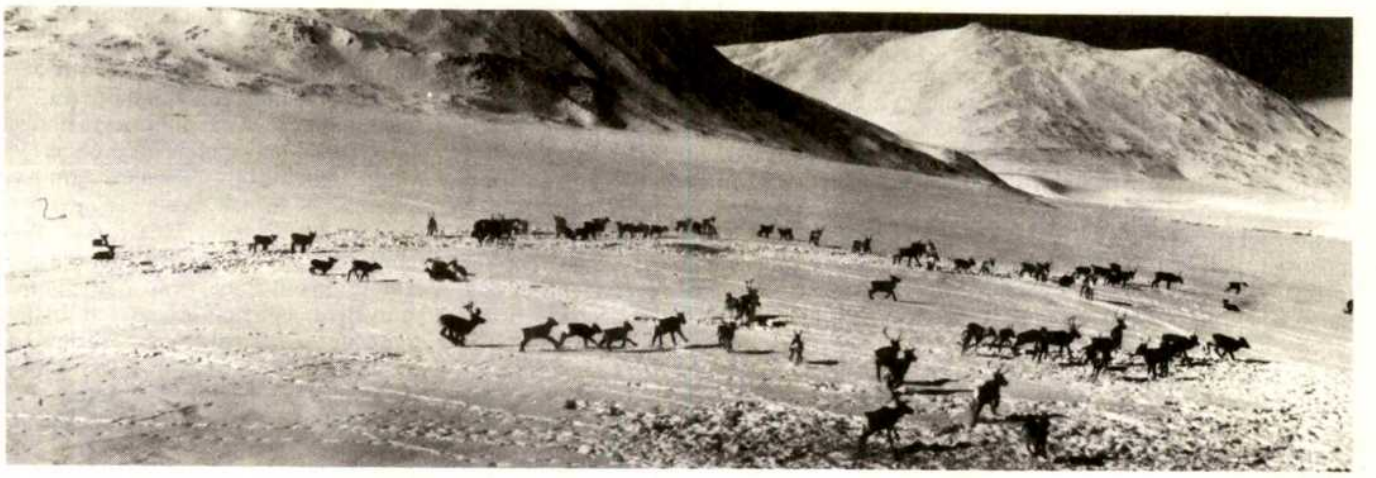
Because of the interlocking between ultraviolet and optical region transitions, it emerged that the line formation process is complex and that atomic data for many transitions are required. The physical processes of interest include collisional excitation, photo-excitation by strong ultraviolet lines, line self-absorption and recombination. Until now oscillator strengths have been calculated using simple approximations (for example, using the Thomas-Fermi potential) and with a limited number of configurations. Comparison with the available experimental data indicate that the calculated values are reliable only for the stronger lines if l-s coupling is valid; however spin-forbidden and two electron transitions are particularly important for Fe II. There was therefore an urgent need for more sophisticated multi-configuration calculations also allowing for spin-orbit interaction and for further measurements particularly in the ultraviolet region. Collisional excitation cross sections are also required and the commonly used simple approximations are unlikely to be appropriate. Although for high precision the close-coupling approximation will be needed, M. Seaton (UCL) pointed out that the distorted-wave method will give results of sufficient accuracy to be useful, given the state of the observations, and analysis of extragalactic spectra demands only somewhat crude atomic data. A start on this work has been made by H. Nussbaumer (Zurich) and P. Storey (UCL), stimulated by the workshop and new extragalactic results. They used the close-coupling method and a two-configuration basis to obtain collision strengths among the lowest four terms. The workshop also noted that processes involved in the ionisation and recombination of Fe II merit closer examination. Lastly a good knowledge of the energy level structure is often taken for granted. Yet astrophysicists are entirely dependent on fundamental laboratory spectroscopy, such as the excellent work at Lund reported to the workshop by S. Johansson, to begin their studies. It was agreed that such fundamental work ought to continue because of its immediate applications in explaining the many remaining unidentified transitions in the Sun and stars and in the theoretical modelling of the atoms. □

Reindeer and caribou

from Eigil Reimers and David R. Klein

REINDEER and caribou (all species of *Rangifer tarandus*) occur wild and domesticated in the northern circumpolar countries, and have been introduced into the Southern Hemisphere on South Georgia. Reindeer and caribou live in a variety of different environments and the second international reindeer/caribou symposium* provided an opportunity for comparing the different characteristics of these environments and the problems they produce. The endemic reindeer of the Svalbard Archipelago (Spitzbergen) for example, have no natural predators to contend with, are free from harrassing insects and are not hunted; in Greenland predators are absent; in Scandinavia and North America reindeer and caribou are subject in varying degrees to all three of these factors which are important limiting factors on population.

The wide population fluctuations that have occurred in wild reindeer and caribou populations and specific population regulation mechanisms can be considered from two main viewpoints. One considers hunting and predation as the main cause of population fluctuation, with overharvest by the two leading to population decline. Hunters and predators would as a consequence either be reduced in numbers or be forced to explore other sources of food, allowing the population to increase again.



The other viewpoint focuses on the range resources and the 'predation' on them by the reindeer and caribou. As the population increases, the range plant biomass will decrease, leading to poor physical condition of the animals, higher mortality and lower reproduction rates, eventually leading to population decline. With a small population the vegetation will recover and the population increase again.

In Svalbard, Scandinavia and Greenland the latter viewpoint is probably the more correct. For example, the recent decline in wild reindeer in Greenland is certainly associated with poor nutrition, caused by overgrazed ranges combined with a heavy load of parasites and disease. The situation there has been worsened through the introduction of parasitic skin warble and nasal bot flies in the 1950s when domestic reindeer were introduced.

Reindeer can use a wide variety of food species. Whereas lichens are the primary winter food base for reindeer and caribou on continental ranges, in the High Arctic mosses are important, as well as vascular plants which are of minimal importance further south. To understand animal range relationships properly considerable attention is now being given to assessing activity budgets. These, and especially feeding activity, reflect the balance between food intake and energy expenditure and therefore indicate the condition of the animals as well as that of the range. In this context Svalbard reindeer

*The 2nd International Reindeer/Caribou Symposium was held in Røros, Norway on 17-21 September, 1979. The proceedings will be published in 1980 by the Norwegian organising committee (Second International Reindeer/Caribou Symposium, Institute of Zoophysiology, University of Oslo, PO Box 1051, Blindern, Oslo 3, Norway). The proceedings will include a special section on the present status of *Rangifer* populations throughout the world. The third symposium is scheduled for Finland in 1982.

Caribou in the Canadian North

are receiving special attention because of apparent physiological adaptations to their especially extreme environment so far north. They accumulate large quantities of fat, they feed heavily on mosses which are avoided elsewhere and conserve energy through reduced activity especially in summer. In spite of the lower plant biomass and annual net primary production in Svalbard compared with areas further south, Svalbard reindeer have a greater population density and faster growth rates. Techniques now in use in studies of reindeer ecology run from remote satellite and aircraft sensing to map range and snowcover as well as to assess range quality, to radionucleotide tracer methods used to establish body nitrogen turnover and to estimate energy flow through the lichen-caribou-wolf chain throughout the year. Assuming that the wolves take a constant number of caribou throughout the year, the wolf harvest of caribou was estimated to be 30 ± 5 animals per wolf each year.

Serological techniques for assessing genetic differences and similarities among reindeer and caribou are contributing to the clarification of relationships between the circumpolar racial groups. The Svalbard reindeer are quite unrelated to the reindeer of the Scandinavian peninsula and comparisons with the Peary caribou of the Canadian Arctic have been initiated as an outcome of the symposium.

Man-made obstructions and harrassments such as aircraft, pipelines, highways, railroads and powerlines have pronounced effects on the movement, feeding activity and hence energy budgets of reindeer and caribou herds, and the disruption involved in building and servicing oil pipelines for example, with the associated traffic and helicopters, leads to alarm and avoidance reactions especially amongst females accompanied by young. Another unexpected and undesirable side-effect of man's activities has been seen in Sweden and Finland where the fertilisers used in the forestry industry seem to inhibit the winter foraging for lichens through the snow in these areas, apparently as a result of odours released by the ammonium nitrate and urea fertilisers. □

The neutron half-life and cosmology

from R.J. Tayler

THE recent announcement by Bondarenko *et al.* (*Sov. Phys. JETP Lett.* **38**, 303; 1978) of a new measurement of the neutron half-life giving a value of 10.13 minutes instead of 10.61 minutes, serves as a reminder that this value is of fundamental cosmological importance. A further measurement of the half-life has recently been made at Harwell and a preliminary analysis of the results suggests that the value obtained will also be less than 10.6 minutes (J. Byrne, private communication).

Since the discovery of the microwave background radiation in 1965 there has been a general hope that the hot big bang cosmological theory, originally proposed by Gamow, provides a good first approximation to a description of the evolution of the Universe. One of the key predictions of this theory is the chemical composition of the Universe after the first few minutes. This should be about three parts hydrogen to one part helium by mass, with a very small admixture of deuterium, ^{3}He and ^{7}Li. The precise division between hydrogen and helium and the other light isotopes depends on how rapidly the Universe expands in its early stages and on the relative number of protons and neutrons at the time that nuclear reactions converting hydrogen into helium become effective. The simplest version of the big bang theory has one free parameter which can be related to the present mean density of the Universe (ϱ). The lower the value of ϱ_0, the lower also was the helium production in the early Universe. There is an uncertainty of about two orders of magnitude in ϱ_0 and this corresponds to a helium production of between 0.23 and 0.27 by mass.

The rate of expansion of the Universe is increased if there are more stable elementary particles than is at present believed. In the very early Universe all particles and their antiparticles are expected to be present in equilibrium with the radiation field and stable massless or low mass particles survive through the period of nucleosynthesis and influence the expansion of the Universe. If, as seems very likely, a third neutrino, the tau neutrino, exists, the predicted helium production is increased to the approximate range 0.25 to 0.29. At present there is no unanimity amongst elementary particle physicists about the number of leptons and associated neutrinos, but if there are more than three sets a further increase in helium production is implied.

The half-life of the neutron enters into the problem because it affects all the reactions which convert neutrons into protons. If the half-life is reduced, neutrons are more readily converted into protons and the helium production is reduced. When Gamow first proposed his theory, the half-life was believed to be 14 minutes. By 1965, when the first very serious comparisons between theory and observation were made, the value 11.7 minutes was used and the probable helium production fell in the range 0.25 to 0.29. This was reduced to the 0.23 to 0.27 quoted above, when the accepted value of the half life became 10.6 minutes. A further reduction to 10.1 minutes would give the values 0.22 to 0.26, or 0.24 to 0.28 if the tau neutrino is included.

When the predictions of the theory are compared with all relevant observations, including those of element abundances and those bearing on the value of ϱ_0, it seems just possible that the simplest version of the theory is compatible with observation. Most observed helium abundances are greater than 0.23, although considerably lower values have been observed in the solar wind. It is usually believed that this results from selective loss of elements by the Sun, although Isaak (*Nature*, in the press) has recently claimed that observed solar oscillations and a low neutrino flux demand a low helium content. If we dis-

©1979 Macmillan Journals Ltd

regard this rather controversial point, the tightest observational constraint on the theory is given by the deuterium abundance, which although very small depends very strongly on the rate of expansion of the Universe.

This agreement between the simplest theory and observation would probably be removed if even a fourth or more species of neutrino were discovered; *inter alia* the predicted helium abundance would be too large. There are more complicated versions of the theory which involve the Universe's being filled with degenerate neutrinos or antineutrinos, which might fit the observations, but these seem rather unattractive. A reduction in the neutron half-life of the amount found by Bondarenko *et al.* would make a small correction in the opposite direction. However, the main significance of the result for cosmologists is to remind us that the predictions of the hot big bang theory are not secure until the neutron half-life is really well known. A definite result that it could not be less than 9.5 minutes (say) would be extremely helpful. □

Amorphous semiconductors

from S.R. Elliott

THE dominant theme at a recent conference on amorphous and liquid semiconductors*, was the hydrogenated amorphous silicon (a-Si:H) system. This is perhaps not too surprising in view of its possibilities as a device material, for example in solar cells (see *News and Views* **275**, 93; 1978; **277**, 85; 1979). Many of the papers on a-Si:H dealt with aspects of material preparation (for example glow-discharge decomposition of SiH_4 or sputtering in Ar/H_2 atmospheres) or characterisation, such as the measurement of H content by thermal exodiffusion or infrared spectroscopy, and investigations of gap-state density by various field-effect or capacitance-voltage measurements. Few structural studies were reported, although R. Mosseri *et al.* (CNRS, Meudon) compared X-ray diffraction data on a-Si and a-Si:H, and D. Weaire *et al.* (Heriot-Watt University) discussed a hand-built 'ball-and-stick' structural model for a-Si:H containing about 20 at.%H. An entire session was devoted to photovoltaics and solar cell devices, discussed by workers from RCA, Exxon, Dundee and Osaka, and I. Shimizu *et al.* (Tokyo Institute of Technology) described how a-Si:H films could also act successfully as electrophotographic sensors in a manner similar to another amorphous material, selenium, used in copying machines.

A. Madan and S.R. Ovshinsky (Energy Conversion Devices) reported on fluorinated silicon, a-Si:F:H, (made by the glow-discharge decomposition of SiF_4/H_2 mixtures) which, they claimed, has a lower density of gap states than solely hydrogenated material and which therefore should lend itself to more efficient doping (see also *Nature* **276**, 482; 1978). Indeed, for material containing about 5 at. % F, doping with AsH_3 or PH_3 in the gas phase produced material having, at the highest doping levels, conductivities some three orders of magnitude higher than comparable hydrogenated material, although p-type doping with B_2H_6 was found to be comparable in both cases. With a band-gap some 10% larger (rather more suited to absorption of the solar spectrum), a-Si:F:H looks as if it might have considerable device potential. J. Knights (Xerox) presented an interesting paper on growth and morphology of a-Si:H, in which strong evidence from nuclear magnetic resonance, electron microscopy and other techniques was presented for the inhomogeneous incorporation of H. Previously, it had generally been believed that H was uniformly distributed throughout the bulk; Knights, however, showed that high H-containing samples were formed from clusters about 100 Å in diameter, with the H concentrated at the cluster boundaries in the form of SiH_2 configurations. Lower H-containing samples did not show this island morphology, but appeared homogeneous. Plasma chemistry seems to play a major part in the deposition process, as might be expected.

Chalcogenide glasses, the other main area of amorphous semiconductor research, also received much attention. The major breakthrough in this field in the past two or three years has been the realisation that intrinsic structural defects have a major role in determining many electronic properties of these materials. These point defects — dangling bonds — are believed to undergo reconstructions in which electron pairing at these sites occurs. Thus, considering a-Se as an example (in which normally bonded atoms are 2-fold coordinated, forming chains), a simple dangling bond is 1-fold coordinated and contains one electron in the orbital formerly used in bonding. Reconstruction occurs by the transfer of an electron between two such defects: addition of the electron to a centre results in a negatively charged 1-fold coordinated centre: removal of an electron results in an empty orbital capable of forming a dative bond with the full lone-pair orbital on a neighbouring Se chain, thereby forming a positively charged 3-fold coordinated centre. J. Joannopoulos (Massachusetts Institute of Technology) described some of the first self-consistent calculations on such defect configurations in an attempt to obtain total energies. However, it seems that, at least at present, the inability to model the atomic relaxations in a realistic manner leads to estimates accurate only perhaps to 0.5 eV, unfortunately not precise enough to determine the relative stability of various configurations.

B. Golding (Bell Laboratories) described some fascinating experiments probing low-lying excitations — so-called two-level systems — which seem to exist in chalcogenide glasses. These had been thought to be due to the tunnelling of atomic groups between two nearly equivalent configurations, and they dominate the thermal properties below 1 K. Stimulated emission (in the form of ultrasonic or electromagnetic echo radiation) from these two-level systems can be obtained, and it was shown that such electrical echoes could be altered in magnitude by annealing or by irradiation with light having the energy of the band-gap (or half-band-gap) of the material. The importance of this result lies in the fact that these changes are precisely in the same sense as those observed in photo-luminescence or electron spin resonance under the same conditions, properties which are believed to be due to the structural defects mentioned earlier. This is the first direct indication that a connection may exist between two-level systems and structural defects in chalcogenide glasses, an intriguing possibility.

G. Pfister (Xerox) reported on the incorporation of additives (such as transition and alkali metals) in chalcogenide glasses and the effect on properties such as drift mobility and photoluminescence. The discovery that, although the former is dramatically affected, the latter is relatively unaffected by doping means that the simple model for defects in chalcogenide glasses needs to be modified. On a more technological note, a novel method of high resolution image replication using amorphous Ge–Se films was described by K. Chopra *et al.* (Indian Institute of Technology, Delhi). This technique relies on the enormous thickness changes (about 12%) that occur when obliquely deposited films are illuminated with band-gap light; this method has the advantage of being conducted under dry conditions, unlike conventional photolithography.

Finally, the prize for the most unusual and esoteric method of glass production must surely go to a joint Czech and Russian group (L. Stourac *et al.* Czech Academy of Sciences, Prague & Institute of Space Research, Moscow). The experimental environment they used was the weightless condition aboard the Salyut 6 spacecraft, and glass formation and the influence of zero gravity on the structure and opto-electronic properties of Ge-Sb-S glasses were studied. I fear that it will be a little time yet before British researchers have an opportunity to conduct similar experiments! □

*The Eighth International Conference on Amorphous and Liquid Semiconductors was held on 27-31 August, at Harvard University. The Proceedings are being published as a separate volume of the *Journal of Non-crystalline Solids*.

Flux variations of QSO 0957+561 A, B and image splitting by stars near the light path

K. Chang & S. Refsdal
Hamburger Sternwarte, Gojenbergsweg 112, D-2050 Hamburg 80, FRG

If the double QSO 0957+561 A, B is the result of gravitational lens actions by a massive galaxy, stars in its outer parts and close to the light paths may cause significant flux changes in one year. One star can split a QSO image into two to four images with angular separations of $\sim 10^{-5}$ *arc s.*

RECENT observations[1-3] of the double QSO, 0957+561 A, B (redshift $z = 1.405$, angular separation $\alpha = 5.7$ arc s, mag ≈ 17) strongly indicate that a large and compact mass (galaxy) lies close to the line of sight between Earth and the QSO. The massive galaxy thereby acts as a gravitational lens. The theory for the case of a point mass (or a compact spherically symmetrical mass distribution) has been presented elsewhere[4-8,14]. The most convincing proof of a lens effect would be the demonstration of a time delay (of months or years) between flux fluctuations in the two QSOs, which would occur by intrinsic fluctuations in the QSO, as the light travel time is different along the two light paths[5,6,9,10,14].

For source diameter <1 lt yr we show here that flux fluctuations (time scale of months and more) can also be caused by stars, in the outer parts of the deflecting galaxy, moving close to one of the light paths. Such flux fluctuations in the two images would certainly be uncorrelated and show no time delay effect. The absence of a time delay effect should therefore not automatically be taken as disproving the lens effect. The observed light curves would probably show variations due to intrinsic variations in the QSO as well as the influence from the above-mentioned stars. The presence of a time-delayed component in the observed fluctuations would, however, not be difficult to demonstrate.

To simplify the discussion, we consider here the effect of only one star at a time, which is sufficient to demonstrate the importance of stars close to the light path. We shall see that an interesting aspect of the problem is the splitting of each image into a close group of images with angular separation of $\sim 10^{-5}$ arc s. Even one star alone can cause a QSO-image to split into two to four images. Of particular interest is the transition (due to proper motions) from four to two images (or the opposite). Before such a transition occurs, two of the four images are seen to move towards each other, get brighter, and then merge and disappear. The time scale for the disappearance of the two images will roughly be the time for the QSO to move transversely its own diameter D and can be estimated to be about $600 D\, c^{-1}$ in the present case. For D values of <0.1 lt yr, flux variations of 50% and more can occur and even for D values of ~0.5 lt yr a variation of 5% during 30 yr is possible. For such large D values, however, the different images discussed above will usually merge into one image. From the light curves of the double QSO it should be possible to get information on the size and structure of the QSO as well as on the mass distribution in the outer parts of the deflecting galaxy.

Gravitational lens geometry

The geometry of our problem is indicated in Fig. 1. The heavy solid line represents a light ray coming from Q which is deflected (by the galaxy (G) and the star (S)) when crossing the deflector plane at the point (ξ, η) and which finally crosses the observer's plane at the point (x, y). The affine parameters, L and λ, are convenient distance parameters for gravitational lens problems at cosmological distances[11,12]. One might at first think that the Einstein-deflection arising from the nearest star can be neglected since it is only $\sim 10^{-6}$ times the galaxy deflection

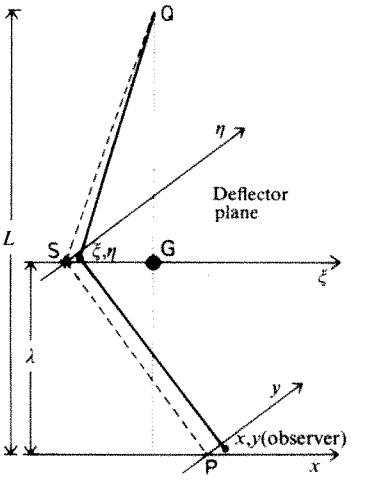

Fig. 1 Light source Q with the affine parameter L (ref. 11) large deflector G (galaxy) with the affine parameter λ and small deflecting mass S (star). The deflector plane (ξ, η) and the observer's plane (x, y) are normal to the line QG. For convenience we chose the origin of the (ξ, η) plane to be at S and the x axis to be parallel to the ξ-axis. The origin P in the (x, y) plane is obtained by considering a light ray QSP for which only the galactic deflection is taken into account. The solid line from Q through the points (ξ, η) and (x, y) represents the path a photon would take when the deflections from G and S are taken into account.

© 1979 Macmillan Journals Ltd

($M_G/M_S \approx 10^{12}$). For the observed fluxes in the observer's plane, however, it is not the values of the deflection angles which count, but rather their derivatives with respect to the deflector plane coordinates, and these derivatives turn out to be of the same order of magnitude.

Basic equations

A suitable form for the transformation of the (ξ, η) plane into the (x, y) plane for the light rays from a point source is the following:

$$x = \xi + \gamma\xi - \xi/(\xi^2 + \eta^2) \quad (1)$$

$$y = \eta - \gamma\eta - \eta/(\xi^2 + \eta^2) \quad (2)$$

The galaxy has here been treated as being symmetrical about QG and with negligible mass outside S. The deflection due to the galaxy is a function of ξ and η and is taken to be the deflection in $\xi = \eta = 0$ plus a term linear in ξ and η. Such a power expansion is a very good approximation since we shall only be interested in light rays which pass S at distances ≤ 1 lt yr. The unit of distance

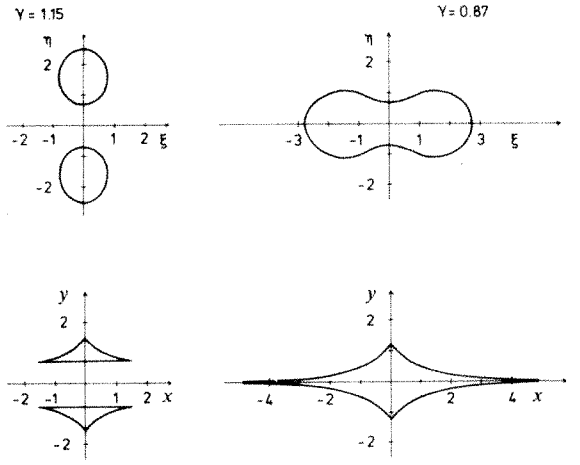

Fig. 2 Critical curves in the deflector plane (ξ, η) and in the observer's plane (x, y) for the cases $\gamma = 0.87$ and $\gamma = 1.15$.

in the (ξ, η) plane has been taken to be the radius r_0 of the luminous ring which would have been seen only if the star had been acting as a lens with the observer directly behind the star. The value of r_0 is[4,12] (normalised unit),

$$r_0 = \frac{2}{c}\left(GM_S \frac{\lambda(L-\lambda)}{L}\right)^{1/2} \quad (3)$$

For $M_S \approx 1\ M_\odot$ and for cosmological distances the value of r_0 is of the order of 0.1 lt yr. Finally, the normalised unit in the (x, y) plane is $r_0 L/(L-\lambda)$. An interesting feature of equations (1) and (2) is that there is only one free parameter γ and that the γ-terms arise from the galactic deflection.

If we neglect the effects of the deflecting star, we can drop the third term on the right-hand side in equations (1) and (2):

$$x = \xi + \gamma\xi \quad (1a)$$

$$y = \eta - \gamma\eta \quad (2a)$$

We denote the flux which would have been observed without any lens effect by F_0 and the corresponding flux if only the galactic deflection is taken into account by F_0'. It is then easily seen from geometrical optics that

$$F_0'/F_0 = |J|^{-1} \equiv \left|\frac{\partial(x, y)}{\partial(\xi, \eta)}\right|^{-1} = |1 - \gamma^2|^{-1} \quad (4)$$

where J is the jacobian determinant of the transformation. The flux ratio of the two observed images A and B of the QSO is $F_A/F_B \approx 4/3$ from the available radio observations[2]. Using the conventional lens effect analysis[4] (galaxy only) one finds furthermore

$$F_A - F_B = F_0 \quad (5)$$

so that

$$F_A = 4F_0,\ F_B = 3F_0 \quad (6)$$

We then get an approximate estimate of γ by inserting F_A and F_B instead of F_0' in equation (4):

$$\gamma_A \approx (1 - F_0/F_A)^{1/2} \approx 0.87 \quad (7)$$

$$\gamma_B \approx (1 + F_0/F_B)^{1/2} \approx 1.15 \quad (8)$$

Equation (4) does in fact allow four solutions of γ for a given flux ratio. It is, however, easy to see that γ must be positive when $M_G > 0$. We also know that the bundle corresponding to the brightest image A has not been through a caustic between source and observer whereas 'bundle B' has been through a caustic. From this it follows that $\gamma_A < 1$ and that $\gamma_B > 1$ and the values given in equations (7) and (8) then follow as the only possible values of γ_A and γ_B.

Critical curves and number of images

An interesting property of equations (1) and (2) is that the inversion of these equations leads to fourth order equations in ξ and η and that one can have two to four solutions for a given x, y. This means that up to four different light rays passing close to S can reach the same point in the observer's plane, so that the observer will see a group of 2–4 images (angular separation $\sim 10^{-5}$ arc s).

To find out how the number of solutions depends on the observer's position (x, y), the location of the points for which the jacobian of x and y in equations (1) and (2) is zero turns out to be very important:

$$J(\xi, \eta) = \frac{\partial(x, y)}{\partial(\xi, \eta)} = 0 \quad (9)$$

Equation (9) defines the 'critical curves' in the (ξ, η) plane. The transformation of these curves into the observer's plane by equations (1) and (2) then defines the critical curves in the (x, y)

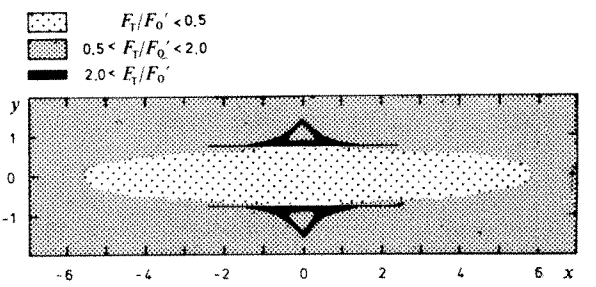

Fig. 3 The observer plane, for the case $\gamma = 1.15$, divided into a high flux region, an intermediate flux region and a low flux region. F_0' is the flux which would have been observed, if only the galactic deflection is taken into account (the star is neglected).

plane. The critical curves in the (ξ, η) plane are found to be Cassini ovals and they are plotted for the cases $\gamma = 0.87$ and $\gamma = 1.15$ in Fig. 2 together with the corresponding critical curves in the (x, y) plane. These two cases also demonstrate the two types of critical curves one can obtain. For $\gamma < 1$ one closed curve is always found in each plane; for $\gamma > 1$, however, there are always two closed curves.

By using topological arguments one can show that the number of images of a point source seen by an observer can only change when he crosses a critical line, and that the number of images then changes by two. This is also in perfect agreement with our numerical experience; we always find that the observer sees two images when he is outside the critical curve(s) and four solutions when he is inside one of the critical curves.

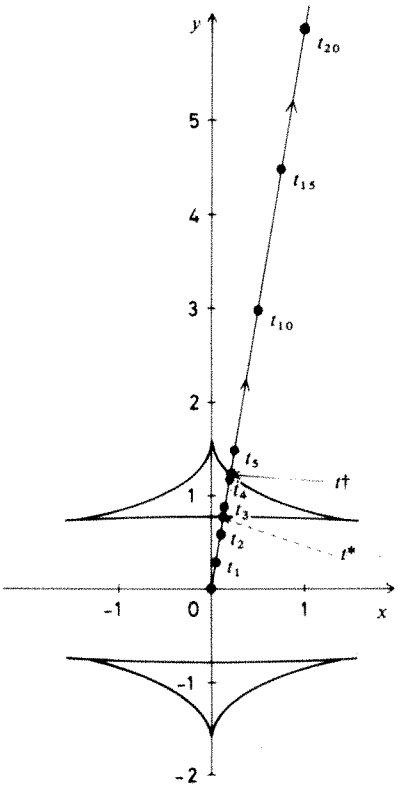

Fig. 4 Motion of the observer in the (x, y) plane ($\gamma = 1.15$) for the case discussed as an example in the present investigation. The direction of the observer's motion is indicated by an arrow.

Flux values

Since the images discussed above will have very small angular separations ($\approx 10^{-5}$ arc s) we shall mainly be interested in the total observed flux F_T from all the images

$$F_T = \sum_{i=1}^{N} F_i, \qquad N \leqq 4 \tag{10}$$

Here F_i is the observed flux from image i. In analogy with equation (4), but now using equations (1) and (2) instead of equations (1a) and (2a) one gets for a point source

$$F_i = J^{-1}(\xi_i, \eta_i) F_0 \tag{11}$$

As the light rays from B pass closer to the galaxy (that is pass through a denser star field) than those from A, the chance of getting a large disturbing effect from a star should be greater for B than for A. We therefore concentrate on B ($\gamma = 1.15$).

Figure 3 shows the main features of the function $F_T(x, y)/F_0'$. We see that a high flux region (star causes more than +100%) is found on and close to the critical curves, whereas a low flux region (star causes a reduction of 50% or more) is found in an extended region around the x-axis. The high F_T-values close to the critical curve ($J = 0$) were, of course, to be expected, since a vanishing of the jacobian for at least one of the images means an infinite flux (within the point source and geometrical optics approximation). For sources which are small but finite, one can show that the maximum value of F_T which occurs when an observer passes a critical line is proportional to $D^{-1/2}$, where D is the diameter of the source. Note that the same type of dependence was found for the spikes discussed by Benson and Cooke[13]. The large low flux region obtained in the present calculation does not occur in the case of a single point mass lens ($\gamma = 0$) discussed extensively elsewhere[4,7]. Observers within 0.75 distance units from the origin would even find that the flux is reduced by more than 90%. This is in striking contrast to the single point mass case as then a high flux region is found close to the origin. The region with 100% increase or more reaches for instance 0.55 distance units out from the origin in the (x, y) plane.

Motion in the observer's plane

Rough estimates of the transverse velocities (normal to QG) of Q, S (ref. 2) and the observer lead to an observer's velocity relative to P ($x = 0$, $y = 0$) of about 1,000 km s^{-1}. The unit of distance in the observer's plane which was chosen to be $r_0 \cdot L/(L - \lambda)$ depends on the redshifts, the Hubble parameter H_0 and slightly on the cosmological model. For galaxy redshifts

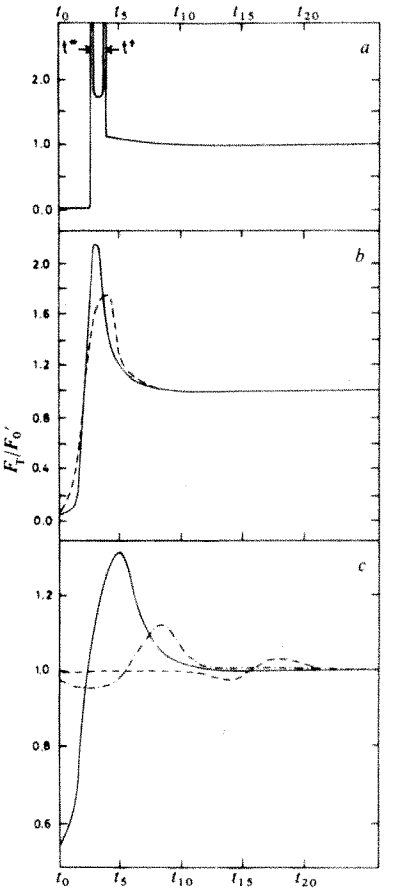

Fig. 5 Light curves with different values of D'. The real diameter of the source object Q is given by $D' r_0 L/\lambda$. *a*, Point source; *b*, $D' = 0.5$, – – – $D' = 1.0$; *c*, — $D' = 2.0$, –·– $D' = 4.0$, – – – $D' = 10.0$.

$z_G \approx 0.5$ and $H_0 = 60$ km s^{-1} Mpc^{-1} we find approximately

$$r_0 \cdot L/(L-\lambda) = 0.1 \text{ lt yr} \quad (12)$$

a value which we shall now adopt. A motion amounting to one distance unit in the observer's plane (relative motion between observer and P) will then take with velocity 1,000 km s^{-1} about

$$\Delta t = 30 \text{ yr} \quad (13)$$

An example of a motion in the observer's plane is shown in Fig. 4. Starting at time $t = t_0$ at the origin, the motion at constant velocity is followed through times $t_1 = t_0 + 0.3\,\Delta t$, $t_2 = t_0 + 0.6\,\Delta t$ till $t_{20} = t_0 + 6\,\Delta t$.

Point source

The change in the total flux F_T is demonstrated in Fig. 5*a* for the case of a point source. It is seen that $F_T(t)/F'_0$ starts out as being very small and stays <0.1 until the critical curve is reached at time $t = t^*$. Then an abrupt rise to very high values occurs (infinite by geometrical optics approximation). Very close to a critical curve (on the inside) the value of F_T/F'_0 is proportional to $d^{-1/2}$, the constant of proportionality being ~ 1 if the distance d to the critical line is expressed in normalised units. Therefore one has a minimum in F_T before the next crossing of the critical curve at $t = t\dagger$, then one again finds very high F_T values. An abrupt reduction to values $F_T/F'_0 \approx 1.2$ outside the critical curve follows. The positions of the different images in the (ξ, η) plane (on the sky) is demonstrated in Fig. 6. Starting with two images on the ξ axis one can see that a 'new' very bright image appears at $t = t^*$ and that this image immediately splits into two images. One of these images then merges with one of the original images at $t = t\dagger$ and the joint image disappears.

Extended sources

We now consider circular sources without limb darkening and with various diameters D. The source centre is in Q and the observer motion is the same as for the point mass case. The time dependence of F_T/F'_0 is shown in Fig. 5*b* and *c* for various values of D'. D' is the diameter of the source transformed into the observer's plane (just as the point source is transformed into point P) in normalised units. It is then easily seen that the diameter of the source is

$$D = D' r_0 L \lambda^{-1} \approx 0.05 D' \quad \text{lt yr} \quad (14)$$

We have used $H_0 = 60$ km s^{-1} Mpc^{-1} and $M = 1 M_\odot$. For the most reasonable cosmological models ($0 < q_0 < 1$) and redshifts z_G ($0.3 < z_G < 1$) equation (14) is accurate to ±40%.

As expected we find that the amplitudes of the flux variations get smaller and the time scales larger when D' increases. By the largest D' value shown in Fig. 5 ($D' = 10$) we still see, however, that a 5% increase in ~30 yr is possible. If we consider flux variations of <1% as insignificant we find that significant flux variations can only occur for $D' < D'_{crit} = 20$. From equation (14) we see that this corresponds to

$$D < D_{crit} = 1 \quad \text{lt yr} \quad (15)$$

Stars as deflectors can therefore only give significant flux changes for D smaller than about 1 lt yr.

As for the position and appearance of the extended images, we note that a large increase in the flux of an image is always connected with a large deformation, and that the separate images which appear of a point source often smear together for large D' values.

For small D' values the rapid flux changes when the observer crosses a critical line is of utmost interest. We have found that the maximum value of F_T/F'_0 when crossing a critical line is usually about ($D' \lesssim 0.1$)

$$F_T/F'_0 \approx 2/\sqrt{D'} \quad (16)$$

The time scale for the disappearance or appearance of the bright images is

$$\delta t = D' \Delta t \quad (17)$$

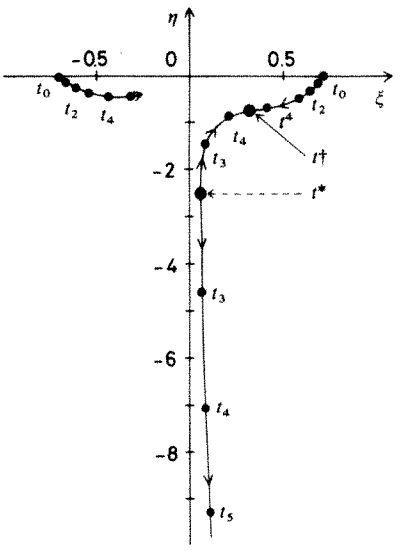

Fig. 6 Motion of the images in the deflector plane.

The very rapid X-ray fluctuations (we think intrinsic) of some quasars (time scale some hours), which have been reported from the Einstein satellite, do indicate that the D-value of the X-ray source is less than 5×10^{-4} lt yr; that is $D' < 0.01$. Large changes in F_T caused by the lens effect could then occur within some months.

Probability considerations

We have seen that significant changes in the total flux F_T can occur for sources less than about 1 lt yr, if a star happens to be close enough to the light path. The probability that such flux changes will actually occur depends on the number density of stars in the deflector plane. For simplicity we consider all stars to have one solar mass and to be lying in the deflector plane. One can then easily show that the average number density $\langle n \rangle$ of stars out to a distance GS from G is $\langle n \rangle = \pi^{-1}$ per normalised area (r_0^2). We have here made use of equation (3) for the whole galaxy, that is, with M_G instead of M_S. We can then write the number density of stars close to the light bundle as

$$n = \frac{1}{\pi} \frac{n}{\langle n \rangle} \quad (18)$$

The number density of projection points P in the observer's plane (per normalised area $r_0^2 L^2/(L-\lambda)^2$) is

$$n' = (F'_0/F_0) \cdot n = \frac{3}{\pi} \frac{n}{\langle n \rangle} \approx \frac{n}{\langle n \rangle} \quad (19)$$

as the lens effect of the galaxy reduces the projected area in the observer's plane with a factor F'_0/F_0. Noting that the low flux region in the observer's plane ($F_T < 0.5 F'_0$) has an area of 12 it is clear that the probability of large flux changes is significant even for $n/\langle n \rangle$ values as small as 0.01. We consider more likely values of $n/\langle n \rangle$ to be ~0.1. In that case the disturbance from several stars at a time would usually have to be considered.

We thank Drs J. Reed and R. Schröder for valuable discussions.

The heat flow field in mainland UK

S. W. Richardson & E. R. Oxburgh*

Department of Geology and Mineralogy, University of Oxford, Parks Road, Oxford, UK

Belts of relatively high flux correspond to zones of crust enriched in radioactive heat production to ~15 km depth. The enrichments were introduced into the crust by granitic magmas.

MOST of the ~80 measurements of heat flow in the mainland UK[1-5] have been made in vertical or near vertical holes between 200 and 500 m deep from which both thermal conductivity and equilibrium thermal gradient information have been obtained. Data available up to October 1977 are summarised elsewhere[1-5], since when 26 more values have been obtained.

Although the distribution of observations is much less uniform than desirable and is determined largely by the availability of suitable boreholes drilled by other bodies, it is clear that heat flow varies in a more or less systematic manner by as much as a factor of three, between different parts of the country. Figure 1 shows the distribution of observations, and contours for 45, 60 and 75 mW m^{-2}. The contours are drawn by hand on the basis of the observations shown, without reference to any additional constraints. There are clearly different, equally possible placings for the lines shown, but from most of these emerge the broad regional patterns. A zone of relatively high heat flow extends northwestwards across central and northern England and may continue into southern Scotland (probably terminating in the Scottish Midland Valley). A second, less well defined, belt runs from Cornwall in extreme south-west England eastwards along the south coast of the country. A relatively low heat flow area occupies the western English Midlands and much of central and north Wales. The few values of north of the Scottish Midland Valley are all rather low.

Although a much better distribution of observations is required to substantiate this pattern, the observation density makes this one of the most thoroughly studied areas of its size in the world, and patterns of heat flow variation on this scale have not previously been described.

The average heat flow for the whole country is close to 60 mW m^{-2} (see Fig. 1), the lowest value recorded being 25 mW m^{-2} and the highest 130 mW m^{-2}. The precise value for the mean depends on the method used to derive it, but clearly the country is on average not notably different from other stable continental areas[6-8]. The average heat flow is, for example, close to the European average[9], 64 mW m^{-2}, and in general the values found in the UK are between the low regional flux of Scandinavia and the higher flux of central and southern Europe.

Correlation of heat flow pattern with other features

Perhaps the most striking feature of Fig. 1 is the relatively poor correlation between the heat flow pattern and other regional geophysical features. Although not presented here, maps of bouguer gravity and aeromagnetic anomalies were prepared as overlays to the heat flow map; the former shows no obvious regional correlation at all, while there is a weak correlation between the trends of magnetic anomalies and the trends of the two belts of higher heat flow values.

There is similarly little correlation with the surface geology. A weakly folded cover of Mesozoic rocks conceals the detail of the folded Palaeozoic and Precambrian basement over much of England[10-12]. In south-west England the zone of higher heat flow corresponds approximately to the trend of the Hercynian Fold Belt characterised by folded slates cut by granitic intrusives; the heat flow contours appear to close eastwards as the belt is buried by the Mesozoic cover.

The northern England zone of higher heat flow apparently cuts across the sedimentary and tectonic features of the Upper Palaeozoic basement, and the Lower Palaeozoic is very poorly known except from isolated outcrops and boreholes. The zone does, however, correspond to the subsurface trend of a hypothetical belt of folded Lower Palaeozoic rocks recently proposed by Evans[13].

The ill-defined low heat flow area contained between the two higher zones, corresponds in its eastern part to a region believed to be largely underlain by Precambrian rocks but extends westwards into north and central Wales where folded Lower Palaeozoic rocks occur at the surface.

Compilations of continental heat flow show that there is a broad dependence of values on the age of the last thermal event to have affected the crust[7,14-17]. The majority of the values shown in Fig. 1 come from crust which is in this sense 400–250 Myr in age and exhibit no correlation with the age. The variation of heat flow reported here must thus represent the considerable scatter found in the broad-scale compilations.

Origin of the variation in surface heat flow

The fact that the mean heat flow for the country as a whole is not exceptional, together with the scale width of the variation in surface heat flow, suggest that the origin of the pattern is not to be found in some unusual condition in the mantle but rather reflects some crustal condition or process[18-20].

Even very slow and low-volume flows of water in the crust may transfer amounts of heat by convection which are of the same order as the vertical conductive flux[2,21]. Such flows must, however, be driven either by a topographic head, or by initial horizontal temperature differences. Viewing the regional heat flow pattern as a whole there is no obvious correlation with topography or with the known pattern of near surface groundwater movements[22]. On the other hand, there are almost certainly areas where water movements do control the heat flow on a local scale (for example, the limestone area of south Derbyshire[1]).

The thermal conductivity of rocks commonly varies by a factor of two between different lithologies[2,3]. A crust characterised by adjacent belts of high conductivity and low conductivity rocks would be expected to refract any uniform heat flux supplied to it from below, so that the higher conductivity regions carried a higher heat flow, at any rate near their margins[24,25]. We have considered the possibility that the high heat flow belts of Fig. 1 are formed in this way and simple two-dimensional analytical and numerical modelling has been carried out. We find that steep sided zones with twice the conductivity of their surroundings, and extending to a depth of half, or even the full thickness of the crust, show strong refractive edge effects which perturb the surface heat flow by $\sim \pm 20\%$. This would be just sufficient to explain the amplitude of the observed variation but the sharp depressions and elevations of heat flow at the junction of the conductivity domains do not match the observed broad areas of low flux and intervening belts with distinctly higher flux throughout. Despite these general considerations there is little doubt that on a local scale refraction of heat flow is important[26].

In regions which have not experienced recent igneous or metamorphic activity a significant fraction of the surface heat

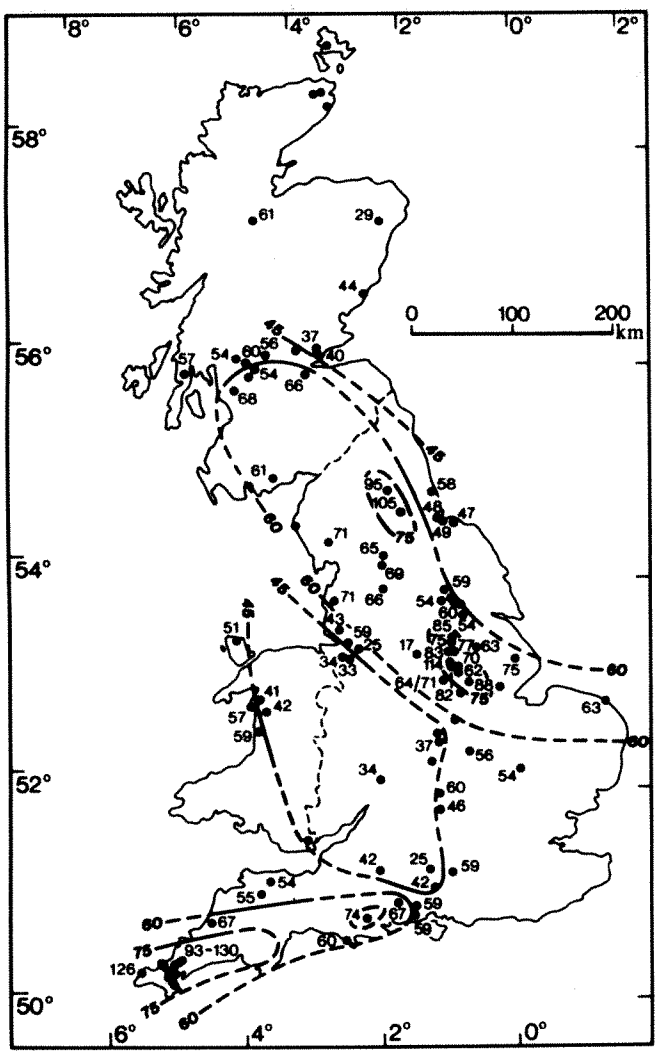

Fig. 1 Heat flow sites with the values contoured at 45, 60 and 75 mW m^{-2}. Although uncertainty attends the placing of the contours, particularly across the Scottish Southern Uplands and in Wales, the two belts of higher values stand distinctly above background.

flow of continents is derived from heat producing isotopes which are strongly concentrated in the continental crust with respect to mantle abundances. At equilibrium, the surface heat flow may be expressed as:

$$q_0 = q_m + \int_0^m A\,dz \qquad (1)$$

where m refers to the depth (z) above which enrichment is both significant and variable; q and A refer to heat flow and heat productivity respectively. Studies of several continental regions[27–29] suggest that the integral in equation (1) can be solved simply as A_0D on the empirical grounds that q_0 and the surface heat production are linearly correlated in regions where high grade gneissic, or granitic intrusive rocks outcrop. The parameter D in these terrains has a characteristic value of 8.0 ± 1.5 km and q_m accounts for about half the average heat flow observed[29]. We have previously reported heat flow and productivity measurements for southern Britain[1] which showed good correlation where either granitic or low grade cleaved metasediment or metavolcanic rock outcrop, or are encountered as basement in boreholes. These and further data for Britain, including southern Scotland, are plotted in Fig. 2 which support the correlation ($R = 0.96$); D has a value of 16.6 km. This relationship implies that the granitic and weakly metamorphic basement of Britain, whether outcropping at the surface or buried beneath a platform of younger sediment, is enriched in heat production to depths of ~15 km and that the degree of enrichment is geographically variable and causes the heat flow variation.

Although, in principle, such an explanation could account for the large scale features of Fig. 1, it does not explain how such variation in heat production could have come about. We have argued elsewhere[1] that much of the basement to these depths comprises slates and other low grade metamorphic rocks of sedimentary origin. Thus perhaps the simplest explanation of the heat flow pattern is that it maps out areas beneath which sediments of differing bulk heat production are preserved. Such differences could reflect either the provenance or the depositional environment of the sediments. However, the contours of heat flow, in northern Britain (Fig. 1) at least, cut across apparently discrete depositional zones such as the Midland Valley and Southern Uplands of Scotland[30].

All the highest values of heat flow in Britain have been measured in holes penetrating granites with high heat production and several bodies of this kind occur at the surface in the southern high heat flow belt, and shallowly in the subsurface of the northern belt. The deep structure and possible connections between these bodies has been the subject of research for some time[31–33] and a possible explanation for the high heat flow zones is that they correspond to zones of high heat-production intrusions presumably associated with old orogenic belts. Note that all the granites are too old for there to be detectable effects associated with their original cooling after employment.

The systematic variations of chemical composition of acidic and intermediate igneous suites normal to the trend of such belts have been extensively studied[34] and have generally been related to special conditions associated with partial fusion of a descending lithospheric slab[34–36]. Thus the chemical anomalies implied by the high heat flow zones could be regarded as features introduced into the crust at the time of granitic magmatism. In the present cases the southern high heat flow belt would be a Hercynian feature and the northern zone a Caledonian feature following the trend suggested by Evans[11]. If it could be demonstrated that the northern belt was indeed continuous from the Lake District across the Southern Uplands to the Midland Valley of Scotland, its formation would clearly postdate the closing of the Southern Uplands crustal suture[30].

The correlation in Fig. 2 implies some degree of communication between heat production in granitic rocks and in slates, because the same scale length for heat production distribution applies to either rock type. It is envisaged that such communication could be either physicochemical, or purely physical, or most likely some combination of the two.

A chemical communication could be set up by the interchange of fluid between granites and their country rocks. The cooling of granitic bodies may induce groundwater circulations[37,38] which are able to scavenge incompatible elements, such as those responsible for heat production, from large volumes of country rock and reprecipitate them within the granites and their immediate surroundings. Figure 2 would imply that the scale length of the convective process, and hence the fluid interchange, was ~15 km. It is, however, unlikely that redistribution of heat production could, by itself, give rise to the observed heat flow belts. The pattern expected from such a process alone would be one in which zones of elevated flux were flanked by exactly compensating zones of depressed flux resulting from hydrothermal scavenging. In view of the observed generally low heat flow outside the belts the main effect of the granitic rocks is probably to provide initial enrichment to the belts.

A purely physical relationship between heat production distribution within granites and slates can be envisaged in a two-layer crust; the lower layer would consist of relatively dense rocks of uniform heat production within which granites are too buoyant to reside for the period of their crystallisation. The upper layer would comprise the slates themselves and their intrusive granitic stocks. On this interpretation (a similar one to that proposed by Smithson and Decker[38]) heat production in each rock type would be uniform at all depths within the upper

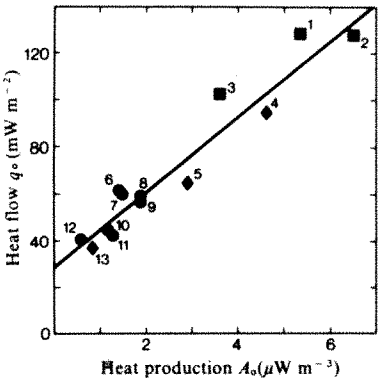

Fig. 2 Surface heat flow plotted against radioactive heat production in local granitic or low-grade metasedimentary and metavolcanic basement. Regression line: $q = 16.6A + 27$. Correlation coefficient $R = 0.96$. ■, Hercynian granites of south-west England. ◆, Lower Palaeozoic granites. ●, Cleaved phyllitic basement. Data for points, 1, 2, 4, 5, 7, 8, 9, 11, 12 and 13 are summarised in ref. 1. Point 3 is Longdowns[3]. Points 6 (Langstrothdale) and 10 (Montrose) (unpublished data). The slope and intercept of the correlation would be substantially unchanged were granitic rocks alone to be considered.

layer; the slope of the correlation in Fig. 2 is thus directly interpreted as the mean thickness of the upper layer.

Conclusions

We conclude that the main features of the heat flow field in mainland UK reflect lateral variations in the concentration of heat producing elements within the upper half of the crust. These in turn arise from the distribution of high heat-production granitic bodies which introduced heat production anomalies into an upper crust which was initially predominantly slaty in character. Although now cool the granites may, at the time of their intrusion, have initiated large scale convective circulations of water within the crust, which redistributed trace elements in sedimentary and igneous rocks alike. Enrichments in heat production might be expected to sustain some low-volume circulation over long periods of time. On a local scale the heat flow field is modified both by present day water flows and by heat flow refractions.

The relatively long scale length of the heat production distribution implies that near-surface temperature gradients in, for example, the Cornish granites should extend virtually unmodified to depths of several kilometres. Note that the same processes which redistribute heat-producing elements might also be expected to concentrate other elements in ore deposits. There is a weak correlation between the high heat flow areas and exposed zones of epigenetic mineralisation. This correlation may extend into areas where older rocks are hidden beneath a cover of Mesozoic and younger sediments.

We thank S. M. Wright, A. Martin, D. L. Loughman, M. Q. W. Jones and J. R. Bloomer for assistance and P. C. England for heat flow refraction calculations. The work is supported by research contracts from the EEC and the UK Department of Energy. We thank G. C. Brown for helpful comments.

Organisation and sequence studies of the 17-piece chicken conalbumin gene

M. Cochet, F. Gannon, R. Hen, L. Maroteaux, F. Perrin & P. Chambon*

Laboratoire de Génétique Moléculaire des Eucaryotes du CNRS, Unité 184 de Biologie Moléculaire et de Génie Génétique de L'INSERM, Institut de Chimie Biologique, Faculté de Médecine, Strasbourg, France

The conalbumin gene has been cloned and shown to consist of at least 17 exons approximately 60–200 base pairs long. The DNA sequence upstream from the region coding for the 5′ end of the mRNA shows similarities with sequences present in homologous positions in other genes. High and low frequency repetitive sequences are found both upstream from the conalbumin gene and within one intron.

CONALBUMIN (or ovotransferrin) is one of the major egg white proteins synthesised by the tubular gland cells of the magnum portion of hen oviduct. Its expression is controlled at the transcriptional level by oestrogens and progesterone, as are the other egg white proteins (see ref. 1 and refs therein). Nevertheless there are some differences in the patterns of expression of these genes after hormone administration. For instance, oestradiol administration results in a very rapid increase of conalbumin mRNA (con-mRNA), whereas the appearance of ovalbumin mRNA is somewhat delayed (see ref. 2 and refs therein). Comparison of the DNA sequences flanking these genes might

therefore provide a means of testing the idea that steroid hormones act (at least in part) through interactions of steroid–receptor complexes with the genome (see refs 3 and 4 and refs therein). In addition, the study of the conalbumin gene and its flanking sequences provides an interesting insight to the problem of tissue-specific expression of a unique gene[1].

Oviduct conalbumin and liver transferrin are the same protein, differing only in the nature of their carbohydrate moiety[5,6]. However, the modulation of the expression of the conalbumin-transferrin gene is very different in the two tissues. The expression of the oviduct gene is much more sensitive to oestradiol administration than is that in the liver, despite the presence of oestradiol receptors in chicken liver[7]. In addition, iron levels appear to be involved in regulating the expression of the gene in the liver, but not in the oviduct (G. S. McKnight, D. Lee and R. Palmiter, personal communication).

In previous studies we have constructed a recombinant plasmid containing a doubled-stranded cDNA (dscDNA) copy of con-mRNA (pBR322-con1, (ref. 8)) and have used it to investigate the structure of the conalbumin gene[1]. Restriction enzyme mapping of the genomic DNA revealed that the conalbumin gene is split and is contained in three *Eco*RI fragments, 5′-*Eco* 'b'-*Eco* 'c'-*Eco* 'a'-3′, about 4.0, 2.5 and 11.0 kilobase pairs long, respectively (see Fig. 1*A*(*b*); ref. 1) The *Eco*RI fragments 'b' and 'c' and about 1,500 base pairs at the 5′ extremity of fragment 'a' were cloned in the λ phage recombinant λC4-con1 and shown to contain the sequences coding for the first 940 nucleotides of the 2,400 nucleotide-long con-mRNA[1].

We now report the molecular cloning of the conalbumin *Eco*RI fragment 'a', which allows us to describe the organisation of the complete conalbumin gene. The DNA base sequence within and upstream from the region coding for the 5′ end of con-mRNA has also been obtained and the existence of repeated sequences within the conalbumin gene and upstream from its 5′ end is reported.

Cloning of conalbumin *Eco*RI fragment 'a'

Since previous attempts to isolate the complete *Eco*RI fragment 'a' from libraries representing the whole chicken genomic DNA had been unsuccessful[1], we decided to start from a DNA fraction enriched in this fragment. A recombinant, λWconA1, hybridising to a probe specific for fragment 'a', was isolated as outlined in the legend to Fig. 2. Digestion of this cloned DNA with *Eco*RI revealed the presence of a DNA fragment of a similar size to that of the genomic conalbumin *Eco*RI fragment 'a' (Fig. 2, lanes 1 and 2). Comparison (Fig. 2) of the restriction enzyme patterns obtained from the cloned and the partially purified cellular fragment 'a' digested with *Xba*I (lanes 3 and 4), *Bam*HI (lanes 5 and 6), *Bgl*I (lanes 8 and 9) and *Bgl*II (lanes 10 and 11), confirmed that the cloned fragment is indeed the conalbumin *Eco*RI fragment 'a'.

Combined with unpublished and previously reported mapping[1], the present restriction enzyme digestions allow the construction of the conalbumin gene restriction enzyme map shown in Fig. 1*A*(*b*). In addition, we have used (results not shown) the con-dscDNA probes, *Eco*A and *Eco*B (Fig. 1*B*(*a*)), *Eco-Bgl*I, *Eco-Bgl*II and *Eco-Bam*1 to localise, on the genomic DNA map, the *Eco*RI, *Bgl*I, *Bgl*II and *Bam*HI sites of con-dscDNA (Fig. 1*A*(*a*), (*b*)). The *Bam*2 site of the dscDNA (Fig. 1*A*(*a*)) was not found in the genomic clone. This discrepancy is accounted for by the existence of allelic variants for this *Bam*HI site (our unpublished results and D. Lee, G. S. McKnight and

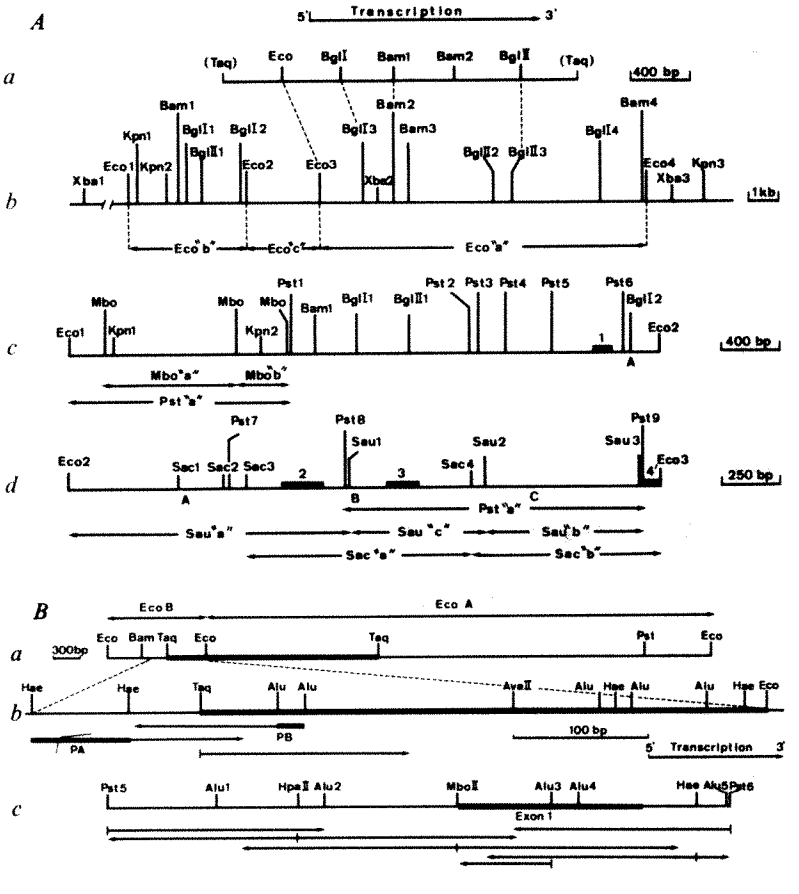

Fig. 1 *A*, Organisation of the sequences coding for conalbumin mRNA in chicken erthrocyte DNA and in genomic DNA clones. *a*, Partial restriction endonuclease map of the dscDNA copy of con-mRNA and scale in base pairs (bp) (taken from ref. 8). *b*, Restriction endonuclease map of the erythrocyte DNA region containing the conalbumin gene and scale in kilobase pairs (kb). This map extends from that previously published[1] to include the *Bam*HI, *Bgl*I and *Bgl*II sites. These sites were mapped (our unpublished results) using the previously cloned *Eco*RI fragment 'b' (ref. 1) and the presently cloned *Eco*RI fragment 'a' (see text and Fig. 2). The sequences coding for con-mRNA are contained in *Eco*RI fragments 'a', 'b' and 'c'[1]. The dotted lines between *a* and *b* indicate the correspondence between the restriction enzyme sites found in the dscDNA and the genomic clones (see text). *c*, Restriction endonuclease map of the cloned *Eco*RI fragment 'b' and scale in bp. For each restriction enzyme all of the existing sites are shown except for *Mbo*II where only the relevant sites are shown (see text and Fig. 6). The number 1 corresponds to exon *1* and A represents the 5′ moiety of intron *A*[1], *d*, Restriction endonuclease map of the cloned *Eco*RI fragment 'c' and scale in bp. A, B, C, 2, 3, and 4′ are the 3′ moiety of intron *A*, intron *B*, intron *C*, exon *2*, exon *3* and the 5′ moiety of exon *4*, respectively[1]. ***B*, Strategy for DNA sequencing at the 5′ end of conalbumin double-stranded cDNA and around exon *1* in the cloned genomic DNA.** *a*, Partial restriction enzyme map of pBR322-con1[8] linearised with *Eco*RI and scale (in bp). The heavy line corresponds to the inserted con-dscDNA. The two *Taq*I sites were generated during the insertion of the con-dscDNA in the *Sal*I site of pBR322[8]. *Eco*A and *Eco*B correspond to the fragments which are generated by *Eco*RI digestion of pBR322-con1[1,8]. *b*, DNA sequencing at the 5′ end to con-dscDNA and scale (in bp). The pBR322-con1 fragment *Eco*B (see *a*) was mapped by digestion with various restriction enzymes either singly or in combination and the restriction enzyme map of a selected region is represented. Due to the small size of the fragments resulting from *Alu*I digestions, it was necessary to label them at their 5′ end with [γ-^{32}P]-labelled ATP and T4 polynucleotide kinase in order to reveal them by autoradiography. Primers *A* and *B* (*PA* and *PB*) were prepared by acrylamide gel electrophoresis of *Alu*I or *Hae*III digests of purified fragment *Eco*B[1]. They were used to sequence around the *Taq* site by using the chain termination method of Sanger *et al.*[10] and the extent of the sequenced regions are shown by the arrows. The third arrow indicates the extent of the region sequenced from the *Taq* site using the method of Maxam and Gilbert[11] (*Taq-Eco* fragment end-labelled with [γ-^{32}P]-labelled ATP and cut with *Ava*II). *c*, DNA sequencing within and around exon *1* of the genomic DNA. The *Pst*5-*Pst*6 fragment of *Eco*RI fragment 'b' (1*Ac*) was subcloned in pBR322, isolated on sucrose gradient after *Pst*I digestion and mapped with various restriction enzymes as outlined under *b*. DNA sequencing was carried out using the Maxam and Gilbert method[11]. The arrows indicate the direction and the extent of the sequence determinations from the 5′ end-labelled restriction enzyme sites. When a given region was not sequenced on the two strands, it was sequenced at least twice on the same strand to ensure the accuracy of the sequence determination. The abbreviations used for restriction enzymes are for *Eco*RI, *Bam*HI, *Taq*I, *Pst*I, *Hae*III and *Alu*I. Sequencing gels and additional details about the strategy are available upon request. Scale as in Fig. 1*B*(*b*).

R. Palmiter, personal communication) similar to those which were previously described for the ovalbumin gene[9,12-15].

13 introns are present in the conalbumin *Eco*RI fragment 'a'

Seven conalbumin exons (*1–7*) separated by six introns (*A–F*) have previously been localised in *Eco*RI fragments 'b' and 'c' and in the previously cloned 1,500 base pair long 5′ segment of fragment 'a' (see ref. 1, and Figs 1*A*(*b*) and 4*f* and *g*). The cloning of fragment 'a' allows one to determine whether the ~2,000 nucleotides of con-mRNA which are not encoded in *Eco*RI fragments 'b' and 'c' are completely encoded in fragment 'a'.

Electron microscopy of hybrid molecules formed between con-mRNA and the cloned genomic *Eco*RI fragment 'a' reveals that con-mRNA hybridises to *Eco*RI fragment 'a' over 2,048 ± 184 nucleotides in 14 exonic RNA–DNA hybrid regions (*4″–17*), separated by 13 intronic single-stranded DNA loops (*D–P*) (Figs 3*A* and 4*b*). As expected from our previous results[1] the length measurements show that the first 1,500 base pairs at the 5′ extremity of fragment 'a' contain the previously identified introns *D*, *E* and *F*, the 3′ moiety of exon *4* and exons *5* and *6*. These observations definitely prove that the conalbumin *Eco*RI fragments 'c' and 'a' are contiguous. The organisation and the length of the various exonic and intronic sequences present in *Eco*RI fragment 'a' are given in Fig. 4*b*, *g*.

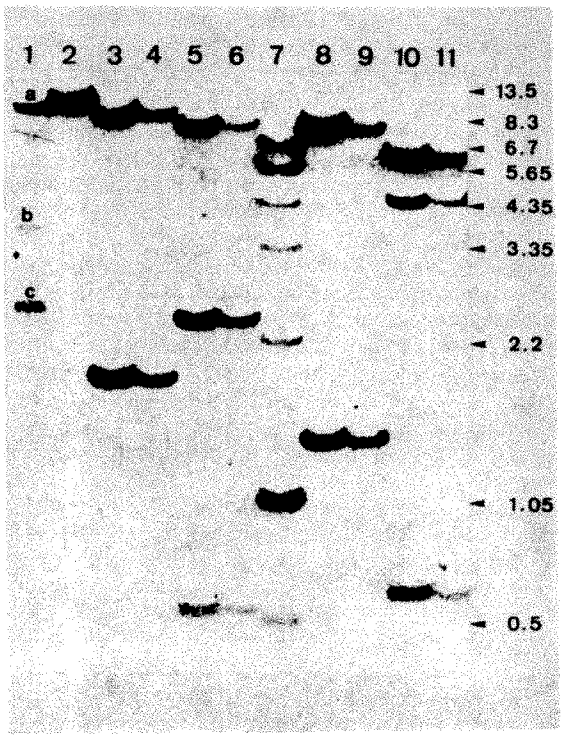
There is excellent agreement between the restriction enzyme map and the electron microscopic map. From the comparison of these two maps (Fig. 4*a*, *b*) one can predict that the restriction sites *Bam*2, *Bam*3 and *Bgl*II2 should be located in exon *9*, intron *I* and intron *N*, respectively. These predictions were verified by hybridising con-mRNA with specific restriction enzyme segments (Fig. 3). For instance, hybridisation with the *Eco*3-*Bam*2 and the *Bam*3-*Bam*4 fragments (Fig. 4*a*) allows one to localise *Bam*2 and *Bam*3 sites in exon *9* and in intron *I*, respectively (Figs 3*B* and 4*c*, *d*). Hybridisation of con-mRNA with *Eco*3-*Bgl*II2 fragment (Fig. 4*a*) indicates that site *Bgl*II2 is located in intron *N* (Figs 3*C*, 4*e*). Also, the *Bgl*I3 and *Bgl*II3 exonic sites (see above and Fig. 1*A*(*a*), (*b*)) appear to be located in exons *7* and *16*, respectively (Fig. 4*a*, *b*).

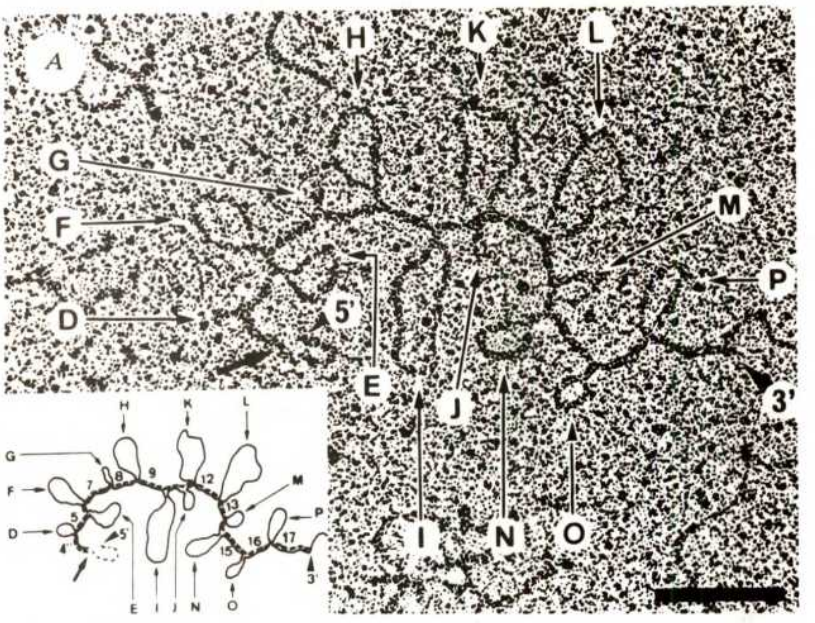
The conalbumin gene is in 17 pieces

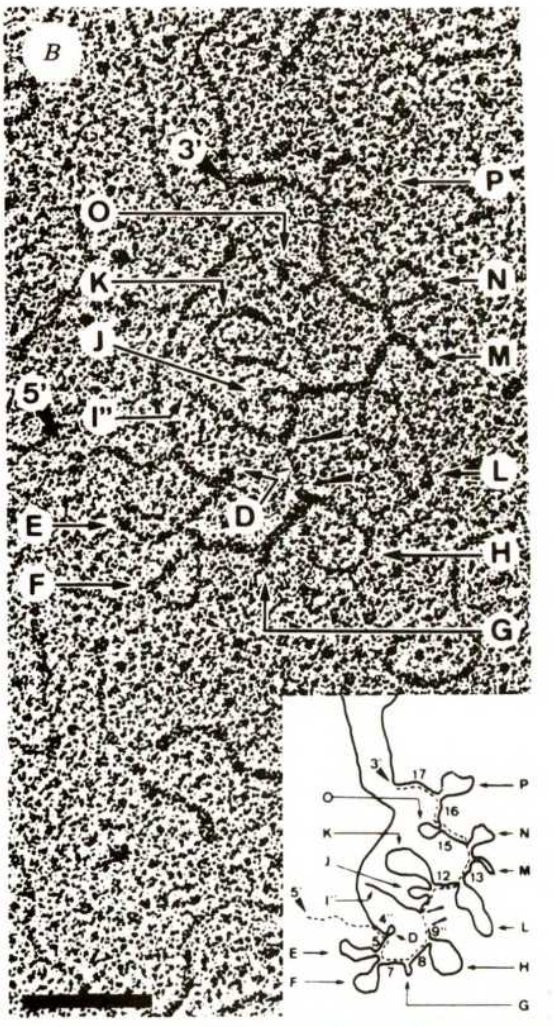
From our present and previous results[1], it appears that the conalbumin gene consists of at least 17 exons separated by 16 introns (we cannot exclude the existence of additional introns too small to be detected by electron microscopy). This striking structure is visualised in Fig. 3*D* in the form of a hybrid molecule between con-mRNA and the linked cloned conalbumin *Eco*RI fragments 'b', 'c' and 'a'. Seventeen exonic RNA–DNA hybrid regions (*1–17*) separated by 16 intronic, single-stranded DNA loops are visible (Figs 3*D*, 4*f*, *g*). The length of the entire DNA–RNA hybrid region is 2,508 ± 164 base pairs, in very good agreement with our previous estimate of con-mRNA length of about 2,400 nucleotides[8]. Since there is no clearly visible tail at the 3′ end of the hybrid region (see also Fig. 3*A*, *B*) despite the existence of a poly(A) sequence attached at the 3′ end of con-mRNA, it is very likely that exon *17* contains the DNA sequence coding for the 3′ end of con-mRNA. Exon *1* contains the DNA sequence coding for the 5′ end of the mRNA (see below). It appears therefore that con-mRNA is entirely encoded in the 10.3 kb genomic region which is between the 5′ end of exon *1* and the 3′ end of exon *17*. This conclusion is supported by the observation (M. LeMeur and A. Krust, personal communication) that the longest con-mRNA precursor molecule which which can be found in oviduct RNA is 9,900–10,100 nucleotides long.

The 5′ end of conalbumin mRNA is encoded in exon *1*

Since the sequence of con-mRNA was totally unknown and we previously showed that the con-dscDNA plasmid pBR322-con1







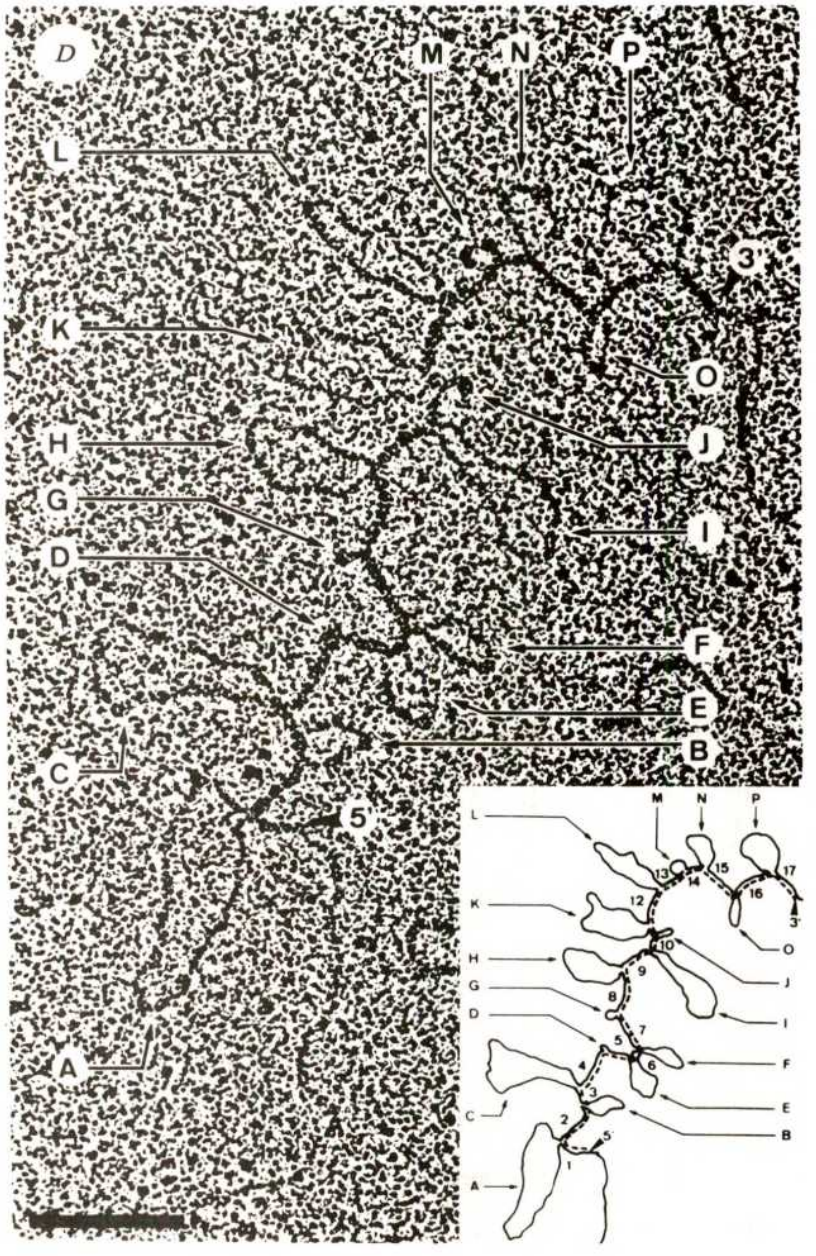


Fig. 2 Comparison of restriction enzyme fragments obtained from the cloned and partially purified cellular *Eco*RI fragments 'a'. The cloned *Eco*RI fragment 'a' was obtained as follows: 0.25 μg of an *Eco*RI digest of erythrocyte DNA partially purified by two cycles of RPC-5 chromatography[9] and sized by sucrose gradient centrifugation, was ligated with 0.6 μg of λgtWES.λC right and left arms and subsequently packaged and cloned as previously described by Garapin *et al.*[16] using the conalbumin dscDNA probe specific for the sequences coded for by *Eco*RI fragment 'a' (*Hha* B probe[1]). Out of 10,000 recombinants which were screened, one (λWconAI) hybridised to the probe and was amplified. About 2 μg of RPC-5 partially purified erythrocyte DNA (see above) (lanes 3, 5, 8, 10) and 0.3 ng of an *Eco*RI digest of λWconA1 DNA (lanes 4, 6, 9, 11) were digested with *Xba*I (lanes 3 and 4), *Bam*HI (lanes 5, 6), *Bgl*I (lanes 8 and 9) and *Bgl*II (lanes 10 and 11), electrophoresed on a 1% agarose slab gel, transferred onto nitrocellulose filters, hybridised with ^{32}P-labelled con-dscDNA probe pBR322-con1[8] and revealed by autoradiography as previously described [1,17]. Lanes 1 and 2 contained an *Eco*RI digest of total erythrocyte DNA (15 μg) and λWconA1 DNA (0.3 ng), respectively. ('a', 'b' and 'c' indicate the position of the three genomic *Eco*RI fragments.) Lane 7: hybridising size markers derived from pBR322-con1 plasmid. The size of the hybridising fragments (in kilobases) are: Lane 1: (a) 11, (b) 4, (c) 2.5; lane 2: 11; lanes 3 and 4: 9.1 and 1.9; lanes 5 and 6: 8, 2.45 and 0.55; lane 7: 6.7, 5.65, 4.35, 3.35, 2.2, 1.05 and 0.5; lanes 8 and 9: 7.9 and 1.45; lanes 10 and 11: 5.8, 4.6 and 0.6.

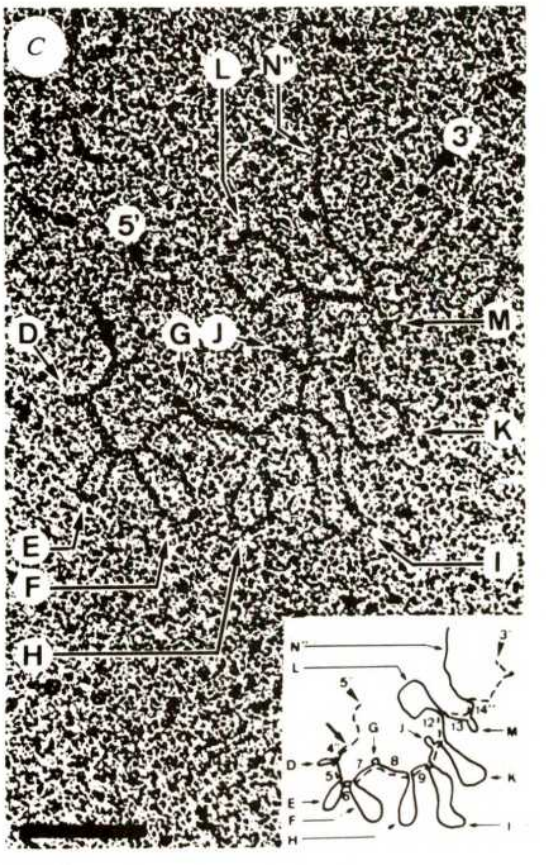

[Fig. 1*B*(*a*)] should contain most of the sequences corresponding to the 5′ end of the mRNA[8], we first sequenced the 5′ end of con-dscDNA. The sequence shown in Fig. 5*A* was obtained using the Maxam and Gilbert[11] and Sanger *et al.*[10] methods as outlined in the legend to Fig. 1*B*(*b*). The first possible AUG initiation codon is found 57 base pairs downstream from the 5′ end of the dscDNA. This AUG codon is the initiation codon for conalbumin, since it is followed (with one exception, see below) by the sequence coding for the 19 amino acids present at the N-terminal of pre-conalbumin (protein leader sequence, or signal peptide[6]) and the first amino acid (alanine)[6,18] of mature conalbumin. There is one difference at position −2 of the leader sequence of amino acids between our version derived from DNA sequencing and that of Thibodeau *et al.*[6] obtained by amino acid sequencing. This discrepancy does not seem to be related to DNA or protein sequencing inaccuracy (R. Palmiter, personal communication) and may reflect the existence of two allelic variants of the conalbumin gene similar to those mentioned above for *Bam*HI site.

Since it was very likely that the DNA sequence corresponding to the 5′ end of the dscDNA would be found in the genomic exon *1*, we sequenced the *Pst*5-*Pst*6 fragment of *Eco* 'b' which

contains exon *1* [Fig. 1*A*(*c*) and *B*(*c*)]. The sequence is presented in Fig. 5*A*. As expected, we found a region where the genomic and the dscDNA sequences were identical. This region, which contains the *Alu*3 and 4 sites, codes for the first 14 amino acids of the protein leader sequence. The limit between exon *1* and intron *A* is given by comparing the cellular and the dscDNA sequence (dashed line). The exonic–intronic junction sequence resembles the model sequence[19] which was derived by comparing several exon–5′-intron junction sequences and, once again, the dinucleotide GT is present at the 5′ end of an intron, in agreement with the 'GT-AG rule'[19].

Although the above results confirmed that exon *1* contains sequences coding for the 5′ region of con-mRNA, sequencing the 5′ end of the mRNA was necessary to determine the location of the 5′ extremity for exon *1* and whether it contains the sequence coding for the 5′ end of the mRNA. The sequence of the 5′ end of con-mRNA was obtained by using the genomic *Alu*3-*Alu*4 fragment [see Fig. 1*B*(*c*)] as a primer and the modified chain termination method of Sanger *et al.*[10,20] in order to sequence reverse transcripts of mRNA (see legend to Fig. 5*B*). With the exception of the first nucleotide, the sequence of the first 60 nucleotides of the mRNA was obtained and is presented in Fig. 5*A*. A sequencing gel corresponding to the first 36 nucleotides is shown in Fig. 5*B*. The first nucleotide of the mRNA cannot be determined with this method and the band which is present in all four lanes (lanes 1–4 of Fig. 5*B*) above the first U corresponds presumably to the first nucleotide of the mRNA as indicated by the position of an [*Alu*3-*Alu*4]-primed reverse transcript of the mRNA synthesised in the absence of dideoxynucleoside triphosphates (Fig. 5*B*, lane 5). The first nucleotide of the mRNA should therefore be an A by comparison with the cellular DNA sequences shown in Fig. 5*A*. The nature of the first nucleotide of the mRNA was confirmed as follows: an *Alu*2-*Alu*3 fragment end-labelled with [γ-^{32}P]-labelled ATP and polynucleotide kinase, was hybridised to con-mRNA under conditions which favour DNA–RNA hybrid formation[21], digested with S_1 nuclease, and electrophoresed on an acrylamide gel under denaturating conditions in parallel with the chemically cleaved products for DNA sequencing according to Maxam and Gilbert[11] of the same region. The migration of the major S_1-protected fragment corresponds to the T, which in the coding strand of the genomic sequence, is complementary to the A numbered 1 in the non-coding strand (Fig. 5*A*) (R. Hen, unpublished result). The first nucleotide of con-mRNA is therefore probably an A. However, direct RNA sequencing will be required to definitely establish the 5′ end sequence of con-mRNA. From the present study we conclude that exon *1* contains the sequence coding for the 5′ end of con-mRNA and that there is a 76 nucleotide-long untranslated region at the 5′ end of con-mRNA. Therefore con-mRNA, in contrast to ovalbumin and some viral mRNAs (see refs 19 and 24 and refs therein), but like other eukaryotic mRNAs, do not have an untranslated leader sequence encoded in a separate exon at its 5′ end.

Presence of repetitive sequences within and around the conalbumin gene

None of the conalbumin mRNA-coding sequences is repeated in the chicken genome[1]. Studies on the ovalbumin[9,16] and globin[22] genes have shown that the intronic sequences of these genes are also unique. In contrast, when a restriction enzyme digest of total chicken DNA is blotted onto a nitrocellulose filter and hybridised with either conalbumin *Eco*RI fragment 'b' or 'c' labelled by nick-translation, a very fast and complete darkening of the autoradiographic film is observed (not shown). This indicates the presence of highly repetitive sequences in both the *Eco*RI fragments.

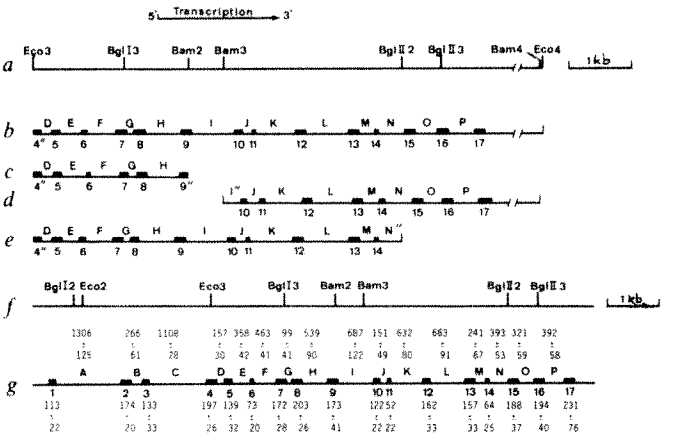

Fig. 4 Schematic representation of the hybrid molecules between con-mRNA and cloned genomic DNA fragments as measured by electron microscopy. *a*, Restriction enzyme map of conalbumin *Eco*RI fragment 'a' (see Fig. 1*A*(*b*)) and scale in kb for *a*–*e*. *b*, Localisation of exonic and intronic sequences contained in cloned *Eco*RI fragment 'a' (see Fig. 3*a*). Heavy lines (*4″* and *5–17*) refer to DNA–RNA hybrid (3′ moiety of exon *4* and exons *5–17*, respectively) regions. *D–P* correspond to single-stranded intronic loops. The length of the exonic sequence *4″* is 119 ± 29 base pairs and those of exon *5–17* are given under *g* together with the lengths of introns *D–P*. *c*, *d*, Localisation of exonic and intronic sequences within the *Eco*3-*Bam*2 and *Bam*3-*Bam*4 fragments (see Fig. 3*b*). Notation as under *b*, except for *9″* (the 5′ moiety of exon *9*) and *I″* (the 3′ moiety of intron *I*). The lengths of *4″*, *9″* and *I″* are 140 ± 22, 87 ± 44 and 296 ± 60 base pairs, respectively. The lengths of the other exons and introns are as shown in *g* within the experimental error. *e*, Localisation of exonic and intronic sequences within the *Eco*3-*Bgl*II2 fragment (see Fig. 3*c*). Notation as under *b* except for *N″* (the 5′ moiety of intron *N*). The lengths of *4″* and *N″* (in base pairs) are 113 ± 30 and 358 ± 94, respectively. The lengths of other exons and introns are as under *g* within experimental error. *f*, Restriction enzyme map of the conalbumin gene region (see Fig. 1*A*(*b*) and scale in kb for *f* and *g*. *g*, Localisation of the exons and introns in the conalbumin gene as established from the present data and those previously reported for the cloned conalbumin *Eco*RI fragments 'b' and 'c' and the 5′ moiety of *Eco*RI fragment 'a'[1]. Letters *A–P* and numbers 1–17 (heavy lines) correspond to the conalbumin gene introns and exons, respectively. The length of the exons *5–17* and of introns *D–P* are taken from the measurements made on 25 hybrid molecules similar to that shown on Fig. 3*a*, whereas the length of exons *1–4* and introns *A–C* are taken from Perrin *et al.*[1].

Fig. 3 Electron micrographs of hybrids between conalbumin mRNA and cloned genomic DNAs. The hybrid molecules were prepared as described previously[1]. In the line drawings, the dashed line represents the RNA and the solid line the DNA. Capital letters refer to intronic sequences, and numbers to the exonic RNA–DNA hybrid sequences (for the sake of clarity not all of the exons are numbered in the line drawings). The 5′ and 3′ ends of the con-mRNA molecules are indicated with arrows. ***a*, Hybrids between con-mRNA and heat-denatured cloned *Eco*RI fragment 'a' purified from λWconA1 DNA.** The RNA–DNA hybrids (2,048 ± 184 base pairs) are interrupted by 13 single-stranded DNA loops (*D–P*) (see line drawings and Fig. 4*b*). The length of the 3′ moiety of exon *4* (*4″*) and those of exons *5–17* together with the length of introns *D–P* are given in Fig. 4*b*, *g* and their legends. The unnumbered arrow points to the 5′ end of the RNA–DNA hybrid region which corresponds to site *Eco*3 (see Fig. 4*a*, *b*). ***b*, Hybrids between con-mRNA and heat-denatured *Eco*3-*Bam*2 and *Bam*3-*Bam*4 fragments of the cloned *Eco*RI fragment 'a'.** The *Eco*3-*Bam*2 fragment (Fig. 4*a*) was subcloned in pBR322 and the recombinant plasmid was linearised with *Bam*HI before heat-denaturation. The *Bam*3-*Bam*4 fragment (Fig. 4*a*) was subcloned in pBR322 and excised with *Bam*HI before heat-denaturation. The fragment *Eco*3-*Bam*2 contains introns *D–H*, the 3′ moiety of exon *4*(*4″*), exons *5–8* and the 5′ moiety of exon *9*(*9″*) (see line drawing and Fig. 4*c*), whereas fragment *Bam*3-*Bam*4 contains the 3′ moiety of intron *I*(*I″*), introns *J–P* and exons *10–17* (see line drawing and Fig. 4*d*). The two unnumbered arrows delimit the regions of the mRNA encoded by the 3′ moiety of exon *9* which is contained in the *Bam*2-*Bam*3 fragment (Fig. 4*a*, *b*) which was not present in this hybridisation. Length measurements are given in the legend to Fig. 4*c*, *d*. ***c*, Hybrids between con-mRNA and heat-denatured *Eco*3-*Bgl*II2 fragment of cloned *Eco*RI fragment 'a'.** The *Eco*3-*Bgl*II2 fragment (Fig. 4*a*) was prepared by digestion of the purified cloned *Eco*RI fragment 'a'. The hybrid regions contain the 3′ moiety of exon *4*(*4″*), exons *5–14* and introns *D–M* and the 5′ moiety of intron *N*(*N″*). (See line drawing and Fig. 4*e* for length measurements.) The unnumbered arrow points to the 5′ end of the RNA–DNA region which corresponds to the *Eco*3 site. ***d*, Hybrid between con-mRNA and the cloned conalbumin gene.** Hybrids were formed between con-mRNA and the heat-denatured complete conalbumin gene plasmid pBcon2 which was constructed from a modified pBR322 vector (containing a *Kpn*I site) by inserting the *Kpn*2-*Eco*3 fragment (Fig. 1*A*(*b*)) and the *Eco*RI fragment 'a' in the genomic order (M. Cochet, unpublished results). *Eco*RI fragment 'a' was purified from λWconA1, whereas the *Kpn*2-*Eco*3 fragment was obtained from λWconP5[1]. The hybrid region (2,508 ± 164 base pairs, 12 hybrid molecules were measured) contains all of the conalbumin exons *1–17* separated by the intronic loops *A–P* (see line drawing). In all cases the bars represents 0.1 μm.

These sequences were localised by restriction enzyme mapping using, as nick-translated probes, the two fragments and the total chicken DNA. Fragment *Eco* 'b' hybridises with both *Eco* 'c' (Fig. 6*A*, lane 1) and cellular DNA (Fig. 6*A*, lane 4) probes. The region which hybridises with both probes is localised in the *Pst* 'a' fragment [Fig. 6*A*, lanes 2 and 5, and Fig. 1*A*(*c*)]. However, the *Eco* 'c' probe hybridises only with the *Mbo* 'b' fragment [Figs 6*A*, lane 3; 1*A*(*c*)], whereas the cellular DNA probe hybridises strongly with fragment *Mbo* 'a' and only slightly to fragment *Mbo* 'b' [Fig. 6*A*, lane 6 and Fig. 1*A*(*c*)]. From these results we conclude that in a region located 2,000–3,200 base pairs upstream from the 5′ end of the conalbumin gene there is a highly repetitive sequence localised in fragment *Mbo* 'a' and a sequence situated in fragment *Mbo* 'b', which is repeated in *Eco* 'c', but not repeated very often in the rest of the genome. (We use the term highly repetitive, because these sequences must be repeated several hundreds of times in the genome for the total chicken DNA to be used as an efficient hybridisation probe in blotting experiments.)

Similarly, fragment *Eco* 'c' hybridises with *Eco* 'b' (Fig. 6*B*, lane 1) and cellular DNA (Fig. 6*B*, lane 4) probes. The region which hybridises with probes is localised in the *Pst* 'a' fragment of fragment *Eco* 'c' [Fig. 6*B* lanes 3 and 6, and Fig. 1*A*(*d*)], but the *Eco* 'b' probe hydridises only with the fragment *Sac* 'a' [Fig. 6*B*, lane 2, and Fig. 1*A*(*d*)], whereas the cellular DNA probe hydridises essentially with fragment *Sac* 'b' [Fig. 6*B*, lane 5, and Fig. 1*A*(*d*)]; on longer exposure exposure a faint hydridisation to fragment *Sac* 'a' was observed). From these results we conclude that the 3′ moiety of intron *C* [fragment *Sac* 'b', Fig. 1*A*(*d*)] contains a highly repetitive sequence, whereas the sequence which is similar to that present in the *Mbo* 'b' fragment of *Eco* 'b' is located in the 5′ moiety of intron *C* or in the 3′ moiety of intron *B* and is not repeated very often in the rest of the genome. Also, since the highly repetitive sequence present in *Eco*RI fragment 'b' is not revealed by *Eco* 'c' probe and conversely, our results demonstrate that the highly repetitive sequences contained in the conalbumin *Eco*RI fragments 'b' and 'c' belong to two different families of repetitive sequences.

It is interesting to compare our results with those recently reported by Eden and Hendrick[23], who found, by reassociation kinetic studies, that the repetitive chicken DNA can be divided into two classes based on repetition frequency: about one-third of the sequences are repeated 15-fold and two-thirds are repeated 1,500-fold. Also, they found that 40% of the chicken genome is arranged in an alternating pattern of single copy and repetitive sequences, with single copy regions of about 4,500 nucleotides in length, whereas almost one-half of the DNA consists of very long single copy regions, uninterrupted by repeated sequences for distance at least 17,500 base pairs. The two highly repeated sequences probably belong to the class of sequences which are repeated about 1,500-fold in the genome. It is striking that they are separated by 4,500 base pairs of single copy DNA as predicted from the reassociation kinetic studies. In contrast, their length is much shorter than that predicted by Eden and Hendrick[23] (at most 600 to 900 base pairs, instead of 2,000 base pairs). In contrast, there is no highly repeated sequence in the 10-kilobase pair-long conalbumin *Eco*RI fragment 'a' (L.M., unpublished result). In this respect, it is

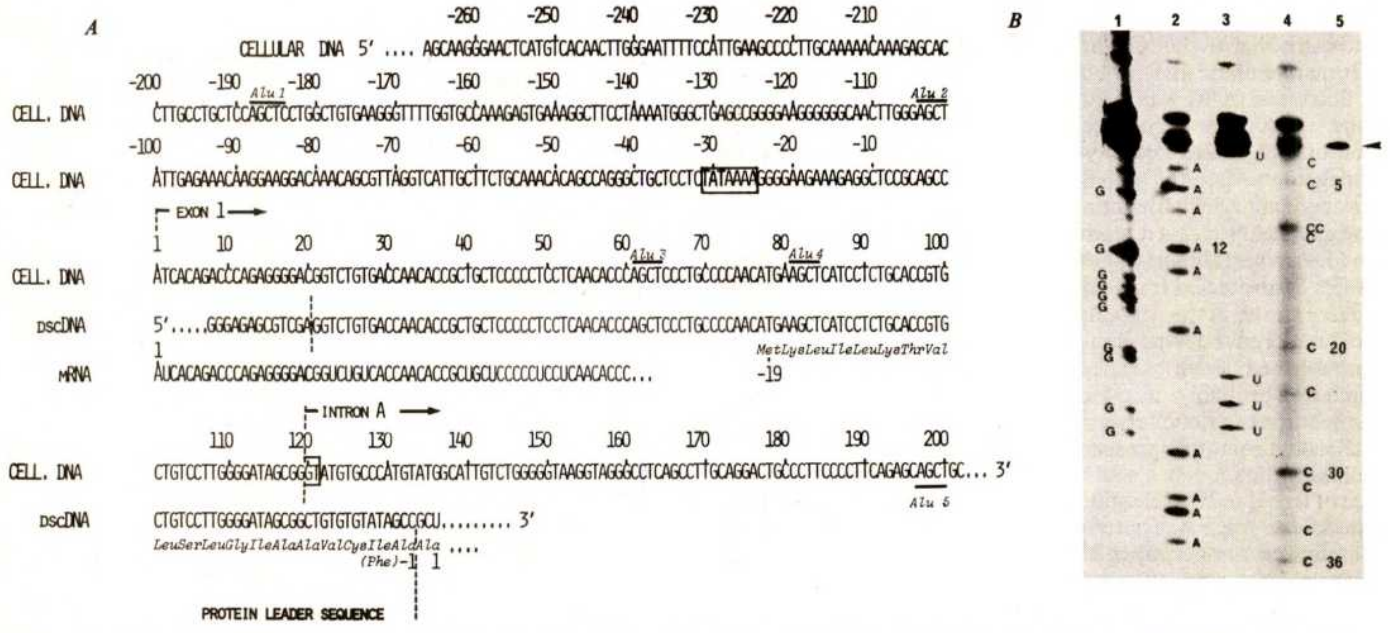

Fig. 5 ***A*, Comparison of nucleotide sequences at the 5′ ends of conalbumin double-stranded cDNA (dscDNA) and conalbumin mRNA (mRNA) with the corresponding sequences from genomic DNA (cell DNA).** The nucleotide sequences at the 5′ end of con-dscDNA and the genomic sequences within and around exon *1* were established as outlined in Fig. 1*B*. The first 60 nucleotides of con-mRNA were determined as described below and exemplified in *B* for the first 36 nucleotides. The DNA sequences (non-coding strand) were aligned with the mRNA sequence. The positive numbers refer to position of the nucleotides downstream from the 5′ end of mRNA, whereas negative numbers are given upstream from nucleotide number 1. The limit of exon *1* and of the 5′ end of intron *A* is shown in the genomic DNA sequences by a vertical dashed line. The dinucleotide GT[19] at the 5′ end of intron *1* is boxed. The positions of the *Alu*I sites (*Alu*1 to *Alu*5) shown in Fig. 1*B*(*c*) are indicated. The possible promoter AT-rich region (see text and Fig. 7*B*) is boxed. The limit separating the pBR322 sequence (TCGA corresponding to the *Taq*I site, see Fig. 1*B*(*b*) from the 5′ end of the dscDNA is indicated by a dashed line. The amino acid sequence of the protein leader sequence of pre-conalbumin[6] and the first amino acid of conalbumin are shown under the con-dscDNA sequence. A dashed line separates the protein leader sequence from the first amino acid (labelled 1) of the mature protein. The only amino acid difference (at position −2) between the sequence derived from the dscDNA and that obtained by amino acid sequencing[6] is indicated. ***B*, Autoradiogram of sequencing gel showing the sequence at the 5′ end of con-mRNA.** The sequence was obtained by the chain termination method of Sanger *et al.*[10] as modified by Akusjärvi and Petterson[20] in order to sequence reverse transcripts of mRNA. An *Alu*I digest of 0.3 μg of the genomic *Pst*5-*Pst*6 fragment (see Fig. 1*B*(*c*)) was denatured and hybridised with 60 μg of total hen RNA (purified on oligo dT-cellulose) as described in ref. 20, but for 1 h at 37 °C. The chain elongation (using [α-^{32}P]-labelled TTP) and the chase step were carried out at 37 °C as in ref. 20, but reverse transcriptase was added again before the chase step which was prolonged for 16 hours. Lanes 1–4 correspond to the reaction mixtures containing the dideoxynucleotides ddCTP, ddTTP, ddATP and ddGTP, respectively (the bases indicated in the figure correspond to those of the mRNA and are numbered from its 5′ end). The position corresponding to the first nucleotide of the mRNA was determined as follows: an *Alu*3-*Alu*4 fragment labelled at its 5′ ends with [γ-^{32}P]ATP and T4 polynucleotide kinase was purified by electrophoresis on a 8% acrylamide gel, hybridised to oligodT-cellulose purified hen RNA as above, and incubated with reverse transcriptase and the four deoxynucleoside triphosphates for 2 h at 37 °C. The elongated primer was run in lane 5 concomitantly with the sequencing reactions run in lanes 1 to 4, and after autoradiography yielded a single band (arrow head) indicating that the first nucleotide of the mRNA is the one just above the first U. The bands, which in lanes 1–4 are situated above the arrow head, correspond to elongation products of *Alu*1-*Alu*2 and *Pst*5-*Alu*1 fragments (see Fig. 1*B*(*c*)) which were present in the almost (but not fully) complete *Alu*I digest of the *Pst*5-*Pst*6 fragment used to prime in the reactions run in lanes 1 to 4 (see above). (These bands were not seen when purified *Alu*3-*Alu*4 fragment was used as a primer.)

interesting to recall the absence of repetitive sequences for more than 17 kilobase pairs within and around the ovalbumin gene[9,16,24]. The repetitiveness of the sequence which is common to *Eco*RI fragments 'b' and 'c' is unknown and the sequence might belong to the class of 15-fold repetitive sequences. It is interesting that in both cases they are situated close to highly repeated sequences. Current DNA sequence studies are further analysing these two classes of repeated sequences in an attempt to elucidate their relationship, if any.

Possible control regions at the 5′ end of conalbumin mRNA and around the 5′ end of the conalbumin gene

As for most eukaryotic mRNAs which have been sequenced up to now[25], the AUG codon located closest to the 5′ end of con-mRNA is the one used to initiate translation. Although the mechanism for translation-initiation site selection in eukaryotes is still unknown[25], the striking conservation of the 3′-terminal sequence of 18S RNA among eukaryotes led to the suggestion that this region of the 18S rRNA might base-pair with the complementary sequence of the initiation region in mRNA[26]. Complementarity between the 18S rRNA sequence, 3′-UAGGAAGGCGU-5′ and sequences of the 5′-non-coding regions of many eukaryotic mRNAs (see refs 25, 26 and refs therein), including ovalbumin mRNA[24,27] (Fig. 7*B*), has been recognised. In the case of conalbumin, there are two such possible regions of complementarity (Fig. 7*A*), although both are shorter than for ovalbumin mRNA. It is striking that, like ovalbumin, one of these regions is immediately preceded by a sequence which can form a base-paired loop (nucleotides 2–29). Although the existence of a 5′-terminal loop is not a general feature of eukaryotic mRNA, there is a similar hairpin structure at the 5′ end of SV40 VP1 mRNA[28]. The possible role of such hairpin structures in the capping and/or in the translation-initiation processes remains to be established by site-directed mutagenesis.

A putative AT-rich promoter region (Hogness box) for RNA polymerase B (or II) has recently been proposed on the basis of a comparison of DNA sequences from several genes and is located 23–25 base pairs upstream from the base coding for the first nucleotide of the mRNA (see refs 24, 29 and refs therein). Similarly, a possible promoter site is also present 25 base pairs upstream from the conalbumin cap site (Fig. 7*B*). When compared to other putative promoter sites[24], it is apparent that in most cases the AT-rich region is flanked on both sides by GC-rich segments, indicating that the final length of this possible eukaryotic promoter sequence will probably be very similar to that of the extended Pribnow box[30]. There is an amazing identity extending over 12 base pairs between the promoter sequence of the conalbumin gene and that of the major late adenovirus genes. In fact, this striking similarity is not limited to the Hogness box, but two additional regions of identity, 5 and 9 base pairs long, are found at positions −67 to −71 and −83 to −91, respectively. All of these identities, both in sequence and in position with respect to the cap site, cannot have occurred by chance and must correspond to common functional sites shared by these two evolutionarily distant genes. Again, site-directed mutagenesis studies will be required to investigate whether the regions of identity located upstream from the Hogness box could correspond to a site similar to the prokaryotic promoter recognition site[31]. In this respect, it is interesting that there are some similarities between the sequences present in these regions of the conalbumin and adenovirus late genes and sequences present in the corresponding regions of ovalbumin and other genes[32].

On the other hand, although there are some additional similarities in the region corresponding to the first 250 base pairs upstream from the cap site when comparing the ovalbumin and conalbumin gene sequences[24,32], they are, surprisingly, much less impressive than those noted above for the conalbumin and adenovirus late major genes. This result could indicate that there is no steroid hormone-mediated recognition of the DNA sequences present in this region. Alternatively, it may reflect the known difference of the ovalbumin and conalbumin genes in their hormonal response. Forthcoming sequence data for genes such as those for ovomucoid and lysozyme, and genes *X* and *Y* (refs 33, 34) whose hormone response is more like ovalbumin should be helpful in deciding between these two possibilities. Finally, although there is a striking similarity between the 10 residues which precede the cap site of adenovirus-2 late major and mouse β globin major genes[35,36], this homology sequence does not seem to be a general feature for eukaryotic messenger-coding genes, since it is absent from the conalbumin gene just as it is from other genes[24].

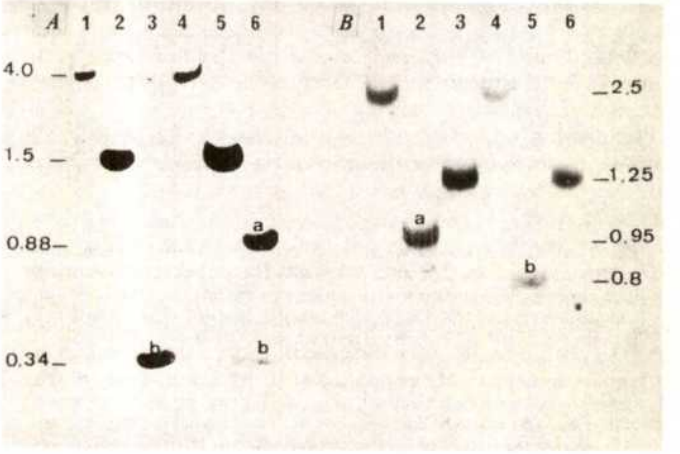

Fig. 6 Presence of repetitive sequences in the conalbumin *Eco*RI fragments 'b' and 'c'. *A*, Hybridisation of *Eco*RI fragment 'b' (lanes 1 and 4), and its *Pst*I (lanes 2 and 5) or *Mbo*II (lanes 3 and 6) digests with *Eco*RI 'c' fragment (lanes 1–3) or total cellular chicken DNA (lanes 4–6) labelled with ^{32}P by nick-translation. *B*, Hybridisation of *Eco*RI fragment 'c' (lanes 1 and 4) and its *Sac*I (lanes 2 and 5) or *Pst*I (lanes 3 and 6) digests with *Eco*RI 'b' fragment (lanes 1–3) or total cellular chicken DNA (lanes 4–6) labelled with ^{32}P by nick-translation. The intact *Eco*RI 'b' (0.2 μg) or *Eco*RI 'c' (0.2 μg) fragments and their restriction enzyme digests were electrophoresed on a 2% agarose slab gel, transferred to nitrocellulose filters, hybridised with the labelled probes and revealed by autoradiography as described in legend to Fig. 2. Exposure time for autoradiography was 3 days for lanes 1–6 of panel *A*, 6 days for lanes 1–3 of panel *B* and 1 day for lanes 4–6 of panel *B*. a And b refer to hybridising fragments [see text and Fig. 1*A*(*c*), (*d*)].

Evolutionary and functional aspects of the organisation of the conalbumin gene

The conalbumin gene represents the most striking example of a split gene described to date. It is remarkable that, like the ovalbumin[19,24], ovomucoid[37,38], lysozyme[39,40] and *X* and *Y*[33,34] genes, all of the conalbumin exons are short with sizes ranging from 50 to 200 base pairs. Any attempt to explain the emergence and evolution of split genes should take into consideration the small size and the high number of exons in these genes. In particular, it seems difficult to accept the idea (see ref. 41 and refs therein) that these genes have evolved from already distinct exons, each coding for a different structural domain, and that they were brought together in the genome by random shuffling. It is noteworthy that, although con-mRNA is only 25% longer than ovalbumin mRNA, the mRNA-coding portion of the conalbumin gene is in 17 pieces, whereas the ovalbumin gene is in eight pieces. In this respect the conalbumin gene is more like the ovomucoïd gene[37,38] which possesses at least seven exons for an mRNA of about 800 nucleotides. We have learnt from the study of the ovalbumin and the ovalbumin-related *X* and *Y* genes[33,34] that new split genes could have evolved by duplication of an ancestral gene which was already split in the same way. A similar conclusion was reached by analysing the structure of the α and β globin genes[42]. Such an origin of the conalbumin gene is

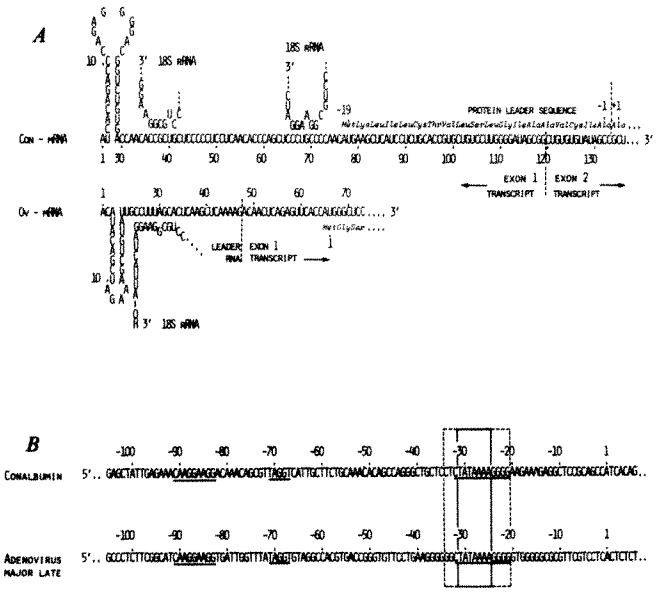

Fig. 7 *A*, Comparison between the 5′ end region of conalbumin (con-mRNA) and ovalbumin (ov-mRNA) mRNA. The con-mRNA sequence was taken from Fig. 5*A* and the ovalbumin sequence from Fig. 5 of ref. 24. The complementarity of con-mRNA with two sequences present at the 3′ end region of 18S rRNA is shown (see text). *B*, Comparison between DNA sequences (non-coding strands) of conalbumin and adenovirus-2 major late genes upstream from the regions coding for the 5′ end of the mRNAs (position 1). The AT-rich and GC regions of homology are boxed with a continuous and a dashed line, respectively. The lines below the sequences indicate the regions of identity between the two DNA sequences.

unlikely, since we found no evidence for sequences cross-hybridising with the conalbumin exonic DNA in the chicken genome. However, the determination of the amino acid sequence of human and of chicken transferrins has provided very strong evidence that doubling of an ancestral structural gene occurred during the evolution of transferrins (refs 43–45 and J. Williams, personal communication). It therefore appears more likely that the present day conalbumin gene has evolved by duplication of an already split ancestor gene (perhaps in seven or eight pieces, like the present day ovomucoïd gene). In this respect, the mechanism responsible for the appearance of the present day conalbumin gene could be similar to the duplication-fusion mechanism recently proposed by Sakano *et al.*[46] for the origin of the constant region of the mouse immunoglobulin γ1 heavy chain, except that in the conalbumin case the ancestral gene would already be a split gene. Clearly, the current detailed studies of the conalbumin gene structure should be very informative upon the question of how a new split gene may evolve by duplication of an ancestral split gene—a fundamental question, since gene duplication has perhaps been the predominant force involved in evolution[47].

It has been suggested that each exon might correspond to a functional or a structural domain (see ref. 41 and refs therein). Conalbumin provides an opportunity to test this idea, since the first 19 amino acids of pro-conalbumin belong to a functional domain which is involved in the secretion of the protein[6,48]. Although it is not known which amino acids are absolutely required for the secretion of the protein, 14 out of the 19 amino acids which constitute the protein leader sequence are encoded in exon *1* (Figs 5*A*, 7*A*). A similar situation is encountered in the case of the mouse immunoglobulin light chain genes where 15 out of the 19 amino acids which constitute the protein leader sequence are encoded in exon *1*[49,50]. It remains to be seen whether this correspondence between exon *1* and the possibly functional portion of the protein leader sequence is coincidental or reflects a general feature of the organisation of genes coding for secreted proteins possessing a protein leader sequence. The existence of two homologous iron-binding domains in transferrins[43–45,51] will provide an additional possibility to test the idea that exons could correspond to structural or functional domains.

Finally, the presence of repetitive sequences in intron *C* of the conalbumin gene is interesting in at least two respects. Firstly because, if the present day conalbumin gene has evolved by duplication of an ancestral split gene which was in seven or eight pieces, it is surprising that no repetitive sequences are found in the conalbumin *Eco*RI fragment 'a'. This absence might reflect the insertion of the repetitive sequences at a later stage during evolution or the loss of the duplicated counterpart. Secondly, the presence of these repetitive sequences should allow us to answer some questions related to their possible structural and/or regulatory role[52].

Biohazards associated with the experiments described in this publication were previously examined by the French National Control Committee. The experiments were carried out under L3-B1 conditions. We thank Dr R Breathnach for advice on DNA and RNA sequencing, Dr S. Tonegawa for a gift of λgtWES.λC arms, and A. Krust and M. LeMeur for gifts of conalbumin mRNA. We also thank C. Wasylyk, J. M. Garnier, E. Taubert, R. Fritsch, A. Landmann, B. Boulay, E. Badzinski and B. Chambon for technical assistance. This work was supported by grants from 3558 and 4160 CNRS, 75.5.468 INSERM and a grant from the Fondation pour la Recherche Médicale Française.

A composite DNA sequence of regions of hepatitis B virus, determined from a series of recombinant plasmids, reveals the genes for the surface antigen and the core antigen of the virus. The sequence of the core antigen shows it to be a DNA binding protein. The core antigen gene is expressed in Escherichia coli *and when injected into rabbits the bacterial product induces antibodies which react with core antigen isolated from human sources.*

DNA FROM hepatitis B virus (HBV) of three different serotypes has been cloned in *Escherichia coli* via phage λ derivatives[1,2] and plasmids[3,4]. Some of the transformed cells produce an antigen that reacts specifically with hepatitis B core antibodies (HBcAb)[3]; these cells contain hybrid plasmids, constructed by insertion of HBV DNA fragments into pBR322 at the R.*Pst*I cleavage site via 3′ oligo (dG) and oligo (dC) tails to facilitate the expression of viral antigen genes as polypeptides fused to β-lactamase[5]. Thus, the coding sequence of the HBV core antigen should be adjacent to or near the point of fusion to the β-lactamase gene. Nucleotide sequence analysis might identify HBV genes since the molecular weights of the core antigen (HBcAg) and surface antigen (HBsAg) are known[6,7], as are partial amino acid sequences from the N- and C-termini of HBsAg[8].

DNA fragment mapping and nucleotide sequence determination

The cloning of HBV DNA fragments isolated from blood plasma with the complex serotype *adyw* was described previously[3], together with some properties of some of the recombinant plasmids. The viral DNA has an unusual structure: there is a nick in one strand and a gap in the other[6]. Table 1 lists the plasmids chosen for sequence analysis and shows the sizes of the HBV fragments that they contain. All those plasmids imparting to their host cell the ability to synthesise core antigen, as detected in the solid phase radioimmunoassay[9], contained HBV sequences in the same orientation; in some cases this was confirmed by heteroduplex electron microscopy. Fragments were prepared from these plasmids by digestion with appropriate restriction enzymes and labelled at their 5′ termini with [γ-^{32}P]ATP and T4 polynucleotide kinase, and their nucleotide sequences were determined by the chemical degradative methods of Maxam and Gilbert[10]. Figure 1 outlines the sequencing strategy and Fig. 2 shows the composite sequence. The sequence shown covers about 87% of the virus; our set of clones has proved deficient in representations of the region of the gap in the viral DNA.

Table 1 HBV clones

HBcAg positive

Clones	Ala_{182}	Left endpoint	Phe	His	Right endpoint
pHBV64	GCA	$(GGG)_5GTT$	TTT	CAC	1,788
pHBV66	GCA	$(GGG)_6GAA$ CTT	TTT	CAC	~1,710
pHBV139A	GCA	$(GGG)_8GGA$ CTT	TTT	CAC	~1,260
pHBV110	GCA	$(GGG)_7CTT$	TTT	CAC	~1,240
	GCA	$(GGG)_6GGC$	TTT	TTC	
pHBV138	GCA	$(GGG)_5CTT$	TTT	CAC	1,842
pHBV139	GCA	$(GGG)_7CTT$	TTT	CAC	1,625

HBcAg negative

Clones	Left endpoint	Right endpoint
pHBV15	1,967	2,656
pHBV20	1,447	2,199
pHBV114	~−80	~2,270

The structure of the oligo (dG) stretch that fuses to Ala_{182} of β-lactamase is given for the HBcAg producing plasmids. Clone pHBV110 has two plasmids, one out of phase by one base.

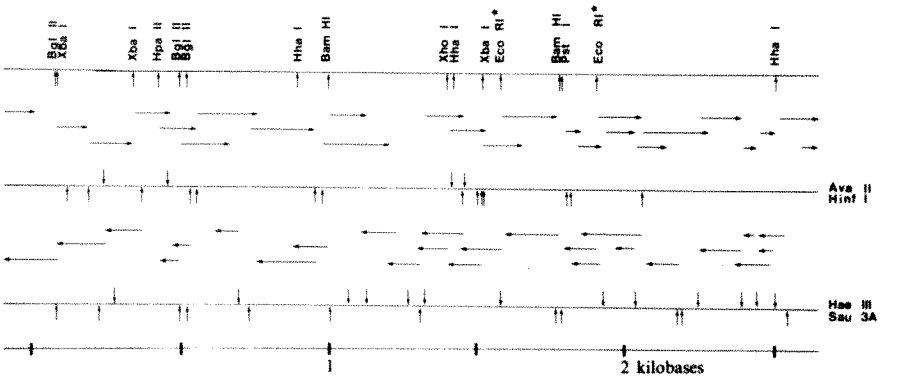

Fig. 1 The positions of restriction targets in HBV DNA and the strategy for nucleotide sequence determination. For simplicity the restriction targets are distributed between three maps, but each covers the same DNA sequence which, like the sequence shown in Fig. 2, begins at the point of attachment to the *Pst* site in pBR 322. Vertical arrows indicate the positions of restriction targets and the horizontal arrows show the direction and extent of the sequencing runs; the sequencing techniques were the chemical methods of Maxam and Gilbert[10].

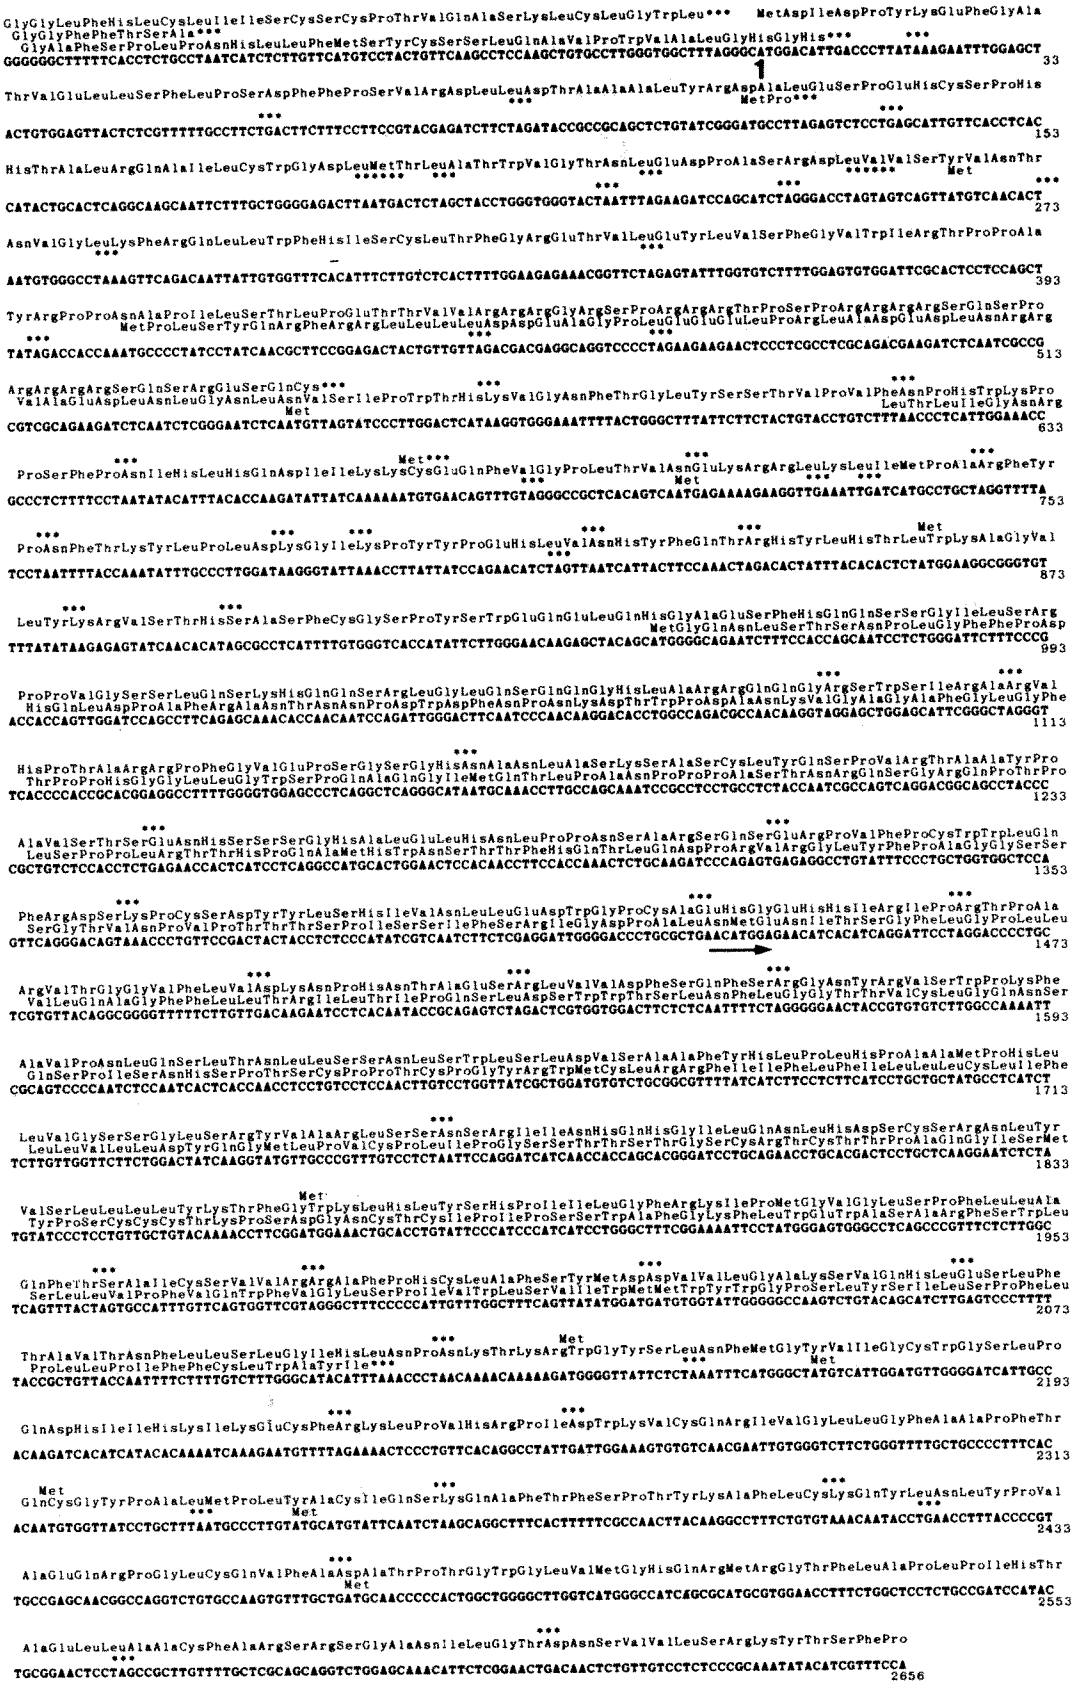

Fig. 2 The nucleotide sequence of HBV DNA shown as fused into pBR322 and expressing HBcAg (the first phase). The major possible translation products in all three reading frames are shown starting at the first ATG after a terminator***. The sequence is numbered from the A of the ATG for initiation of the core antigen as reference. Core antigen sequence runs from residues 1 to 549; the surface antigen is encoded between residues 1,437 and 2,114. The sequence was derived principally from clone pHBV138 and was extended by results derived from pHBV20 and pHBV15. The arrow shows the beginning of the sequence coding for HBV surface antigen. Several shorter translation products are possible, but have been omitted from the figure for simplicity.

The core antigen gene

All of the recombinants examined that produced HBcAg proved to have the HBV DNA insertion in the same phase with respect to the R.*Pst*I site in the β-lactamase gene beginning within one or two bases of the same sequence. Table 1 lists the structure of these junctures. Since the original HBV fragments came from digests with different restriction enzymes, R.*Bam*HI and R.*Kpn*I, this unique attachment was surprising. It may have resulted from inadvertant breakage, or tailing, of the DNA (from Dane particles) at the nick in the molecule[6]. We expected that the core antigen, in whole or in part, would be fused to β-lactamase via a small number of glycine residues, but that is not the case. In six strains that produce antigen, the β-lactamase is fused through 5 to 8 glycines to the same peptide sequence, but this sequence terminates 25 amino acids further on. In this phase the stop codon is followed three nucleotides later by an initiation sequence from which translation continues unhindered to give a polypeptide of 183 residues (Fig. 2, positions 1 to 549). Stop codons are abundant in the other two translation phases throughout this region.

Because there is a requirement for in-phase reading of this termination signal, the situation resembles the restart phenomenon observed in bacterial proteins. We conclude that the core antigenic activity resides in a polypeptide of molecular weight 21,000 translated *de novo* from the transcript of the viral DNA sequence. This product would probably remain within the cell, rather than be within the periplasmic space; this is consistent with our observations that HBcAg activity is only detected in bacterial extracts, not in osmotic 'shockates'.

The core antigen

Amino acid sequences for the *in vivo* core antigen have not been published, but the calculated size of the antigen resulting from translation of the nucleotide sequence carried in the bacterial plasmid is close to the molecular weight of 19,000 observed for the antigen isolated from Dane particles[6,7]. We do not know if any amino acids have been trimmed from the amino terminus of the authentic protein. The deduced polypeptide sequence is interesting; while the protein is not particularly remarkable in its amino-terminal half, sequences homologous with protamines and especially with galline[11] (from rooster sperm) are found towards the carboxy terminus (residues 150–183, nucleotides 448–549). In this region 16 out of 34 amino acids are arginines, arranged in groups of 3 or 4 separated by 4 other residues (Fig. 2). The sequence Ser-Pro-$(Arg)_3$ occurs three times, while there is a double repeat of the sequence Ser-Pro-$(Arg)_4$-Ser-Gln. The obvious inference is that the C-terminal region binds the HBV DNA within the Dane particles, while the rest of the protein participates in other structural roles. The four cysteine residues offer the possibility of internal disulphide bridges as well as intermolecular interactions, the latter possibly explaining some of the higher molecular weight values observed for HBcAg[6].

Although the structure of the messenger for HBcAg is unknown, we support the inference that the ATG at position one is the initiator by noting a secondary structure feature in the DNA sequence, and thus in a hypothetical mRNA, just before that ATG: a stem with a loop that could pair with the 18S ribosomal RNA analogous to structures that have been found in preproinsulin messages and some other higher cell mRNAs[12–14]. Figure 3 shows this feature. Although short oligonucleotide sequences that would possess a similar capacity for such interactions can be found elsewhere in the HBV DNA sequence, none can be related to an initiation codon in a simple way.

In vivo activity of the core antigen produced from *E. coli*

To test the biological activity of the antigenic polypeptide translated from the plasmid transcript, sterile extracts of the bacterial cells mixed with an equal volume of Freund's adjuvant were injected into rabbits. Two animals received the crude bacterial extract, and two were given samples of the same extract after fractionation on a Sephadex G-50 column. Additional injections of the same sample, which had been stored frozen and shown to retain full antigenic activity, were given 2 weeks and 5 weeks after the first injection, and the animals were bled at intervals several weeks after the initial injection. Figure 4 shows the results of immunodiffusion experiments[15] comparing these sera to human HBcAb (HBcAg positive), using HBcAg derived from human liver[16]. All four rabbit sera gave precipitin lines with HBcAg identical to those formed between this antigen and HBcAb derived from human sources. Thus, the core antigen synthesised in *E. coli* is serologically active *in vivo*. Regardless of whether antibodies to this particular antigen confer protection against HBV *in vivo*, the experiment does establish the feasibility of vaccine production from viral antigens synthesised in microbial cells.

Table 2 Amino acid composition for HBsAg

Serotype:	adw*	ayw3*	ayw†	adyw‡

The surface antigen gene

None of the hybrid plasmids used in the sequence analysis synthesised any surface antigen that could be detected by the radioimmunoassay. However, amino acid sequences of parts of HBsAg are known[8] so that a corresponding gene sequence could be sought along the DNA. Figure 2 shows such a sequence, starting at residue 1,437, which runs from the observed N

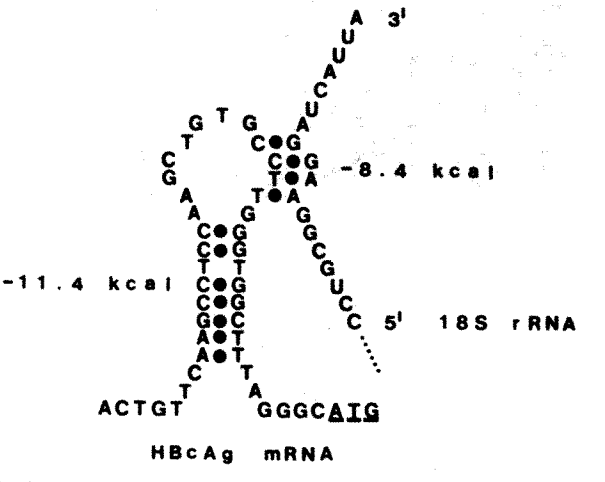

Fig. 3 A secondary structure feature lying immediately before the initiator of the core antigen which could pair with the 18S rRNA.

Table 3 Hepatitis B sequence heterogeneity

Gene/position of initial nucleotide	pHBV138	pHBV64	pHBV139	pHBV110	pHBV20	pHBV170

HBsAg/1,764	ATT Ile				CTT Leu	

terminus, Met-Glu-Asn-Ile-Thr-Ser- (ref. 8) to a terminator 226 amino acid residues away. We presume that this protein is initiated at the ATG at residue 1,437, but we cannot exclude the possibility that the mature protein is cleaved from a larger polypeptide initiated at the ATG at residue 948, since there is no termination codon between these two triplets. This polypeptide sequence, corresponding to a protein of molecular weight 25,400, also contains two peptide sequences of nearly identical composition to those for two amino-ethyl-cysteinyl peptides of 13 and 28 amino acids in length isolated after digestion of HBsAg with trypsin (D. L. Peterson, personal communication), as well as the correct C-terminal dipeptide[8], all in the same reading frame. The amino acid composition of HBsAg deduced from the nucleotide sequence is in accord with the results of analysis of the antigen itself (Table 2). The molecular weight of HBsAg in the glycosylated form has been estimated to be 25,000, while that of the nonglycosylated form of this polypeptide, which is also immunogenic, has been estimated to be 22,000[7,8]. There is one characteristic glycosylation sequence in this protein, the Asn in the third position, which lies in a . . . Asn-Ile-Thr-Ser . . . sequence[17]. The location in the cloned HBV DNA of a nucleotide sequence corresponding with amino acid sequences of HBsAg is strong evidence that the surface antigen is a viral gene product and not a host gene product induced by infection with the virus. The donor of the plasma used as a source of Dane particles for these clonings showed a complex serotype, a mixture of *adw* and *ayw*, and presumably was infected by two viruses. We have observed microheterogeneity between different clones. Table 3 lists these sequence variations (not exhaustively). Several of the variations are silent, or not in known products, but three changes occur in HBsAg, substitution of Ala for Val and Arg for Thr between clones pHBV138 and pHBV139 as well as a change of a Leu for Ile in a third clone, and these could reflect this complex serotype. The sequence heterogeneity of the different clones demonstrates that the infection involves a heterogeneous virus population. Furthermore, the gene for surface antigen extends into the region of the gap in the HBV DNA molecule and may be drifting rapidly.

The nucleotide sequence of the recombinant plasmids shows that none of those examined has the HBsAg gene in a position from which we would expect any biologically active polypeptide to be produced, and no HBsAg was detected. The sequence results immediately indicate subcloning experiments for the expression of the surface antigen as a polypeptide fused to β-lactamase. Some of the clones obtained from these experiments have given positive reactions in the radioimmunoassay for HBsAg.

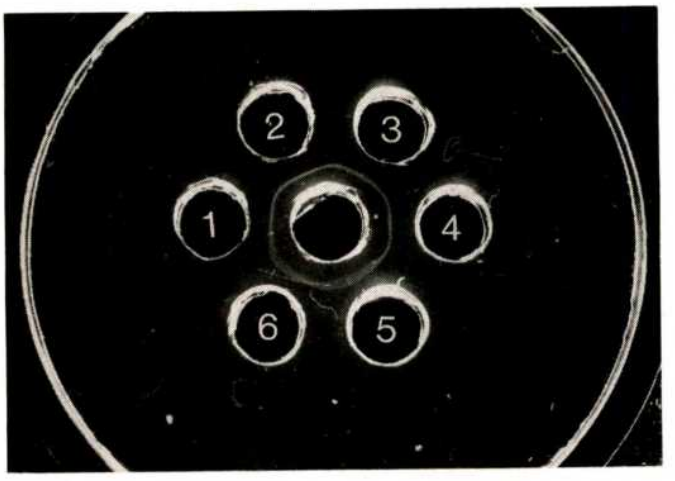

Fig. 4 An Ouchterlony immunodiffusion experiment comparing rabbit anti-(*E. coli*-HBcAg) to human anti-HBcAg in a 0.9% agarose gel in 0.01 M Tris-HCl *p*H 7.2, 0.001 M EDTA, 0.1M NaCl. The centre well contained partially purified HBcAg derived from human liver[16]. Wells 1 and 4 contained human HBcAb at a dilution of 1 in 30, wells 2 and 3 contained undiluted serum from rabbits injected with the unfractionated extract from bacteria carrying clone pHBV139, and wells 5 and 6 contained undiluted rabbit antiserum raised against HBcAg from the same bacterial extract, but fractionated on a column of Sephadex G-50. Equivalent results were also obtained in a solid phase radioimmunoassay.

Other HBV genes

In addition to the core and surface antigens, the *e* antigen (HBeAg) and the endogenous DNA polymerase of the Dane particle should be encoded in the viral DNA; however, little is known of their properties. The DNA sequence suggests that the viral information is encoded in overlapping readings in one direction. The largest translation produce encoded anywhere by the opposite DNA strand is 62 amino acids, while if the HBV nucleotide sequence is read in the third reading frame (with respect to core and surface antigen sequences), a translation product overlapping the C-terminal region of the core antigen as well as the entire gene for surface antigen continues for at least 750 amino acid residues (to nucleotide 2656 which is the extent of the sequence so far determined) and so could perhaps be a candidate for the DNA polymerase. Bacterial and viral DNA polymerases have molecular weight in the range 109,000–120,000[18,19], whereas that of the *e* antigen is probably around 19,000[20].

In this discussion we have assumed for simplicity that there is no important splicing of the viral RNA within the translated regions of the genome. However, a full understanding of the mechanism of expression of the viral genes must await an identification of the structure of the viral messages. Now that cloned fragments and DNA sequences of HBV are available, a complete unravelling of the molecular biology of this human disease is possible.

We thank U. Burghardt, C. J. Burrell, P. J. Greenaway, and also Tai-Kin Wong and P. H. Hofschneider (for supplying some of the DNA used for sequence analysis). Walter Gilbert is an American Cancer Society Professor of Molecular Biology. Since this manuscript was submitted for publication, nucleotide sequences of that part of the HBV genome corresponding to the surface antigen have been published by two other groups[22,23]. The identity of the surface antigen gene is strongly supported by the congruence of these results with ours, all three nucleotide sequences giving a polypeptide of the same size. Within the coding sequence of 678 nucleotides, the sequence given here differs in 15 positions from that in ref. 23 and shows 30 base changes from that in ref. 22. However, the three sequences are highly conserved in the regions corresponding with the N- and C-terminal domains of the surface antigen, while appreciably more than half of the base changes occur within the central region of the protein, many of them producing a change in amino acid. Sequences flanking the coding region are included in ref. 22 and much more difference from the sequence published here occurs in these flanking regions; some 15% of the bases differ in the region ahead of the coding sequence and about 11% in the region following it, compared with an average of 4% difference between the two sequences in the coding region.

Equilibrium: the intracellular distribution of steroid receptors

Peter J. Sheridan, James M. Buchanan & Vincent C. Anselmo

Department of Anatomy, University of Texas, Health Science Center at San Antonio, 7703 Floyd Curl Drive, San Antonio, Texas 78284

Pierre M. Martin

Laboratoire Recepteurs Hormonaux, Institut Paoli Calmette, Marseilles, France

Data are presented which suggest that there are unbound receptors for oestrogen in nuclei of the smooth muscle cells of the myometrium. A new model for the distribution of unbound receptors is proposed in which unbound receptor is in equilibrium, partitioned between nucleus and cytoplasm according to the free water content of these intracellular compartments.

THE most widely accepted model for the intracellular translocation of steroids was developed from many studies concerning the uptake and retention of oestradiol in cells of the female reproductive tract. According to this model, oestradiol enters the uterine cells, binds to a specific high-affinity cytoplasmic receptor and is then translocated to the nucleus by a temperature sensitive process. During this process, the oestrogen receptor undergoes a conformational change which is discernible by an increase in its sedimentation coefficient from 3.8–4S to 5–5.2S and by its ability to bind to isolated uterine nuclei and stimulate RNA synthesis[1–3]. However, there are data in the literature which question the validity of this model (for review see ref. 4). Briefly, free receptor and 4S receptor have been found in carefully washed nuclei[5–9], and the conversion of 4S to 5S has been shown to take place more rapidly in the presence of DNA[10]. Much of the support for the classical model for the intracellular translocation of steroids comes from autoradiographic studies conducted together with the early biochemical studies[11]. After a 1-h incubation at 37 °C the steroid was localised autoradiographically in the nucleus, agreeing with the biochemical data, whereas after a 5-min incubation at 2 °C the steroid was localised autoradiographically outside the nucleus. Close examination of the autoradiogram shown[11] does not reveal a cytosol concentration of steroid but rather a diffuse pattern resembling background. This interpretation does not agree with the corresponding biochemical data[11]. Because we were unconvinced by the autoradiogram and because in our hands whole uteri are subject to problems associated with diffusion and washing, we initiated experiments which we feel demonstrate unbound nuclear receptors in rat uterus and a breast tumour line. In addition, we propose a new model for the intracellular distribution of steroid receptors in which unbound receptor is in equilibrium, partitioned between cytoplasm and nucleus according to their respective free water content.

Autoradiographic studies: nuclear receptor at 4 °C

The immature rat uterus was studied in detail because it was used by the original investigators to establish the current model for the mechanism of action of steroids. A second system was used to confirm these results—cells from a breast tumour line designated MCF-7.

Whole uteri from 21–23-d-old rats (Sprague–Dawley) were incubated in minimal essential medium (MEM, GIBCO) in the presence of 5×10^{-9}M [1, 2, 6, 7-^{3}H]oestradiol-17β (89 Ci mmol^{-1}, Amersham/Searle) with or without 5×10^{-7} M unlabelled oestradiol (E_2, Sigma) for either 5 min or 2 h at either 0 or 37 °C. Identical incubations were carried out with ^{3}H-R2858([6,7-^{3}H]methoxy-17 ethyloestradiol, 52 Ci mmol^{-1}) or with ^{3}H-R2858 + unlabelled R2858. The tissue was then processed for autoradiography[12] to determine the location of the ^{3}H-steroid. Additionally, some tissues were incubated for 5 min at 0 °C and processed biochemically (see below). Nuclear local-

0028–0836/79/490579—04$01.00

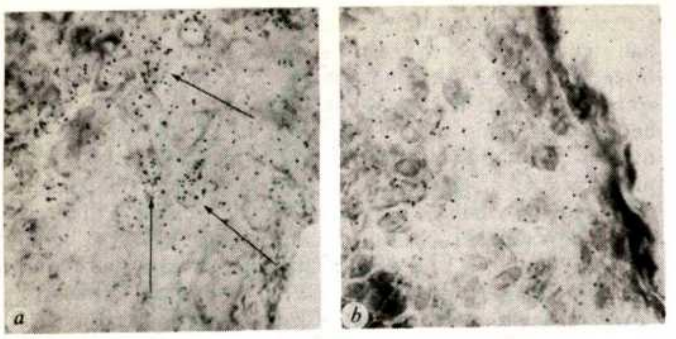

Fig. 1 Autoradiograms of rat uteri from the extreme periphery of the sections. The serosa appears to the right in both autoradiograms. *a*, Incubated at 0 °C for 5 min with ^{3}H-oestradiol-17β (5×10^{-9}M), *b*, incubated at 0 °C with ^{3}H-oestradiol-17β (5×10^{-9}M) + unlabelled oestradiol-17β (5×10^{-7}M). Note the nuclear localisation (arrows) of silver grains over myometrial cell in *a* and the lack of grains over nuclei in *b*. Stained with methylgreen-pyronin, 40-d exposure, 4-μm section, 500×.

isation was found at 0 °C at both 5 min (Fig. 1) and 2 h (not shown) in the myometrium at the extreme periphery of the section. Autoradiograms from uteri incubated at 0 °C indicated that there was little diffusion of the ^{3}H-steroid even after the 2-h incubation (Fig. 2), and thus the inner portion of the myometrium and the endometrium were unlabelled. Also at neither time was there any indication of an exclusive cytoplasmic localisation of ^{3}H-steroid. Nuclear localisation was also found at 37 °C at 5 min and 2 h (not shown). We repeated these experiments three times with ^{3}H-oestradiol and three times with ^{3}H-R2858 (Fig. 3) and obtained identical results.

Our autoradiographic localisation of a nuclear concentration of ^{3}H-E_2 and ^{3}H-R2858 after 5 min of incubation at 0 °C is in direct conflict with the earlier autoradiographic results[11]. The reason(s) the earlier workers did not see nuclear localisation is (are) unclear. Possible explanations are the differences in specific activities (earlier work 57.4 cm mmol^{-1} compared with our 89 Ci mmol^{-1}) and exposure time (in the earlier work localisation was found in 45 d with dry-mount technique while in our work the earliest localisation was found at 30 d with the thaw-mount technique, which is usually two to three times faster than the dry-mount technique).

MCF-7 cells were also incubated in MEM in the presence of different concentrations of ^{3}H-E_2 or ^{3}H-R2858 (5×10^{-11}–10^{-7}M) alone or in the presence of 100-fold unlabelled E_2 for 2 min–2 h at 0 °C and 37 °C. After incubation the MCF-7 cells were washed three times in MEM, then washed with an antibody generated against E_2 (Roussel ACE$_2$-3341 diluted 1/500 in MEM) and then spun down in 0.3 M sucrose (MEM). The use of antibody against E_2 greatly reduced background. The pellet of cells was then mounted on a stud with OCT (Tissue-Tek II), frozen in liquefied propane and processed for autoradiography.

After 2 h of incubation at 0 °C, approximately 76% of the grains were located over the nucleus (Fig. 4), whereas at 37 °C more than 90% were over nuclei. Nuclear localisation was found at 0 °C with as little as 2-min of incubation. The ratio of grains over the nucleus and cytoplasm over the concentration of ^{3}H-ligand used remained constant. However, at the lower concentrations of ligand the amount of exposure necessary to observe localisation increased that is, the quantity of observed silver grains was dose dependent). This confirms the biochemical studies of nuclear localisation of receptor at 0° C in MCF-7 cells[7].

Biochemical studies: problems with loosely trapped steroid

Autoradiograms from rat uteri exposed to ^{3}H-steroid at 0 °C for 5 min and 2 h, showed that a 5-min incubation at 2 °C would not result in the filling of 60–75% of the cytoplasmic receptors, as originally reported[11]. To resolve the discrepancy between the autoradiography in our study and the previous biochemical data, we investigated whether the binding observed previously[11] could have been the result of steroid–receptor interactions after the initial incubation period, that is during centrifugation at 225,000*g* for 1 h. In our first experiment uteri were incubated for 5 min at 0 °C with ^{3}H-E_2 (5×10^{-9}M) or ^{3}H-E_2 (5×10^{-9} M) + unlabelled E_2 (5×10^{-7} M). After 5 min the uteri were washed three times with buffer and then homogenised. In a second group, ^{3}H-E_2 (5 nM) was added to the uteri, and they were homogenised immediately (0.1 M PO_4, 0.01% monothioglycerol, 5 mM Mg and 10% glycerol, *p*H 7.4 at 0 °C). The homogenates were then spun at 105,000*g* for 1 h, and the resultant supernatants (cytosol) were withdrawn for either a hydroxyapatite assay or sucrose gradients (see below). Protein concentrations were determined by the method of Lowry[13].

For the hydroxyapatite assay[14], 200 μl of cytosol was mixed with 200 μl of hydroxyapatite suspension (1 volume dry powered DNA-grade hydroxyapatite (Bio-Rad) made up to 2 volumes with buffer). Tubes were mixed frequently for 30 min and then centrifuged for 2 min at 800*g*. The supernatant was discarded and the hydroxyapatite was washed three times with 2 ml of buffer with the same centrifugation each time. Then 1 ml of 100% ethanol was added to the hydroxyapatite and the mixture was incubated at room temperature for 1 h with frequent remixing to extract ^{3}H-steroid. Tubes were then centrifuged for 2 min at 200*g* and the supernatant was counted with 5 ml of ACS scintillation fluid (Amersham/Searle).

For the sucrose gradients, 200 μl of cytosol were layered on a density gradient of 5–30% sucrose in buffer. The gradients were centrifuged at 54,000 r.p.m. on a Beckman SW60 rotor for 16 h. Fractions of 200 μl were collected from the bottom and counted with 5 ml of ACS scintillation fluid.

In both the hydroxyapatite and the sucrose density gradient assay we obtained specific binding (8S) in cytosols from tissue which had been incubated with 5 mM ^{3}H-E_2 and in those not labelled until just before homogenisation (data not shown). Labelling with 5 nM just before homogenisation resulted in a fourfold increase over that seen in the tissue that was incubated and then washed.

In a second experiment we varied the concentration of the ^{3}H-E_2 added just before homogenisation and found that 1.25 nM added just before homogenisation was equivalent to a 5-min incubation with 5 nM. Similar results were obtained with the hydroxyapatite.

In a third experiment we prepared cytosol by centrifugation at 250,000*g* and did not add labelled steroid until just before centrifugation (that is, after homogenisation). Again we obtained as 8S peak indicating that the steroid-receptor interaction took place in the centrifuge. Therefore, ^{3}H-E_2 can bind to free receptor in the centrifuge tube. Thus, any loosely trapped steroid outside the target cells of standardly washed uteri could bind to free receptor during the tissue homogenisation and the

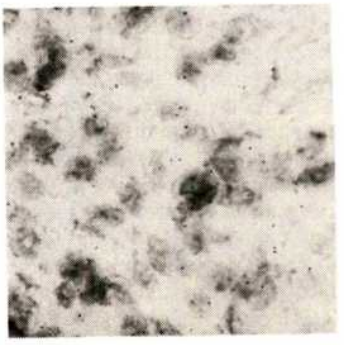

Fig. 2 Autoradiogram of rat uteri from the centre of a section incubated for 2 h at 0 °C with ^{3}H-oestradiol-17β. Note the paucity of silver grains. Stained with methylgreen-pyronin, 40-d exposure, 4-μm section, ×500.

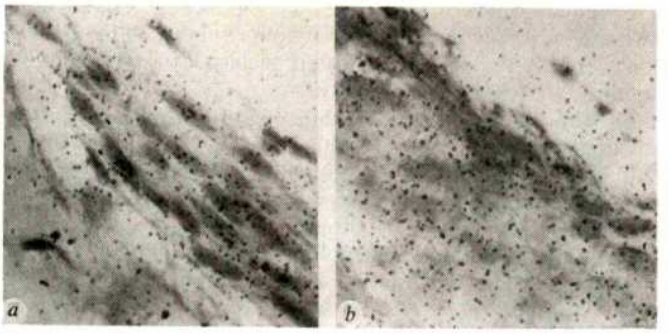

Fig. 3 Autoradiograms of rat uteri from the extreme periphery of the sections. The serosal surface is to the right in both autoradiograms. *a*, Incubated at 0 °C for 5 min with ^{3}H-R2858 (5×10^{-9}M); *b*, incubated at 0 °C with ^{3}H-R2858 (5×10^{-9}M) + unlabelled R2858 ($5\times10^{-}$7M). Stained with methylgreen-pyronin, 3.5-month exposure, 4-μm section, ×500.

preparation of cytosol in accord with the demonstration[15], with the use of cold chase experiments, that most of the binding reported earlier[11] occurred after the initial incubation period. The autoradiographic data presented here and the early biochemical data[15], together with our biochemical data therefore indicate that most of the binding of ^{3}H-E_2 to the receptor reported earlier[11] can be accounted for not in the incubation period, but during preparation of the cytosol. In addition, our autoradiographic data point to a nuclear localisation of ^{3}H-E_2 or ^{3}H-R2858 in the smooth muscle cells at the periphery of uteri incubated for 5 min at 0 °C, thus suggesting the presence of unbound nuclear receptor. The only evidence for the two-step cytoplasmic model for the intracellular translocation of steroids in the rat uterus is the observation that on homogenisation in a buffer most of the binding activity appears in the cytosol.

Equilibrium: mechanism of action of steroids

One mechanism which would explain the appearance of all binding activity in the cytosol after homogenisation of untreated uteri (when much of it was of nuclear origin *in vivo*) is a change in the free water content of the cytoplasmic compartment. That is, if the receptor were in equilibrium between the nucleus and cytoplasm, partitioned in some way according to the free water present in each compartment, homogenisation of uteri in buffer would artificially increase the water content of the non-nuclear compartment, that is, the cytosol, in agreement with the water equilibrium model[16]. To reestablish the original equilibrium much of the nuclear receptor would have to enter the cytosol. We tested this hypothesis with the following experiments.

Twenty-four uteri from 21–23-d-old Sprague–Dawley rats were homogenised at 0 °C in 3.5 ml of phosphate buffer (5 mM sodium phosphate, 0.01% mM monothioglycerol, 10% glycerol, *p*H 7.4) or Tris buffer (0.01 M Tris, 0.0015 M EDTA, 0.01% monothioglycerol, 10% glycerol, *p*H 7.4). Aliquots of the homogenate were distributed to six tubes and the following volumes of buffer were added to the tubes: 0, 0.5, 1.5, 4.5, 13.5 and 40.5 ml. The tubes were allowed to stand at 0 °C for 5 min and then centrifuged at 800*g* for 10 min. The resultant supernatants were decanted off. The first three tubes containing the supernatant were brought to a volume of 3 ml with buffer to insure an adequate volume of cytosol for the assay and all supernatants were then spun at 105,000*g* for 1 h. The resultant supernatants (cytosols) were then assayed for oestrogen receptors (see below). The nuclei from the 800*g* spin were extracted with either 3 ml of buffer or 3 ml of 0.6 M KCl in buffer for 60 min at 0 °C and then centrifuged at 800*g*. The supernatants were decanted and assayed for oestrogen receptor. For reasons that will become obvious it was considered imperative that the nuclear preparation remain as crude homogenates.

Samples of 200 μl of cytosol or KCl extract or buffer extract of nuclear pellet were incubated with 50 μl of [1,2,6,7-^{3}H]E_2 (109 Ci mol^{-1}, final concentration 5×10^{-9}) alone or with ^{3}H-E_2 + 5×10^{-7} unlabelled E_2 for 3 h at 0 °C. After incubation, the tubes were assayed by the hydroxyapatite method[14].

Figure 5 shows the effect of adding increasing volumes of buffer before separation of cytosol from the nuclear fraction (note that all values were converted to total amount of receptor in either nucleus or cytoplasm). Increasing the amount of buffer decreases the amount of receptor in the nucleus. We have repeated this experiment seven times with similar results. The shape of the curve is highly suggestive of a simple equilibrium or of a desorption of receptor from the nuclear pellet (the autoradiographic data suggest that some receptor is of nuclear origin).

We assume the following model. Nuclear receptors (R_n) are in equilibrium with cytoplasmic receptors (R_c) *in vivo*. The equilibrium may be represented by a distribution coefficient identifying the components of the partitioning of the receptors between the nucleus and the cytoplasm.

$$R_c \leftrightarrow R_n \tag{1}$$

and

$$D = \frac{R_n/V_n}{R_c/V_c} \tag{2}$$

where V_n and V_c are the nuclear and cytosol fluid volumes, respectively. Introducing $R_T = R_n + R_c$ and solving this equation for R_n yields:

$$R_n = \frac{R_T}{VcK + 1} \tag{3}$$

where

$$K = \frac{1}{DVn} \tag{4}$$

The limits of equation (3) indicate the direction of flow of the receptors between nucleus and cytoplasm. As $V_c \to 0$, $R_n \to R_T$

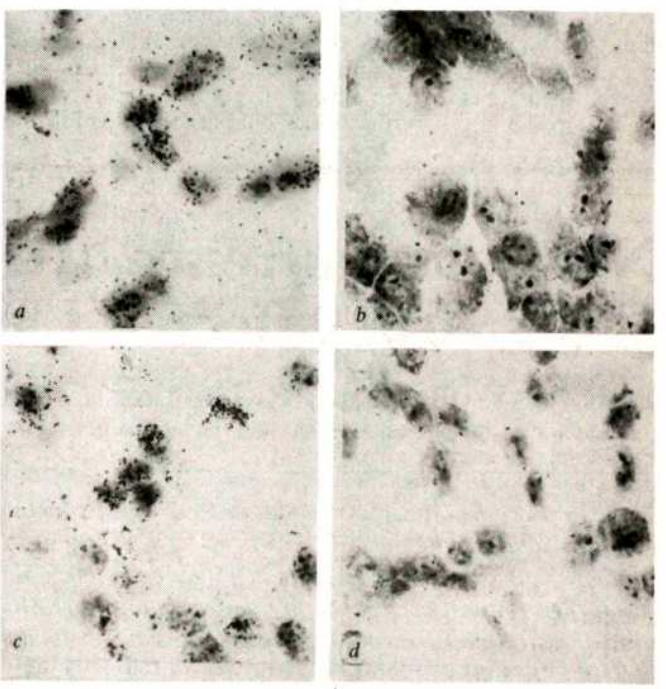

Fig. 4 Autoradiograms of MCF-7 cells. *a*, Cells incubated for 2 h with ^{3}H-oestradiol (1×10^{-9}M) at 0 °C, and *c*, at 37 °C. *b*, Cells incubated for 2 h with ^{3}H-oestradiol (1×10^{-9}M) − unlabelled oestradiol (1×10^{-7}M) at 0 °C, and *d* at 37 °C. The predominant localisation is nuclear at both 0 °C and 37 °C. The large black dots seen in the nuclei of unlabelled cells (*b* and *d*) are nucleoli. Stained with methylgreen-pyronin, 2-week exposure, 4-μm sections, ×900.

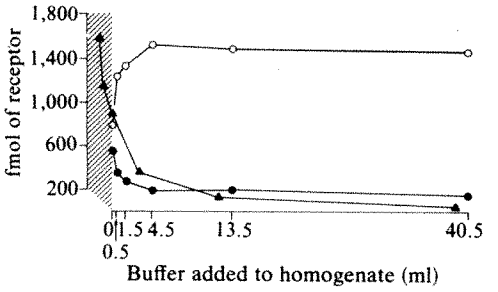

Fig. 5 Amount of apparent nuclear receptor (●), and amount of apparent cytoplasmic receptor (○) plotted as a function of volume of buffer added to homogenate. At 0 added volume the slope of the curve is quite steep. The theoretical values for nuclear receptor that would be obtained if $R_T - 1{,}588$ fmol and $K = 0.75$ in equation (3) are plotted as a function of the cytosolic volume (V_c) (▲). Because we can never approach $V_c = 0$ or the *in situ* volume of the cytoplasm experimentally, we have moved the x-axis to the right an arbitrary amount and put this part of the theoretical curve under cross-hatching.

(*in vivo*) and as $V_c \to \infty$, $R_n \to 0$ (in typical *in vitro* experiments in which large volumes of buffer are used for homogenisation). R_n is measured as c.p.m. in the nuclear pellet and V_c is the total added volume of the homogenate. In Fig. 5 we plot R_n and R_c as a function of V_c. The third plot in Fig. 5 contains points calculated from equation (3) with $K = 0.75$.

For the immature rat uterus, the distribution constant is high. We expect that this constant will vary with different steroids and different tissues. This model provides for the first time a mechanism for the translocation of cytoplasmic (*in vivo*) or cytosolic (*in vitro*) receptor to the nucleus (no mechanism has been found which is compatible with the two-step cytoplasmic model[17]).

In this scheme, free steroids enter both the cytoplasm and the nucleus of a target cell and bind to unoccupied receptors. *In vivo* or *in vitro* at 37 °C, the receptors are activated *in situ* and the nuclear fraction of steroid–receptor complexes binds to chromatin and thus precipitates out of solution (that is, one has to extract with KCl to get them back in solution). The nuclear volume then appears to be devoid of receptors and receptors move into the nucleus from the cytoplasm to reestablish the initial equilibrium (translocation). This model agrees very well with the published data, and in fact the equilibrium model was considered in the past but rejected because of the inability to demonstrate free nuclear receptor[18].

As with many of the biochemical studies dealing with the location of unbound steroid receptors[15], our data are subject to different interpretations. Alternative explanations for the results of our dilution experiments are (1) that the initial homogenisation of the tissue in hypotonic buffer caused swelling of the nuclei and an initial shift of cytoplasmic receptor into the nuclear compartment and that subsequent dilutions just redistributed the receptor back into the cytoplasmic compartment, or (2) that the increased nuclear receptor with a concentrated homogenate is due to nonspecific adsorption of cytoplasmic receptor to the nuclei. While we feel that both these explanations are possible, we consider them improbable. We feel that of all previously used techniques, autoradiography is the least susceptible to redistribution artefacts. The autoradiographic data presented here for the uterus suggest that there are bound nuclear receptors at 0–4 °C which appear in the cytoplasmic compartment on homogenisation[15].

Natural occurrence of 2-5A in interferon-treated EMC virus-infected L cells

B. R. G. Williams, R. R. Golgher*, R. E. Brown, C. S. Gilbert & I. M. Kerr

National Institute for Medical Research, Mill Hill, London NW7, UK

Until now the interferon-mediated 2′–5′ adenine oligonucleotide inhibitors (2–5A) of cell-free protein synthesis have not been detected in intact cells. Here we report their natural occurrence in interferon-treated, EMC virus-infected mouse L cells in amounts consistent with the idea that they play a part in the inhibition of virus growth.

SOME years ago we demonstrated an interferon-mediated inhibition of cell-free protein synthesis in extracts prepared from interferon-treated, virus-infected cells[1,2]. Subsequently we reported that protein synthesis in cell-free systems from interferon-treated cells shows an enhanced sensitivity to inhibition by double-stranded RNA (dsRNA)[3]. On the basis of these observations and the known effects of dsRNA in the intact cell and cell-free system[4–6], we suggested[3] that the production of viral dsRNA in response to infection (even with a DNA virus[7]) could bring about a general inhibition of protein synthesis in interferon-treated cells such as is indeed observed, for example, in interferon-treated, vaccinia virus-infected mouse L cells[8,9]. The cell dies but little virus is produced: an effective way of limiting a natural infection. Alternatively, the triggering by dsRNA of a more transient or selective inhibition could result in the degradation of viral nucleic acid but allow the ultimate recovery of the cell. The enhanced sensitivity of cell-free protein

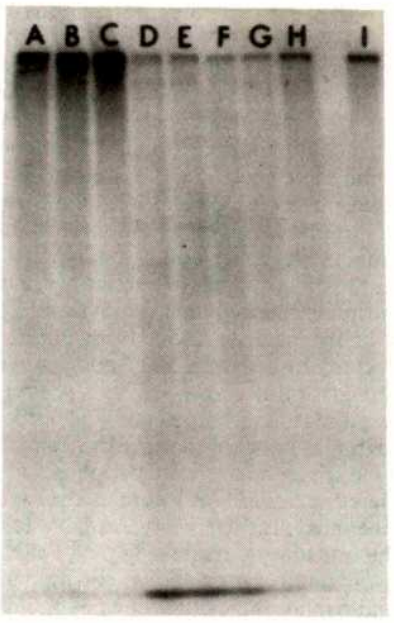

Fig. 1 Recovery of 2-5A from intact cells. 2-5A was assayed by its ability to activate a nuclease and cause the degradation of added ^{32}P-RNA in rabbit reticulocyte lysates[23]. Autoradiographs of SDS polyacrylamide gel analyses of the ^{32}P-RNA are shown. Comparison of 2-5A activity isolated from control (A), EMC infected (B), interferon-treated (C) and interferon-treated, EMC virus-infected (D–H) cells at overall dilutions of 6 (A–D) and 18, 54, 162 and 486 (E–H) fold, respectively. I, control (no inhibitor). In typical assays of this type using standard preparations of 2-5A, nuclease activity is clearly detectable down to a final concentration of $\leq 2.4 \times 10^{-9}$ M (Fig. 3*a*, tracks 19–23). Mouse L cells (300 ml, 0.75×10^6 cells per ml) were treated for 17 h at 37°C with 400 reference units (20 effective units) per ml of partially purified (5×10^7 reference units per mg of protein) mouse interferon, infected with 20 PFU per cell of EMC virus and incubated for 4 h at 37 °C. Control cells with or without interferon treatment or EMC infection were incubated in parallel. Cells were collected and washed, packed cells were lysed into an equal volume of 0.5% NP40 in 10 mM HEPES buffer, *p*H 7.5, 90 mM KCl, 1.5 mM magnesium acetate. The 100,000*g* supernatant fractions (500 μl) were heated to 95 °C for 5 min, centrifuged to remove denatured protein and the supernatants fractionated on DEAE Sephadex[28]. Fractions corresponding to 2-5A were eluted with 1 M NH_4HCO_3, lyophilised extensively to remove bicarbonate and redissolved in 20 μl of H_2O before assay. In the nuclease assays here and in Figs 2 and 3, 30–300 ng (equivalent to 3,000–5,000 c.p.m. at a specific activity of 10^4–10^5 c.p.m. per μg) of ^{32}P-labelled polyadenylated mRNA (ref. 20) or 28S rRNA from Ehrlich ascites tumour cells were added per 12.5-μl assay. (Identical results were obtained throughout with the two types of RNA.)

synthesis to dsRNA showed the same interferon dose–response curve as did the antiviral effect in the intact cell, indicating that the two effects might indeed be closely related[3]. The basis for the effect of dsRNA was, therefore, investigated.

In the cell-free system two distinct mechanisms seem to be involved: (1) phosphorylation of the protein synthesis initiation factor eIF2 by an interferon and dsRNA mediated kinase; and (2) degradation of mRNA by a nuclease(s) activated by sub-nanomolar levels of an unusual oligonucleotide pppA2′p5′A2′p5′A (and related oligomers collectively referred to as 2-5A) synthesised by an interferon and dsRNA-mediated synthetase[10–18]. In intact cells, 2-5A, when artificially introduced, has also been shown to be effective in the activation of a nuclease(s) and consequent inhibition of protein synthesis and virus growth[19–21]. Both in the cell-free system and when introduced into intact cells 2-5A is unstable and in the absence of a 2-5A regenerating system the activation of the nuclease and inhibition of protein synthesis are transient[18,20–22]. All of these results are consistent with a possible role for 2-5A in the inhibition of virus replication in the interferon-treated cell, but they do not provide direct evidence for it. More particularly, there has been no direct evidence for the natural occurrence of 2-5A, which has only been detected after synthesis in crude cell extracts or with the partially-purified synthetase. It has remained possible, therefore, that it is an artefact of cell-free systems. We recently reported that 2-5A deliberately introduced into cells can be recovered from them[20]. Using the same methods for the recovery of 2-5A here we report its natural occurrence in interferon-treated, encephalomyocarditis (EMC) virus-infected cells in amounts consistent with the idea that it plays a part in the inhibition of virus growth in these cells.

Presence of 2-5A in extracts from interferon-treated, EMC virus-infected L cells

Extracts were prepared from interferon-treated and control cells 4 h postinfection with EMC virus and centrifuged at 2,000 or 100,000*g*. The supernatant fractions were either precipitated with trichloroacetic acid (TCA, for the 2,000*g* supernatant) or heated to 95 °C for 5 min (for the 100,000*g*), centrifuged to remove denatured protein and purified on DEAE Sephadex to remove the majority of contaminating mono- and oligonucleotides.

The fractions corresponding to the position at which 2-5A would have been expected to elute were pooled, lyophilised, redissolved in a small volume and assayed for 2-5A. Two types of assay were used: activation of a nuclease in the rabbit reticulocyte lysate and inhibition of protein synthesis in EMC RNA-programmed cell-free systems from Ehrlich ascites tumour (EAT) cells[23]. In the first of these (Fig. 1A) ^{32}P-labelled mRNA was incubated in a rabbit reticulocyte lysate in the presence or absence of added test material. Whereas the addition of material from control cells plus or minus EMC infection or from interferon-treated cells was without significant effect (Fig. 1, A–C respectively), that from interferon-treated, EMC virus-infected cells showed evidence for activation of a nuclease(s) over a range of dilutions from 6 to 486-fold (Fig. 1, D–H). In accord with this, of these extracts, only that from interferon-treated, EMC virus-infected cells also inhibited protein synthesis at similar dilutions in the cell-free system. In an additional control experiment an extract from such cells, but not from a mixture of equal volumes of interferon-treated cells and EMC virus-infected cells, was similarly effective in activating a nuclease in the reticulocyte system. In this latter experiment the interferon-treated, EMC vius-infected cells and the mixture (interferon-treated cells plus EMC-infected cells) were each lysed with NP40 on ice and immediately precipitated with TCA. This was done to exclude the formal possibility that any 2-5A detected could have been synthesised during the processing of the extracts. (In fact, the extract prepared from the interferon-treated, EMC virus-infected cells in the latter more rapid fashion contained if anything slightly greater activity than did

Table 1 Trimer and tetramer triphosphate components of 2-5A recovered from HPLC of an extract from interferon-treated, EMC virus-infected L cells assayed by inhibition of cell-free protein synthesis

Dilution into the cell-free system	^{14}C-amino acid incorporation in the presence of dialysed and concentrated HPLC fractions (c.p.m. per 10 μl)*	
	25–29 (putative trimer, triphosphate)	35–39 (putative tetramer, triphosphate)
62.5	3,700	4,900
125	6,250	5,714
375	7,830	7,800
1,250	14,250	14,316
3,750	16,480	16,500

Pooled fractions 25–29 (750 μl) and 35–39 (750 μl) from the HPLC analysis of the interferon-treated, EMC virus-infected cell material shown in Fig. 2*b* were each dialysed against four changes of 100 volumes of H_2O at 4 °C, lyophilised, redissolved in 20 μl of H_2O and assayed in an EMC RNA-programmed EAT cell-free system as described in Fig. 4. Standard trimer and tetramer preparations (750 μl of 1 μM in 0.2 M ammonium phosphate, *p*H 7.0) processed in parallel were each recovered in 80% yield. Non-phosphorylated A2′p5′A2′p5′A (1 μM) was added as 'carrier' before dialysis: parallel controls confirmed that it was without effect in the cell-free system.

* Incorporation in the absence of added inhibitor was 17,100.

those prepared by the longer method involving the initial isolation of a 100,000*g* supernatant.) The material in the interferon-treated, infected cell extract responsible for the activation of the nuclease in the reticulocyte lysate was sensitive to digestion with bacterial alkaline phosphatase and snake venom phosphodiesterase, but resistant to digestion with T2 and micrococcal nucleases, as would be expected for 2-5A[24]. Further evidence for the identity of this material as 2-5A came from its performance on HPLC in comparison with appropriate standards.

Characterisation of 2-5A by HPLC and comparison of the relative activities of the trimer and tetramer in the rabbit reticulocyte and EAT cell-free systems

2-5A synthesised with the synthetase from interferon-treated mouse L cells or rabbit reticulocytes consists of a mixture of oligonucleotides of the general formula ppp(A2′p)$_n$A with the trimer as the predominant species[12,25]. The individual components, trimer, tetramer and pentamer ($n = 2$–4, respectively) were isolated by chromatography on DEAE cellulose[25] and subjected to HPLC. In Fig. 2*a* the pattern obtained with a recombined mixture of these standard preparations is presented. Peaks 7 to 9 correspond to the trimer, tetramer and pentamer triphosphates, respectively. All preparations also contain smaller and variable amounts of the corresponding di- and monophosphates (peaks 4–6 and 1–3, respectively)[25]. These are thought to represent breakdown products of the predominant triphosphates. (The terms trimer, tetramer and pentamer will be used to denote preparations of this type consisting largely of the triphosphates, but also containing smaller amounts of the di- and monophosphates. The more complete nomenclature, for example trimer triphosphate, will be used to identify the individual species.) It has previously been shown that the trimer diphosphate (but not the monophosphate) has essentially the same specific biological activity as the corresponding triphosphate (ref. 25 and L. A. Ball, personal communication). As will be seen below, the same seems to be true for the corresponding tetramer and pentamer species. It is not known whether the diphosphates are active *per se* or are simply efficiently rephosphorylated in the assay systems used.

An analysis of the putative 2-5A from interferon-treated, EMC virus-infected cells (to which ATP and p$_4$A were added as optical density markers) is shown in Fig. 2*b*. Predictably, too little 2-5A was present for it to be clearly identified by optical density (although it is possible that peaks X and Y do indeed correspond to the trimer and tetramer triphosphates). Accordingly, appropriate fractions (1–53) were analysed for biological activity using the most sensitive assay available to us; nuclease activation in the reticulocyte lysate (Fig. 2*c*). Peaks of nuclease activity were obtained in positions corresponding to the tetramer di- and triphosphates (fractions 6–8 and 35–41) and the pentamer di- and triphosphates (fractions 11–13 and 45–47).

The apparent absence of trimer in the above preparation was curious but the explanation for it became clear from an analysis of the activity of appropriate standards. It seems that the trimer tri- and diphosphates (whether chemically or enzymically synthesised) are relatively poor activators of the nuclease and inhibitors of protein synthesis in rabbit reticulocyte lysates,

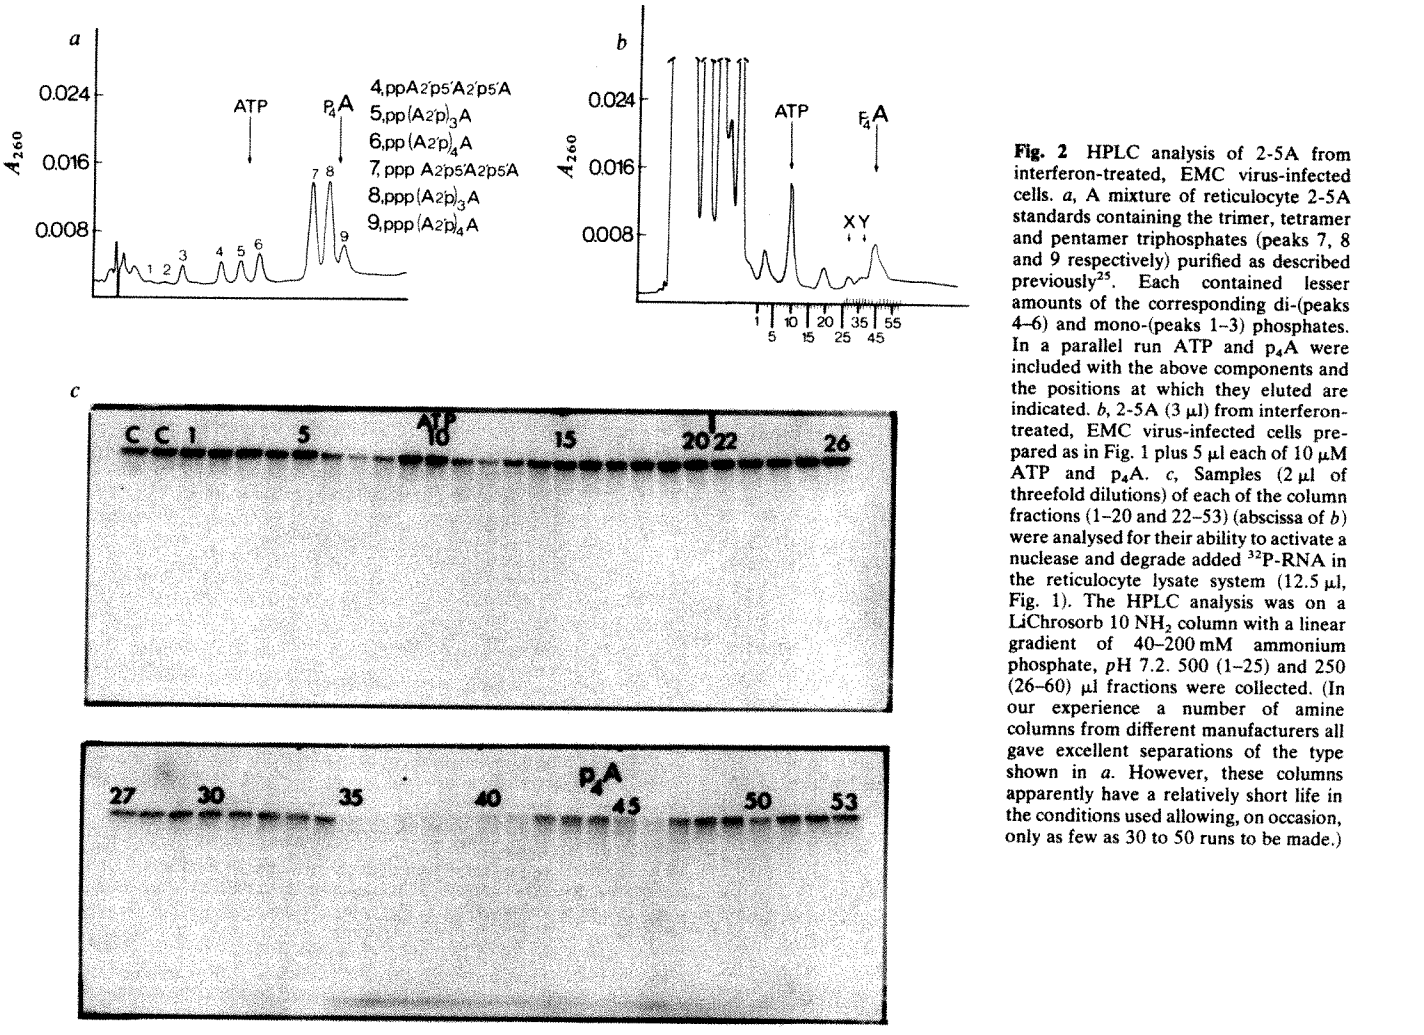

Fig. 2 HPLC analysis of 2-5A from interferon-treated, EMC virus-infected cells. *a*, A mixture of reticulocyte 2-5A standards containing the trimer, tetramer and pentamer triphosphates (peaks 7, 8 and 9 respectively) purified as described previously[25]. Each contained lesser amounts of the corresponding di-(peaks 4–6) and mono-(peaks 1–3) phosphates. In a parallel run ATP and p$_4$A were included with the above components and the positions at which they eluted are indicated. *b*, 2-5A (3 μl) from interferon-treated, EMC virus-infected cells prepared as in Fig. 1 plus 5 μl each of 10 μM ATP and p$_4$A. *c*, Samples (2 μl of threefold dilutions) of each of the column fractions (1–20 and 22–53) (abscissa of *b*) were analysed for their ability to activate a nuclease and degrade added ^{32}P-RNA in the reticulocyte lysate system (12.5 μl, Fig. 1). The HPLC analysis was on a LiChrosorb 10 NH$_2$ column with a linear gradient of 40–200 mM ammonium phosphate, *p*H 7.2. 500 (1–25) and 250 (26–60) μl fractions were collected. (In our experience a number of amine columns from different manufacturers all gave excellent separations of the type shown in *a*. However, these columns apparently have a relatively short life in the conditions used allowing, on occasion, only as few as 30 to 50 runs to be made.)

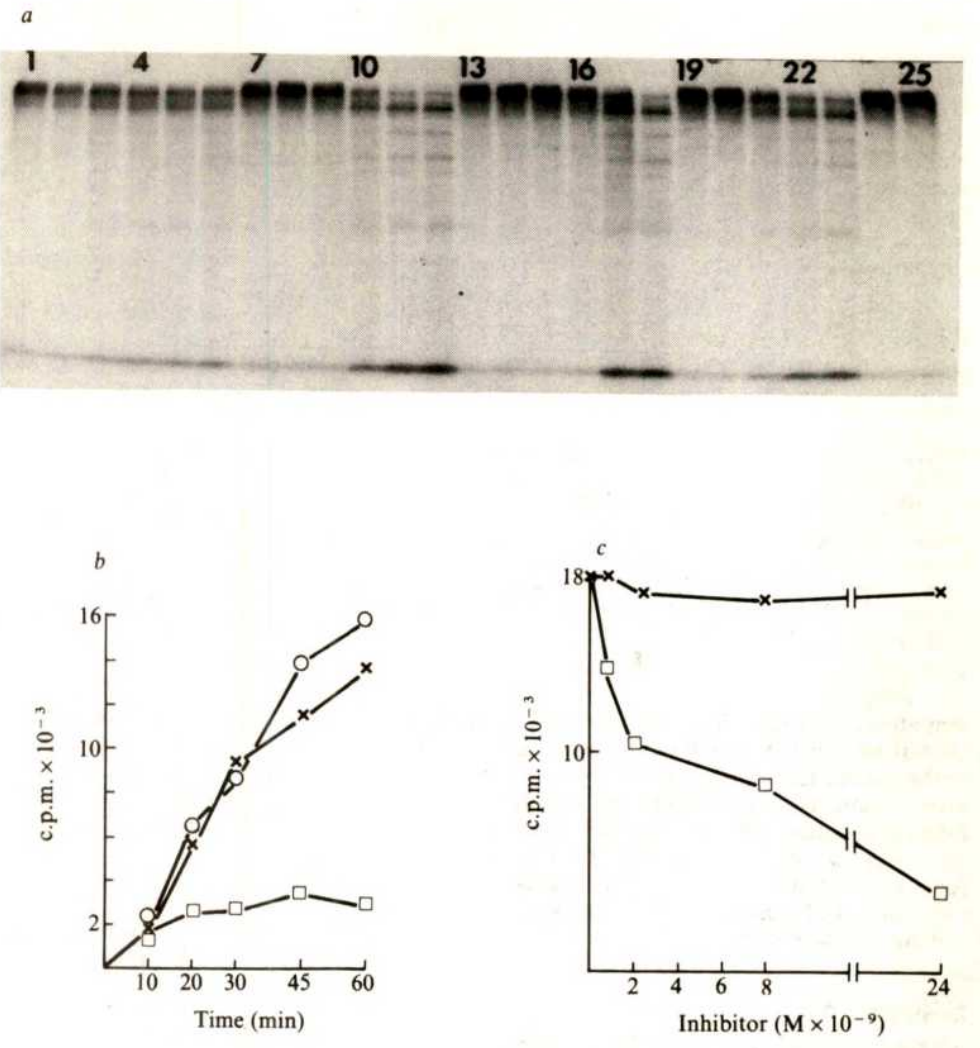

Fig. 3 Comparison of the activities of the trimer, tetramer and pentamer components of reticulocyte 2-5A in the reticulocyte lysate system. *a*, Activation of a nuclease. Tracks 1–6: 2.4, 8, 24, 80, 240 and 800×10^{-9} M trimer. Tracks 7–12 and 13–18: O.024, 0.08, 0.24, 0.8, 2.4 and 24×10^{-9} M tetramer and pentamer respectively. Tracks 19–23: 0.24, 0.8, 2.4, 8 and 24×10^{-9} M 2-5A (unfractionated). Tracks 24 and 25: no inhibitor controls. Assays were carried out as described in Fig. 1. *b*, *c*, Inhibition of ^{35}S-methionine incorporation in micrococcal nuclease treated rabbit reticulocyte lysate systems[29] programmed with EMC RNA[23]. *b*, Time course of incorporation in the absence (○) and presence of 8×10^{-9} M trimer (×) and tetramer (□). *c*, Inhibitory activity of different concentrations (abscissa) of trimer (×) and tetramer (□). The ordinates give the ^{35}S-methionine incorporated (c.p.m. per 10-μl sample) into acid insoluble polypeptide with time of incubation at 30 °C (abscissa) in (*b*) and at 60 min in (*c*). The reticulocyte, trimer, tetramer and pentamer preparations were those analysed in Fig. 2*a*. The concentrations of these and of the unfractionated preparation of 2–5 A are given in AMP equivalents. (1 ml of 1 mM inhibitor was taken to have an absorbance of 15 at 260 nm measured in a 1 cm pathlength cell.)

although apparently fully active in this respect in other systems (refs 12 and 25 and Fig. 4 below). The relative activities of the trimer, tetramer and pentamer in the activation of a nuclease in the reticulocyte lysate are compared in Fig. 3*a*. The tetramer and pentamer are both capable of clear-cut activation of a nuclease at final concentrations of 10^{-9} M. (The concentrations of the different species of 2-5A are given in AMP equivalents throughout.) Indeed, with fresh preparations of high specific activity RNA requiring the addition of smaller amounts of RNA, activation of nuclease can be detected with as little as 0.024×10^{-9} M of these components in this type of assay. Significantly, higher concentrations of the trimer are required ($>8 \times 10^{-9}$ M) and, more importantly, even with these higher concentrations the activation of the nuclease seems to be very much less efficient (Fig 3*a*, tracks 1–6). In accord with this, 0.8 and 8×10^{-9} M tetramer (□) were sufficient to give detectable and substantial inhibitions respectively of amino acid incorporation in an EMC RNA-programmed reticulocyte lysate, whereas similar or greater concentrations of trimer (×) were without effect (Fig. 3*b*, *c*). In contrast the trimer (×) and tetramer (□) appeared almost equally effective in activating nuclease(s) (Fig. 4*a*, *b*) or inhibiting EMC RNA-programmed protein synthesis (Fig. 4*c*) in the EAT cell-free system.

The basis for the ineffectiveness of the trimer in the reticulocyte cell-free system is not known. It does not seem to be the result of a more rapid degradation of this component in this system and most probably, therefore, reflects a preference of the activatable nuclease for the tetramer or higher oligomers. Whatever the explanation, it is clear that the failure to detect trimer in the HPLC analysis of the 2-5A present in the interferon-treated, EMC virus-infected cell extracts described in Fig. 2*b* could simply have reflected the choice of the reticulocyte as the assay system. This was shown to be the case by assaying appropriate fractions from the HPLC analysis (Fig. 2*b*) for the ability to activate a nuclease and inhibit protein synthesis in the EAT system. In a nuclease assay measuring conversion of ^{3}H-labelled VSV mRNA to acid solubles of the type shown in Fig. 4*a*, *b*, peaks were obtained in fractions 1 (corresponding to the trimer diphosphate), 7 (tetramer diphosphate), 26–28 (trimer triphosphate) and 36–38 (tetramer triphosphate), the results being consistent with there being, if anything, slightly more trimer than tetramer present (data not presented). The slightly lower sensitivity of the ^{14}C-labelled amino acid incorporation assay combined more importantly with its higher sensitivity to the 'non-specific' inhibitory effects of the salt gradient used in the elution from HPLC, made it impossible to detect convincingly even the triphosphorylated trimer and tetramer peaks by direct analysis of the column fractions in this type of assay. They were readily detected, however, in apparently identical amounts when appropriate column fractions were pooled, dialysed, concentrated and analysed in such systems (Table 1).

It can be concluded, therefore, that the triphosphorylated trimer, tetramer and pentamer components at least of 2-5A are present in interferon-treated mouse L cells 4 h postinfection with 20 plaque forming units (PFU) per cell of EMC virus. It is possible that smaller amounts of the diphosphates are also present in the intact cell, but it seems probable that these reflect partial breakdown products of the corresponding triphosphates. If higher oligomers are present they are not detectable with the

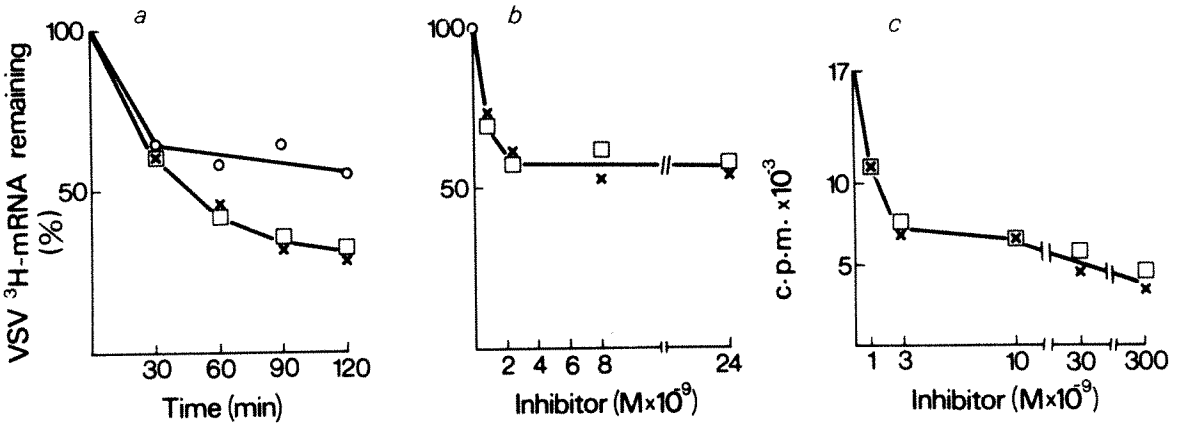

Fig. 4 Comparison of the activities of the trimer and tetramer components of reticulocyte 2-5A in EAT cell-free systems. *a*, *b*, Activation of a nuclease. Breakdown of VSV ^{3}H-mRNA on incubation in an EAT cell-free system: *a*, alone (○) or with 8×10^{-9} M trimer (×) or tetramer (□) or, *b*, with different concentrations (abscissa) of trimer (×) or tetramer (□). VSV ^{3}H-mRNA (4×10^5 c.p.m. per μg) was added to a final concentration of 2 μg ml^{-1} and incubated in identical conditions to those previously described for L cell-free systems[18] at 30 °C for the times indicated in (*a*) and 120 min in (*b*). The ordinates give the residual acid insoluble radioactivity as a percentage of the zero time value (2,600 c.p.m. per 4-μl sample) in (*a*) and of the 120-min control (no inhibitor) value (3,500 c.p.m. per 10-μl sample) in (*b*). (The 100% point in (*b*) corresponds to the 120 min control (○) point in (*a*).) *c*, Inhibition of amino acid incorporation by different concentrations (abscissa) of the trimer (×) and tetramer (□) in an EMC RNA-programmed EAT cell-free system prepared and incubated for 120 min at 30 °C as described for similar systems from mouse L cells[18,30]. The ordinate gives the incorporation of a mixture of ^{14}C-amino acids into acid insoluble polypeptide (c.p.m. per 10-μl sample). The trimer and tetramer preparations were the same as those used in Figs 2*a* and 3. Their concentrations are given in AMP equivalents as described in Fig. 1.

procedures used here. The heterogeneity in the length of the 2-5A synthesised in cell extracts has been one of the odd aspects of the system for which as yet there is no explanation. This, perhaps more than anything else, emphasised the possibility that 2-5A, in the form isolated, might be no more than an intriguing artifact of cell-free systems. The discovery of similar heterogeneity here in the intact cell argues against this and, although providing no explanation for the phenomenon, suggests that it may have some significance.

Discussion

We have previously shown that 2-5A artificially introduced into cells is capable of activating a nuclease(s) and inhibiting protein synthesis and virus growth[19–21]. Here we have demonstrated the natural occurrence of 2-5A in amounts sufficient for it to be responsible for a similar sequence of events in interferon-treated, EMC virus-infected L cells. Assuming 50% recovery of the 2-5A throughout the isolation procedure (which seems reasonable from appropriate control experiments), the yields obtained in the four experiments completed have been consistent with concentrations of $20–200 \times 10^{-9}$ M 2-5A in the interferon-treated, EMC virus-infected cells from which the extracts were made. Preliminary evidence has also been obtained for an enhanced rate of breakdown of preformed RNA in these cells consistent with the activation of a nuclease (unpublished data). The relative importance of this mechanism, however, compared with any effect of the interferon and dsRNA mediated kinase, or alternative mechanism(s) not mediated through dsRNA, in this and other interferon-treated, virus-infected cell systems remains to be established.

Here we have detected 2-5A only in the extracts from interferon-treated, virus-infected cells, whereas the wide distribution and variation in amount of the synthetase has raised the possibility that it may have a wider significance in the regulation of cell growth or development[26]. The possible wider significance of the synthetase has been further emphasised by the recent demonstration by Ball that an enzyme which is almost certainly the 2-5A synthetase is capable (in cell extracts) of adding AMP in 2′-5′ linkage to a variety of important metabolites such as NAD, ADP ribose and AppppA (ref. 27). On the other hand, were 2-5A to have been present in physiological concentrations of less than 10×10^{-9} M in any of the above cells we would not have detected it with the procedures used. Clearly, a more sensitive and convenient assay for 2-5A and a much more detailed analysis of this and alternative systems will be required before the full significance of either 2-5A or its synthetase can be assessed. Meanwhile, however, it is unlikely from the results presented here that 2-5A is a mere artefact of the cell-free system and it is reasonable to assume that it plays some part in the inhibition of virus growth in the interferon-treated, EMC virus-infected cell.

We thank S. S. Jones and C. B. Reese for the gift of chemically synthesised pppA2′p5′A2′p5′A and related oligonucleotides and W. T. Collins and G. Johnstone of Waters Associates for initial help with the HPLC. R.R.G. was supported by a fellowship from the Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, Brazil.

Observations of a flaring X-ray pulsar in Dorado

E. P. Mazets, S. V. Golenetskii, V. N. Il'inskii, R. L. Aptekar' & Yu. A. Guryan

A. F. Ioffe Physico-Technical Institute, Leningrad, 194021, USSR

The γ-ray burst detector Konus[1], on the Venera 11 and Venera 12 spacecraft, detected on 5 and 6 March, 1979 two bursts of hard X rays originating from the same source. These events are quite unusual and of considerable interest. The burst of 5 March was very intense, particularly in the initial phase. This event was also observed by several other spacecraft[2]. The second burst on 6 March was considerably weaker. The observations reported here permitted us to obtain a detailed time structure of the bursts, to measure their energy spectra and to locate the source on the celestial sphere.

Figure 1 displays the time structure of the initial phase of the 5 March burst recorded on Venera 11 in the energy range 50–150 keV with a time resolution of 1/64 s. Note that all results obtained on Venera 11 and Venera 12 coincide completely. The burst has a very sharp onset. The initial, narrow structureless pulse is characterised by a very short rise time, ~15 ms, and a longer decay, ~150 ms. The peak count rate in the 50 cm^2 sensor attains 4×10^5 c.p.s. This means that during a short time (~0.1 s), the flux of hard X rays exceeded the diffuse cosmic background by a factor of 10^4. The time structure of the burst measured with resolutions of 1/4 and 1 s is shown in Fig. 2*a*, *b*. An analysis of these data clearly indicates that the radiation observed is that of an X-ray pulsar with a period 8.1 ± 0.1 s (ref. 3). The pulsed radiation is seen to exhibit a train of stronger pulses and another train of interpulses with a relative phase of 0.5. The level of intensity in the deep minima between the pulses apparently reflects a slowly varying component of radiation.

The most remarkable fact here is that the onset of radiation is almost instantaneous with a subsequent fast decay. The standard length of measurements (66 s) was found to be insufficient for this event; however, measurements carried out 6 min after the beginning of the burst revealed that by this time the intensity of radiation had decreased to background level.

Eight consecutive measurements of the energy spectra were carried out, each of 4 s duration. Only the first spectrum measured in the initial burst phase differs in shape from the others. Therefore, Fig. 3 presents the energy spectrum of the burst for the first time interval, 0–4 s (histogram *a*), and a spectrum averaged over the interval 4–32 s (histogram *b*). The energy spectra of this event differ from those of most of the γ-bursts[4]. The shape of the pulsed radiation spectrum is more similar to those of the spectra of continuously emitting X-ray sources, such as Cyg X−1, than to the substantially harder spectra of typical γ bursts. It may be approximated by the relationship $E^{-1}\exp(-E/kT)$, with $kT=30$ keV.

The spectrum of the initial burst phase has a harder tail, which is possibly associated with radiation of only the initial pulse. The spectral feature in the region 400–500 keV is a remarkable characteristic of this spectrum. The total identity of the spectra obtained on Venera 11 and Venera 12 completely eliminates the possibility that this feature is a result of random fluctuations. A more detailed analysis of the spectrum shows that the observed feature may be associated with the presence of a broad line at 430 keV with a FWHM of 30–40%. It is difficult to suggest an unambiguous explanation of the nature of this radiation component. Note, however, that 430 keV corresponds to the energy of the 511-keV annihilation line which has undergone a redshift of $(1-2GM/c^2R)^{1/2}$ in the gravitational field of a compact object with $M=1M_\odot$ and $R=10^6$ cm.

The average pulsed radiation flux with $E_\gamma>30$ keV is 1×10^{-5} erg cm^{-2} s^{-1}. At the peak of the initial pulse the flux is 1.5×10^{-3} erg cm^{-2} s^{-1}. Evaluation of the flux in the line with $E_\gamma\approx430$ keV yields 3×10^{-6} erg cm^{-2} s^{-1}, or, assuming the line radiation to be emitted only in the initial pulse, 5×10^{-5} erg cm^{-2} s^{-1}.

The location of this flaring X-ray pulsar, designated earlier FXP 0520−66 (ref. 3), is shown in Fig. 4. The readings of the Konus sensor unit with anisotropic angular sensitivity yield a fairly large error box with sides of about 3°. Intersection of this region with a narrow annulus obtained from the time-of-arrival difference between Venera 11 and Venera 12 gives the final box as a narrow annular band 4′ wide. Based on the latest spacecraft trajectory data, the position of this annulus on the celestial sphere is defined by the angular radius $68.528\pm0.030°$ with the centre at $\alpha=44.427°$, $\delta=-2.747°$ (1950.0). This position is in good agreement with other data. The arc of radius 68.528° passes 1.7 arc min to the south-east of the centre of the error box for this source given in ref. 2 − α = 5 h 25.92 min, $\delta=-66.122°$.

As mentioned above, the observed source was found to be recurrent. On the next day, 6 March, the Konus detector on both spacecraft recorded, after the same time interval $\Delta t=$ 14 h 25 min 46.15 s a short burst ~1.5 s long with the same soft

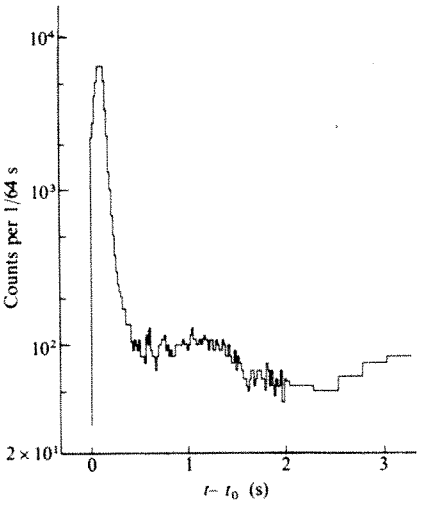

Fig. 1 Initial stage of the 5 March event as recorded on Venera 11. The data of Venera 12 are identical. Energy range covered 50–150 keV. Time resolution, 1/64 s. Burst onset time t_0. Venera 11: 15 h 51 min 39 s, 145 UT. Venera 12: 15 h 51 min 44 s, 350 UT.

spectrum (Fig. 3, histogram *c*). Its intensity, however, was 100 times lower. Its time structure is shown in Fig. 2*c*, *d*, with results of source location determination presented in Fig. 4. For the 6 March event, the process responsible for the emission in the source was evidently weaker and longer than in the case of the 5 March burst. We can assume that the decaying pulsed radiation could have been accordingly weaker and, hence, not observable against the background present.

The most plausible model for the FXP0520−66 source seems to be a binary system containing a neutron star. The separation between the components should be sufficiently large to reduce the accretion rate to the level where there would be no observable radiation in the steady state. The neutron star should possess a strong magnetic field; indeed, the presence of two pulse trains in the burst implies that during accretion the plasma moves along the field lines with the emitting regions located near the magnetic poles. The origin of the non-stationary accretion resulting in a burst remains unclear. The characteristic rise time to almost full peak luminosity is small, less than 15 ms, implying that processes associated with the neutron star proper, such as the development of instabilities in the magnetosphere, should play the part of the trigger mechanism.

The observed source projects on to the Large Magellanic Cloud. Moreover, it lies close in position to the supernova remnant N49 in the Large Magellanic Cloud[2]. However, its energetics suggest that it is not only located in our Galaxy, but even comparatively close to the Sun. Indeed, if the source were at 55 kpc the luminosity of isotropic radiation in the initial impulse would be $\sim 5\times10^{44}$ erg s^{-1}, and that at the pulsating stage, $\sim 3.6\times10^{42}$ erg s^{-1}. Accordingly, the energy released in the initial impulse would be $\sim 1.2\times10^{44}$ erg, that at pulsating stage (lasting $\sim$100 s) $\sim 3.6\times10^{44}$ erg, and in line radiation, $\sim 10^{42}$ erg. The total energy in the event would then be $>4.6\times10^{44}$ erg. The shape of pulsations (Fig. 2) shows that the angular pattern of emission cannot be very narrow. Taking into account possible directivity of emission could not reduce these estimates by more than a factor of 10. Such large figures for the total energy and luminosity apparently rule out the possibility that this source is located in the Large Magellanic Cloud. On the other hand, if its average luminosity in the pulsating phase is close to that of X-ray sources in binaries (10^{37}–10^{38} erg s^{-1}), an estimated distance to it is 100–300 pc.

Consider some implications of the assumption on the galactic nature of this unusual X-ray pulsar. In its characteristics, mainly in the time scale of its variability and the presence of an impulsive initial stage, the FXP0520−66 source differs

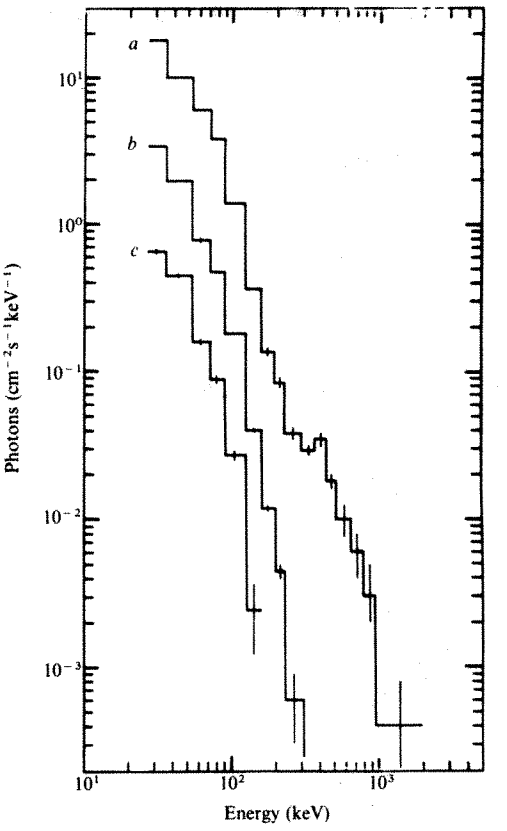

Fig. 3 Burst energy spectra. *a*, 5 March, spectrum of initial stage for the first 4 s; *b*, 5 March, averaged spectrum of pulsed radiation; *c*, spectrum of 6 March burst. Data from Venera 11 and Venera 12 are identical.

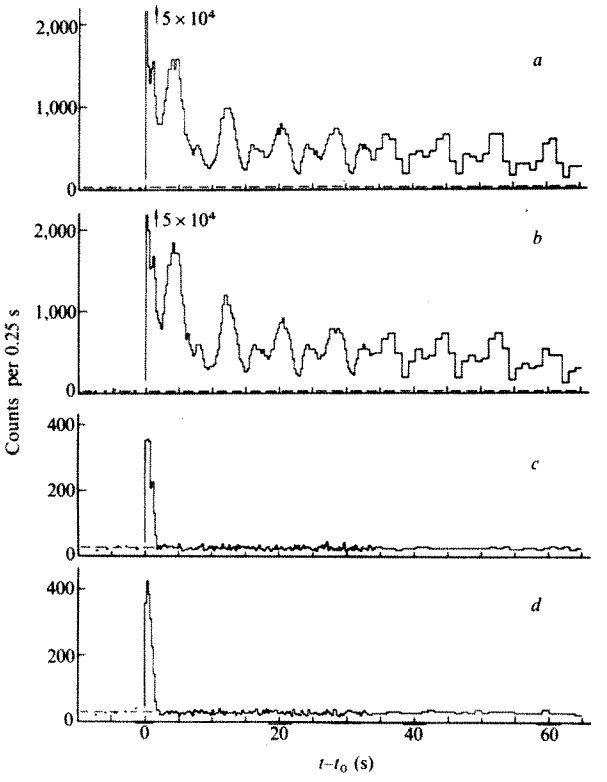

Fig. 2 Time structure of the bursts with resolution 1/4 and 1 s in the energy range 50–150 keV. *a*, 5 March, Venera 12; *b*, 5 March, Venera 11; *c*, 6 March, Venera 12: t_0 = 6 h 17 min 30 s, 455 UT. *d*, 6 March, Venera 11: t_0 = 6 h 17 min 25 s, 200 UT. Dashed line indicates background count rate. Points before t_0 show previous history of the bursts.

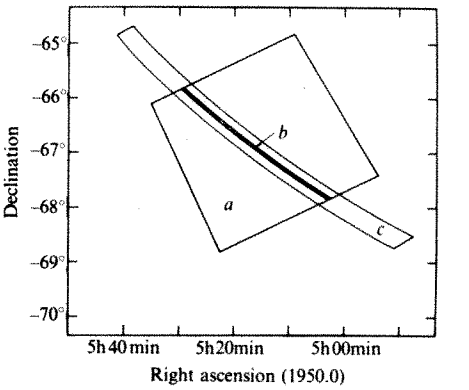

Fig. 4 Location of FXP 0520−66 source. Error box: *a*, for 5 March event, determined from detector anisotropic angular response; *b*, for 5 March event, obtained from detector anglular response and time-of-arrival difference; *c*, same for 6 March event.

markedly from the known transient sources[5]. It is unlikely that this source is the only one in the Galaxy. Other such sources probably exist and should be observable. However, the distances to them shoud be, on average, much larger, about a few kpc. Therefore, the observable radiation flux from such sources should be small. This implies that flaring X-ray pulsars could be detected primarily in their initial impulsive phase as short bursts of hard X-ray radiation.

Do the abovementioned differences in the spectral characteristics indicate that a binary cannot be the origin of γ-ray bursts? Apparently, not. Indeed, the revealed concentration of the γ-burst source locations in the direction of the galactic centre implies that distances to them are large and should be, on average, a few kpc (ref. 4). The corresponding estimates of the average energy released in γ-ray burst sources, 10^{40}–10^{41} erg, yield a value of 10^{39}–10^{40} erg s^{-1} for the average luminosity. These values exceed by at least 2 orders of magnitude the luminosity of known binary X-ray sources, as well as that of the FXP0520−66 source in its pulsating stage. Therefore, it is natural to suggest that the hardness and the shape of the radiation spectrum are substantially dependent on accretion rate, and it is the very high power of non-stationary accretion that determines the typically hard energy spectra of the γ-ray bursts that approach the power law in shape. The presence in the 5 March event of a hard component in the energy spectrum of the powerful initial impulse strongly supports this assumption.

X-ray observations of the 5 March 1979 γ-burst field

David J. Helfand & Knox S. Long

Columbia Astrophysics Laboratory, Departments of Astronomy and Physics, Columbia University, 538 West 120th Street, New York, New York 10027

On 5 March 1979, an extremely intense burst of hard X rays and γ rays was recorded by the nine interplanetary spacecraft of the burst sensor network and localised by time-of-flight determinations to a position coincident with the supernova remnant N49 in the Large Magellanic Cloud[1–3]. Several times, both before and after the γ-ray event, we observed this region of the sky with the soft X-ray imaging instruments aboard the Einstein Observatory. Coupled with optical plate material, the soft X-ray data are used here to place severe constraints on models for the origin of this remarkable transient phenomenon.

The γ-ray observations are reported in the preceding letter[2]. Briefly, the salient features of the event include an extremely high peak flux (1.5×10^{-3} erg (cm^2 s)$^{-1}$ above 30 keV), a rapid rise time ($\leq$0.25 ms, ref. 1), a decline to a flux level 10^{-2} times that of the peak within a second, followed by a slow (~100 s) decay characterised by 8.1-s pulsations, a soft γ-ray spectrum which during the initial burst shows evidence of a line feature near 430 keV, and a second much weaker burst 14 h later. The morphology, period and spectrum of the pulsed component are reminiscent of pulsating binary X-ray sources, such as Her X-1 and Cen X-3, which are thought to contain magnetised rotating neutron stars and to be powered by accretion from a normal companion star. The case for the presence of a neutron star in the system responsible for the γ-ray event is strengthened if one interprets the 430 keV emission line as redshifted electron–positron annihilation radiation. The implied gravitational field is just that found due to a $1M_\odot$ object with a radius of 10 km. The positional coincidence of the γ-ray event and a supernova remnant (SNR) might be cited as further evidence that a neutron star was involved; however, the luminosities implied by the association of this event with the Large Magellanic Cloud are quite large: $L_\gamma\sim5\times10^{44}$ erg s^{-1} at the burst peak and $L_\gamma\sim4\times10^{42}$ erg s^{-1} during the pulsing phase. In what follows, the X-ray data are presented and then used to set limits on possible interpretations for the origin of the event.

The X-ray observations were carried out as part of a complete soft X-ray survey of the Large Magellanic Cloud that has been underway since the beginning of the year[4]. The instrumentation of the Einstein Observatory has been described elsewhere[5]. With the imaging proportional counter (IPC) in the focal plane of the telescope, a $1°\times1°$ field of view is imaged with a spatial resolution of 1.5′ (FWHM), while the spatial resolution obtainable with the high resolution imager (HRI) over a $25'\times25'$ field is 4″. The initial IPC pointing, which occurred 8 days before the burst, revealed the presence of two bright sources of soft X-ray emission centred on N49 and (N49), emission nebulae in the Large Magellanic Cloud previously identified as SNRs[6]. With the moderate resolution of the IPC, N49 was unresolved; its companion 6′ to the north-west showed some evidence of extended structure. The results of the subsequent HRI observations are shown in Fig. 1. The source associated with (N49) is seen to be a uniform, symmetric emission region with a diameter of ~40 pc. By contrast, N49 is ~25 pc in diameter with a strong enhancement in the south-east quadrant and bright knots of emission similar to those observed by Dopita and Mathewson[7] and D. Clark (personal communication) in recent maps of coronal [Fe XIV] emission. A detailed discussion of the X-ray structure of SNR in the Large Magellanic Cloud will be given elsewhere. Here, we concentrate on those aspects of the data relevant to the 5 March event.

Our first important constraint on models for the γ-ray burst derives from the constancy of the flux from the N49 region in the two IPC observations carried out 0.72×10^6 s before and 3.29×10^6 s after the γ-ray event. We can quantify this constancy, independent of instrumental or background effects, by taking the ratio of the flux in the region of N49 to that from (N49). These ratios in the two IPC images are 2.167 ± 0.09 and 2.185 ± 0.09, corresponding to a limit on the change in flux from N49 of $<0.8\%^{+2.9\%}_{-0.8\%}$. Assuming a power law spectral index of −2 and a low energy cutoff of 0.5 keV, this corresponds to a 3σ upper limit on the change in flux of 2.2×10^{-12} erg (cm^2 s)$^{-1}$.

The improved spatial resolution of the HRI permits us to derive a second result—namely, a limit on the strength of any point source within the instrument's $25'\times25'$ field of view. This limit is obtained by summing the number of counts detected in $8''\times8''$ regions of the map and then subtracting a local background counting rate determined from the eight adjacent regions. The limits thus obtained depend on the mean surface brightness of the area being searched. For the region of extended emission within N49, the 3σ upper limit is 9.9×10^{-3} c.p.s., whereas for the area outside N49 but still near the γ-ray error box, the limit is $\sim10^{-3}$ c.p.s. These point source limits correspond respectively to flux limits of 2.1×10^{-12} erg (cm^2 s)$^{-1}$ and 2.2×10^{-13} erg (cm^2 s)$^{-1}$ (0.5–4.5 keV). The greater of these two values is therefore essentially the same as the limit to any change in flux derived from the IPC.

These X-ray limits imply that, independent of distance, the steady-state (or remnant) luminosity from the system which produced the γ-ray event is less than 10^{-9} that observed above 30 keV in the burst. This translates to a luminosity limit of $2\times10^{30}\,d_{100}^2$ erg s^{-1}, where d_{100} is the distance to the source in units of 100 pc. At the Large Magellanic Cloud, the limit on L_x is $<4\times10^{35}$ erg s^{-1}, two orders of magnitude smaller than that of a typical pulsating binary X-ray source.

In Table 1, we present these limits along with the γ-ray luminosities and energies and a variety of model-dependent

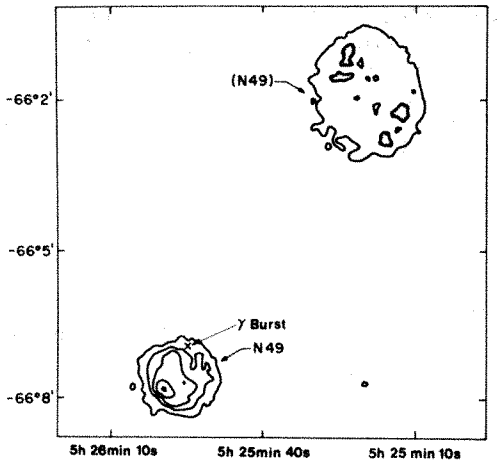

Fig. 1 Surface brightness contour map of the region containing N49 and (N49) as observed with the HRI. The map has been smoothed by convolving the raw data with a gaussian with a σ of 3″. The contour levels correspond to 0.025, 0.10, 0.20, 0.40 and 0.62 counts $[(1'\times 1')\,s]^{-1}$. The lowest contour ($\sim 3\sigma$ above the mean background level) corresponds to an equivalent flux of approximately 10^{-6} erg $(cm^2\,s\,keV)^{-1}$ in the energy range 0.5–4.5 keV. The position of the γ-ray burst (ref. 1) is shown; preliminary errors on this position are ~1.25′ in right ascension and 1.5′ in declination.

constraints implied by the observations. The sample distances are for a very nearby object (1 pc; see below), 200 pc suggested by Mazets *et al.*[2], 2 kpc corresponding to the limit for a galactic object in this direction ($|z|<1$ kpc), and 55 kpc, the distance of the Large Magellanic Cloud[8]. The neutron star temperature limits T_{ns} have been derived by convolving the radiation expected from an isotropically emitting black body of radius 10 km with the transmission characteristics of the interstellar medium (see ref. 9 for details). The masses of material involved in burst I on 5 March and burst II the following day, m_I and m_{II}, have been derived from the expression

$$m = \frac{E_\gamma}{c^2}\frac{1}{\eta_b} \qquad (1)$$

The results scale linearly with η_b, the efficiency with which the rest mass energy is converted to γ rays above 30 keV; as an example we have adopted a value of $\eta_b = 0.03$ appropriate for the conversion of hydrogen to helium in a thermonuclear flash. An interim mass accretion rate $\dot{m}_{I-II}$ is implied if the mass involved in burst II was accumulated between the events, while an upper limit to the steady-state accretion rate $\dot{m}_x$ can be derived from the X-ray observations:

$$\dot{m}_x < \frac{L_x}{c^2}\frac{1}{\eta_x} \qquad (2)$$

where the standard value for the conversion of accreted material to X rays in a typical X-ray binary system of $\eta_x = 0.1$ has been used. These two values imply that the accretion rate is highly variable, since

$$\frac{\dot{m}_{I-II}}{\dot{m}_x} > 200\frac{\eta_x}{\eta_b} \qquad (3)$$

Finally, the spectral type of any normal star associated with the system responsible for the burst is constrained by the fact that there is no star brighter than $m_B \sim 14.5$ on the ESO sky survey blue plate near or within the γ-ray error box; this observation rules out all but late-type, main sequence companions for the galactic distances and supergiant companions in the Large Magellanic Cloud.

Having tabulated these results, we consider the probable nature and distance of the system which produced the γ-ray event.

The remarkable positional coincidence of the γ-ray burst and N49 shown in Fig. 1 is the strongest argument for locating the system responsible in the Large Magellanic Cloud. Mazets *et al.*[2] reject this hypothesis because of the luminosities it implies. However, their implicit application of Eddington-limited accretion to the luminosity during the pulsation phase is clearly not required for such nonsteady flow. For example, the observed pulsed luminosity of 4×10^{42} erg s^{-1} (for a 55-kpc distance) is consistent with the thermal emission expected from a hot polar region with the observed temperature of 30 keV covering 10% of a neutron star surface. While current opinion seems to favour a galactic origin for γ-ray bursts[10], their spatial distribution is isotropic and consistent with an extragalactic origin. The fact that this burst was extremely bright may simply reflect its location in our nearest extragalactic neighbour, the Large Magellanic Cloud. However, this argument encounters severe difficulties if we assume that, despite some spectral and temporal differences, this γ-ray event is a manifestation of the same underlying phenomenon which produces all γ-ray bursts. The 5 March event was a factor of 10^2–10^3 more intense than other observed bursts. For an intrinsic spread in burst luminosities of an order of magnitude, this implies that the event was between 3 and 100 times closer than other bursts. An origin in the Large Magellanic Cloud, then, implies typical distances of 0.2 to 5 Mpc

Table 1 γ-Ray burst parameters

Parameter	Distance (pc)			
	1	200	2,000	55,000
$L_{\gamma I}$ (peak) (erg s^{-1})	2×10^{35}	7×10^{39}	7×10^{41}	5×10^{44}
$L_{\gamma I}$ (pulsed) (erg s^{-1})	1×10^{33}	5×10^{37}	5×10^{39}	4×10^{42}
$E_{\gamma I}$ (erg)	1.5×10^{35}	6×10^{39}	6×10^{41}	4.5×10^{44}
$E_{\gamma II}$ (erg)	1.5×10^{33}	6×10^{37}	6×10^{39}	4.6×10^{42}
L_x and ΔL_x (erg s^{-1})	$<1\times 10^{26}$	$<5\times 10^{30}$	$<5\times 10^{32}$	$<3.5\times 10^{35}$
T^*_{ns} (K)	$<1\times 10^{5}$	$<3.5\times 10^{5}$	$<9\times 10^{5}$	$<3.5\times 10^{6}$
m_I (g)	6×10^{15}	2×10^{20}	2×10^{22}	1.5×10^{25}
m_{II} (g)	6×10^{13}	2×10^{18}	2×10^{20}	1.5×10^{23}
$\dot{m}_{I-II}$ (g s^{-1})	1×10^{9}	4×10^{13}	4×10^{15}	3×10^{18}
$\dot{m}_x$ (g s^{-1})	$<1.5\times 10^{6}$	$<6\times 10^{10}$	$<6\times 10^{12}$	$<4\times 10^{15}$
Companions allowed	None	Dwarfs and subdwarfs later than K5; white dwarfs	Dwarfs and subdwarfs later than FO; white dwarfs	All but supergiants

* Values of 1 cm^{-3} for the galactic interstellar hydrogen density and 10^{21} cm^{-2} for the total column density to the Large Magellanic Cloud have been adopted.

which represent a volume of space containing too few galaxies to produce an isotropic burst distribution. Thus, starting from the Large Magellanic Cloud hypothesis, we are forced to conclude that either this burst represents a distinct class of events as suggested by Cline *et al.*[3] with a different underlying mechanism, or that it was more than 10 times weaker than a typical burst implying mean intrinsic luminosities for this phenomenon of $>10^{46}$ erg s^{-1}.

The same distance scaling factors (3–100 times closer) also apply to a galactic hypothesis. For a scale height of 1 kpc which is consistent with the observed burst distribution[10], this event must have been located between 10 and 300 pc from the Earth. Models for the origin of such a nearby event are constrained by the various limits presented in Table 1. Neutron star temperature limits of a few hundred thousand degrees are only marginally consistent with those expected from undisturbed, isolated objects[9]. In addition, the various accretion rates coupled with the limits on an optical companion can be used to constrain the parameters of models containing binary systems.

By using the observation of the narrow 430-keV emission feature observed in the burst spectrum, we can derive another estimate of the source distance. If this feature is real, an upper limit to the distance of the neutron star may be obtained if we assume that the continuum emission arises from electron bremsstrahlung and that the emission region (assumed for simplicity to be spherical and of uniform density) is the same for both the line and the continuum. For a narrow line feature to exist, the electron scattering depth must not greatly exceed unity; that is,

$$\sigma n_e r = \tau_{es} \lesssim 1 \tag{4}$$

where σ is the electron scattering cross-section at 430 keV, n_e is the ambient electron density and r is the radius of the emission region. The distance of the event determined from the continuum radiation is given by

$$d = 3^{-1/2} F^{-1/2} \varepsilon^{1/2} n_e r^{3/2} \tag{5}$$

where F is the continuum flux and $\varepsilon (\sim 1.64 \times 10^{-27} T^{1/2}$ erg cm^{-3}) is the volume emissivity of a gas with unit density. Thus, in units appropriate if the positron line were present only during the initial fast part of the burst and assuming that the light travel time of this portion of the event sets a limit on the size of the emitting region, we have

$$d \lesssim 2.3 \times 10^{18} \left(\frac{1.5 \times 10^{-3} \text{ erg (cm}^2 \text{ s)}^{-1}}{F} \right)^{1/2} \times \left(\frac{T}{30 \text{ keV}} \right)^{1/4} \tau_{es} \left(\frac{t}{10^{-3} \text{ s}} \right)^{1/2} \text{cm} \tag{6}$$

which is <1 pc! Unfortunately, the time resolution of the spectra presented by Mazets *et al.*[2] is 4 s. If values for the continuum flux are determined over this interval and the diameter of the emitting volume is assumed to be 4 light s, the upper limit is still less than 100 pc. The closest distances are probably excluded, in that X rays from interstellar accretion onto an isolated neutron star would violate our point source flux limits. We note that for $d \lesssim 10$ pc, however, such an isolated star can accumulate sufficient interstellar material to satisfy the entire γ-ray burst energy requirements in <10 years.

Solar structure from global studies of the 5-minute oscillation

Instituto de Astrofisica de Canarias, La Laguna, Tenerife

High sensitivity Doppler spectroscopy of integral sunlight in the 769.9 nm line of neutral potassium reveals several equally spaced lines of $Q > 1{,}000$ centred on the well known period of 5 min. These lines are interpreted as low l, high n overtones of the entire Sun and, if viewed in terms of current solar models, appear to imply a low heavy element abundance and a consequent low solar neutrino flux. Previous workers[1–3] have used spatial resolution to study the 5-min oscillation of the solar photosphere and have shown that power is concentrated along narrow ridges in the k, ω diagram. These oscillations are mainly low n, high l value acoustic modes of the entire Sun. In contrast to this, the present work (for a summary see ref. 4) is aimed at an overall view of the solar surface and consequently is biased to a study of low l value oscillations. These modes penetrate deeply[5] and thus probe the structure as well as the interior angular velocity of the Sun[6].

Doppler shift measurements of integral solar light show several discrete lines of amplitude 0.1–0.3 m s^{-1} within the main peak of the power spectrum of the 5-min oscillation. These lines are found to have, on average, a uniform spacing of 67.8 μHz.

If the lines are interpreted as being due to low l value oscillations of the entire Sun, then the observed spacing taken in the context of current solar models[7,8] implies a mean heavy element abundance of $Z \sim 0.004$ and a consequent neutrino flux of ~2.3 SNU, within two standard deviations of the experimental result[9].

Line of sight velocity measurements of the whole solar disk were made using optical resonance spectroscopy, a technique

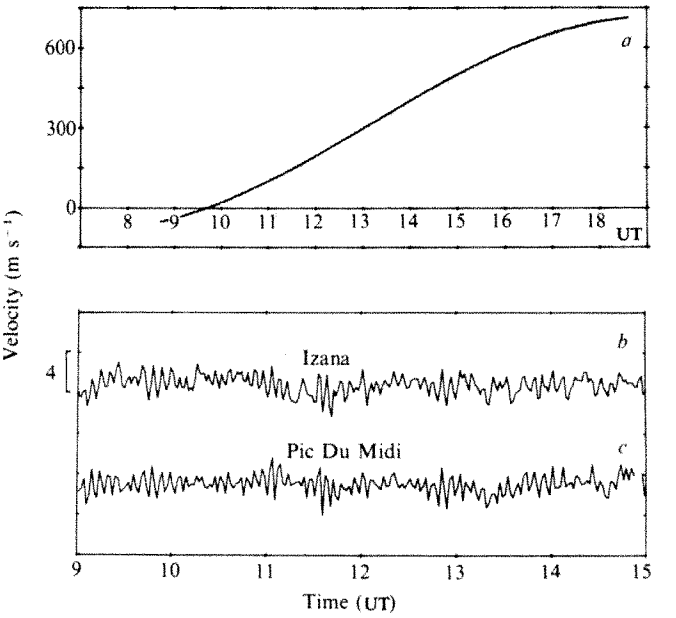

Fig. 1 Mean line of sight velocity observed on 6 August 1978 at Izana (*a*). Comparison of residuals obtained simultaneously at Izana (*b*) and Pic du Midi (*c*).

which has been described in detail previously[10]. Briefly, the velocity of the solar photosphere with respect to the laboratory is measured by comparing the position of the Fraunhofer absorption line of neutral potassium at 769.9 nm with that of the same line in the laboratory. Observations were made during 1976, 1977 and 1978 at Izana, Tenerife and in 1978 simultaneously at Pic du Midi in the Pyrenees. The two sites are ~2,300 km apart and are expected to be meteorologically uncorrelated, thus allowing solar effects to be distinguished from atmospheric or instrumental perturbations. In the 1977 and 1978 seasons the spectrometer incorporated substantial improvements with respect to guidance, optical components, thermal stability and statistical accuracy, resulting in the collection of data of improved quality.

The Sun was observed for about 8 h on each of 33 days in 1976 (a total of 269 h) and 35 days in 1977 (total 280 h). These data as well as those from 7 of the days obtained in 1978 have been analysed. The data for any one day consist of a mean line of sight velocity determined every 42 s (100 s on Pic du Midi) for the whole observing day (Fig. 1*a*). Residuals corresponding to velocity amplitudes of less than 3 ms^{-1} (Fig. 1*b*) show up after subtraction of the observer's velocity relative to the centroid of the Sun due to the spin and orbital velocities of the Earth. A small allowance for residual curvature effects has been made.

Residuals of data obtained simultaneously at the other observing site are shown for comparison in Fig. 1*c*. To compare these data directly, those from Izana have been smoothed by a moving mean over three points (126 s) and then summed over two points (84 s) to simulate the 100-s integration time of the Pic du Midi data. The correlation of these two data strings clearly demonstrates that the observed signals can only be attributed to a solar origin.

These residuals form a time series which may be processed using standard power spectrum techniques[11]. The power spectra obtained for the data of Fig. 1*b* and *c* are shown in Fig. 2. The agreement of these two spectra, obtained simultaneously at two sites separated by 2,300 km, clearly reinforces the statement that the observed oscillations are of solar origin. A series of well defined peaks can also be seen.

To investigate these peaks further the power spectra for individual days were averaged for the 1976, 1977 and 1978 data. These spectra are shown in Fig. 3. The structure is clearly present and an apparent constancy in the spacing of these peaks can be seen. To verify that this spacing is not an artefact of the analysis, different lengths of data strings were used but this had no effect on the observed spacing.

The constancy of the peak spacing may be demonstrated in two ways. First, the observed peaks in the power spectra are numbered sequentially and plots of the order of the peak against the observed frequency are shown in Fig. 4*a* for the 3 yr of data. Where the line spacing clearly suggests that a particular line is absent in the experimental data, the order of the line has been

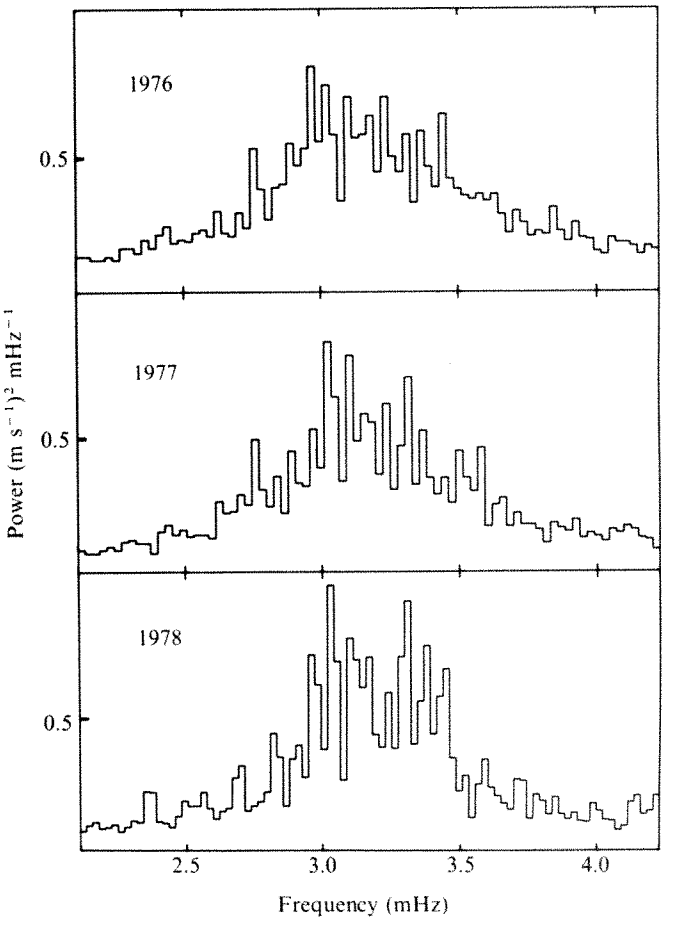

Fig. 3 Mean power spectra obtained from data collected over 33 days in 1976, 35 days in 1977 and 7 days in 1978 at Izana.

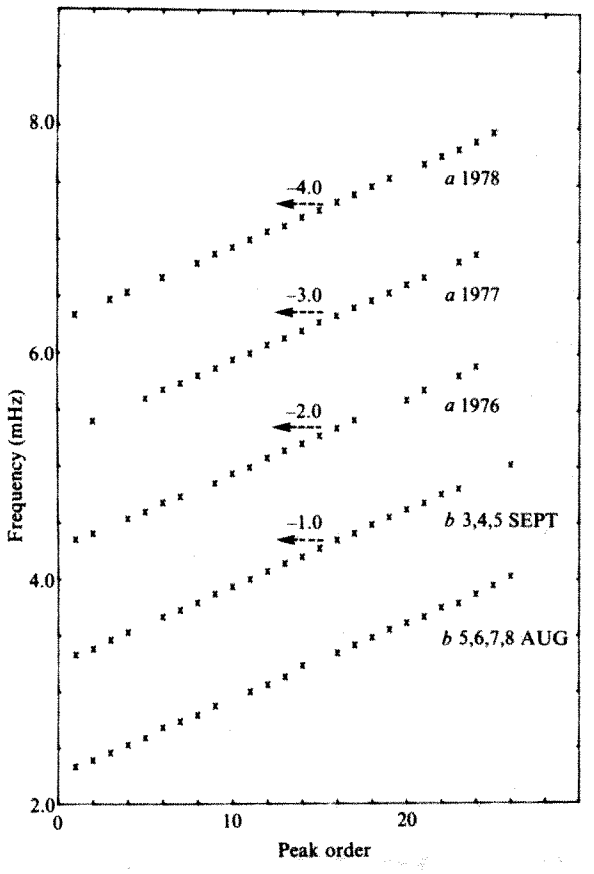

Fig. 4 *a*, Peak frequency against order plotted for the mean power spectra of 1976, 1977 and 1978. Successive plots are displaced by 1 mHz on the vertical scale as indicated. *b*, Similar plots for data determined by a superimposed epoch analysis for 4 days in August and 3 days in September 1978.

appropriately increased. The data are well fitted by straight lines and yield mean spacings of 67.6, 67.4 and 67.6 μHz for the 3 yr. Second, the mean power spectra data are screened by a high pass filter by subtracting a moving mean over three points, and then subjecting the resulting points to an autocorrelation and power spectrum analysis. In this way mean line spacings of 67.8, 68.0 and 68.0 μHz are found for the 3 yr. A cross-correlation analysis of the 1976 and 1977 power spectra yields a correlation coefficient of 0.89 and has a maximum at zero frequency lag. This firmly establishes the consistency of the lines over the 2 yr.

As an alternative form of treatment, the data of 1978, which are of higher quality due to improvements in experimental technique, were subjected to a superimposed epoch analysis. Four consecutive days in early August and three in September were used for this study, the frequency range being restricted to that covered by the power spectrum analysis. The structure found in the power spectrum analysis was again evident and a plot of the frequency against peak order is shown in Fig. 4*b*. Straight line fits to these plots yielded mean line spacings of 67.4 ± 0.5 and 67.9 ± 0.2 μHz, respectively. The results of the superimposed epoch analysis over the four consecutive days seem to imply that the Q value of these oscillations is $>1{,}000$.

To investigate further the coherence of the oscillation, a power spectrum analysis of two consecutive days of data was undertaken with zeros in the data string corresponding to the times when actual data were not available. This resulted in a 32-h data string whose power spectrum is shown in Fig. 5*a*. The usual peaks in the power spectrum are clearly evident. To test for the coherence of these peaks sine waves of the indicated frequencies were subtracted from the original data by using a least squares fitting procedure to optimise the frequency, phase and amplitude of the fitted wave. The new power spectrum obtained after subtraction of these coherent fitted sine waves from the data is shown in Fig. 5*b*. This clearly demonstrates that the oscillations are coherent over the 32-h data string and thus have a $Q > 400$.

It seems likely that these lines correspond to normal modes of vibration of the whole Sun. To identify these modes with certainty, information on their spatial structure is required. An integral light spectrometer tends to average out modes of high l value with many peaks and troughs across the visible disk of the Sun[6], thus strongly biasing the observations towards low l value modes. An approximate calculation of the sensitivity of a velocity spectrometer to various spherical harmonic modes can be found elsewhere[13] but a more precise evaluation must include the spectral weighting function across the solar disk[14]. The above suggests that the observed modes are of low l value, possibly $l = 0$ and $l = 1$, with even and odd l values alternating as the value of n (number of radial nodes) increases. The observed mean spacing of 135.6 ± 0.3 μHz of next nearest lines falls in the range of spacings (130–142 μHz) predicted by solar models with uniform, as well as surface enhanced, heavy element abundances. An extrapolation of the uniform model calculations[7]

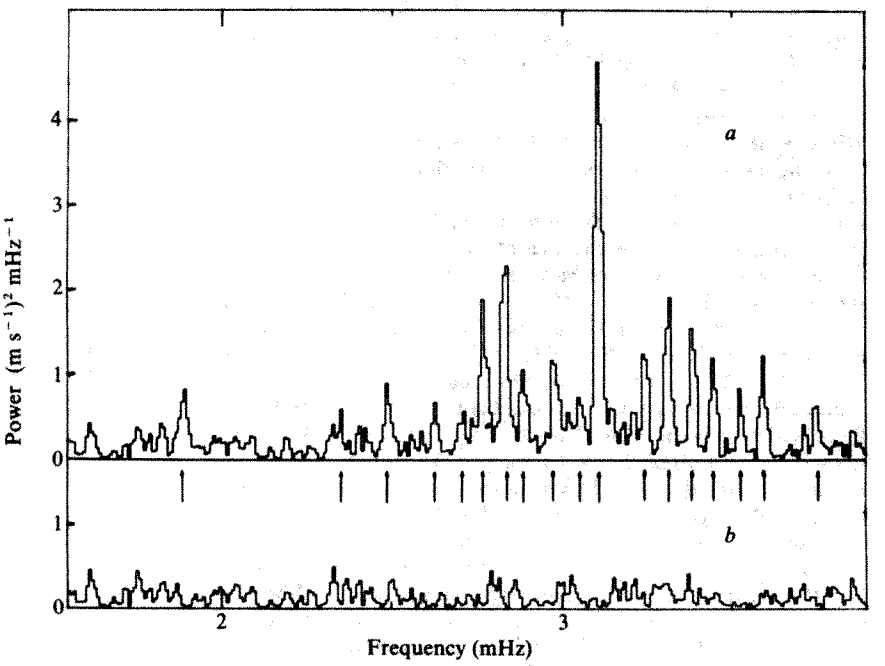

Fig. 5 *a*, Power spectra of two consecutive days of data obtained at Izana on 4 and 5 August 1978. *b*, Power spectra of the same data after subtraction of indicated discrete frequencies.

suggests that the observed spacing is consistent with a heavy element abundance of $Z \sim 0.002$. An interpolation of the non-uniform model predictions[8], with a surface heavy element abundance of 0.02, indicates that a mean heavy element abundance of $Z \sim 0.004$ closely fits the observed spacing. Assignment of the lines to l values ≥ 2 is either not consistent with the uniform model[7] or leads to even lower Z values for the non-uniform model[8]. This suggests that any interpretation in terms of these models implies a Z value ≤ 0.004 and a solar neutrino flux of ≤ 2.3 SNU, consistent with the observed value of 1.75 ± 0.4 SNU[9].

Values of n can be tentatively assigned to the lines using the uniform model for which frequencies of particular modes in this region[7] have been calculated. Using the low l value assignment and the approximate Z value limit quoted above, the observed frequencies of 2.41 and 4.04 mHz are tentatively identified as $l = 0$ modes with $n = 17$ and 29, respectively. Such an identification is consistent with the observed slight inequality in spacing between alternate lines. Thus, if the frequencies ν of two neighbouring $l = 0$ lines are compared with that of an $l = 1$ line, as expected[7], $\frac{1}{2}(\nu_{n+1,0} + \nu_{n,0}) > \nu_{\text{odd}}$. The heavy element abundance corresponding to this identification is near $Z = 0.004$.

The discrete lines are expected to be hitherto unresolved multiplets due to incomplete degeneracy of different n, l contributions. Rotation of the Sun is further expected to split the modes into $(2l + 1)$ components of spacing characterised by the mean angular velocity of the interior[6,14]. This will produce a long period amplitude modulation of the lines, some evidence for which already exists. It should be possible to resolve this fine structure by using long data strings, provided that the coherence time is adequate.

The definite assignment of the various modes is being attempted by a two-dimensional study of the solar photosphere. The amplitude variation of particular lines, as well as phase information, is being analysed further to study the excitation and damping mechanisms.

We thank B. A. Hail, J. W. Litherland, P. Morris and C. P. Sutton for technical assistance, and Professors J. Rösch and F. Sánchez Martinez for their hospitality at the two observing sites. This work was supported by the SRC and A.C. acknowledges a research associateship. T.R.C. thanks the Spanish Government for a maintenance grant during this work.

Spurious radiation from microwave ovens

B. Anderson, R. Pritchard & B. Rowson

University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire, UK

In agreement with the regulations of the International Telecommunication Union the manufacturers of microwave ovens are licensed to operate within the frequency band 2.45 ± 0.05 GHz reserved for industrial, scientific and medical purposes. Evidence that microwave ovens emitted significant amounts of radiation outside this licensed band and covering the reserved bands allocated to radioastronomy and communications was given in a report prepared for the Royal Society and Ministry of Technology in 1969[1]. No action was taken by the licensing authorities to enforce restrictions on this spurious radiation and because the use of microwave ovens has become widespread we have made and report here a new series of measurements to assess the extent of this radiation from the ovens now in use. Our main concern has been with the spread of the oven radiation into four of the bands protected internationally for the use of radioastronomers: 1,400–1,427 MHz (21 cm H-line band); 1,660–1,670 MHz (18 cm OH band); 2,690–2,700 MHz (11 cm S-band); 4,990–5,000 MHz (6 cm C band). Although our primary interest has been to estimate the limitations which may be placed on the performance of the radio telescopes at Jodrell Bank by microwave ovens used in the vicinity, the results are relevant to the communication systems that are allocated nearby frequency bands.

Measurements have been made on three ovens from different manufacturers; two were new domestic models currently on sale and the third was a larger commercial model that had been in service for 10 years and was coated with deposits of grease and grime. As it is unwise to operate the ovens without a load, a beaker containing approximately 300 ml of water was placed centrally on the shelf of the oven. The radiation levels were measured with a tunable receiver connected to a log-periodic antenna having nearly constant gain over the band 1–6 GHz. The receiver sensitivity was measured by means of a calibrated signal generator.

It was established that the received signal did not depend significantly on the polarisation of the antenna. The data presented here were obtained with the antenna vertically polarised and directed at the front of the oven from a distance of 3 m. Figure 1 shows an oscilloscope display of the total power received by the antenna in a bandwidth of several gigahertz (*b*), and the power received in a 7 MHz bandwidth centred on 2,695 MHz (*a*). The oscilloscope time base was triggered at a rate of 50 Hz; the exposure time was 1 s. The rotation of the

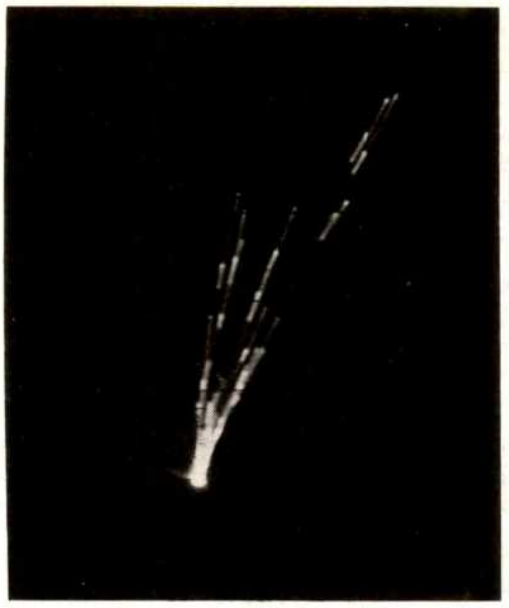

Fig. 2 A polar display of the instantaneous frequency of the major component received by the antenna. The radial distance from the bright spot is a measure of the intensity and the azimuthal angle is a measure of the frequency. One rotation covers 88 MHz.

metal paddle inside the oven was inhibited during the exposures. Movement of the paddle by hand affected the amplitude of the lower trace and caused the position of the short pulses on the top trace to move back and forth in time. Tuning the receiver centre frequency over tens of MHz had the same effect on the short pulses.

Essentially the same behaviour was observed wherever the receiver was tuned between 1 and 6 GHz except that the top trace became similar to the bottom trace near and below the nominal oven operating frequency of 2.45 GHz and also near the second harmonic at 4.9 GHz. With the paddle stationary, it was possible to find restricted regions of the spectrum where the radiation was below our limit of detection in a 7 MHz bandwidth but these quiet regions were much less frequent if the paddle was rotating.

Figure 2 shows a polar display of the total power (radial distance) versus instantaneous frequency (position angle of the trace with respect to the bright central spot) received by the antenna. A 90° difference in position angle corresponds to a frequency difference of 22 MHz. Each 'finger' on the photograph is a mode of the oven and the trace intensity is proportional to the probability of finding the output at that power and frequency. The largest observed separation of the modes was ~30 MHz. It seems, therefore, that the major components of emission fall within the frequency limits specified.

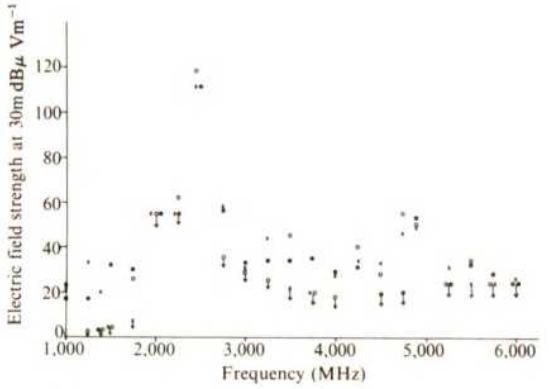

Fig. 3 Electric field strength at a distance of 30 m as a function of frequency for the radiation from three microwave ovens: ○, used commercial oven; × and ●, new domestic ovens.

Figure 3 shows the peak value of the electric field components of the spurious emissions from the ovens measured in a 30 kHz bandwidth and normalised to a range of 30 m (assuming an inverse square relationship for power). The measurements are plotted for all three ovens at 0.25 GHz intervals between 1 and 6 GHz. These data are in good agreement with earlier Post Office measurements of a completely different set of ovens manufactured between 1962 and 1968 (ref. 1).

The interference effects from microwave ovens on radio telescopes working in the frequency bands allocated for astronomical purposes and listed above have been calculated as follows. The receiving system on a telescope generates a noise signal, P_N, in the receiver bandwidth, B, equivalent to a mean input power given by

$$P_N = kT_sB\,\mathrm{W}$$

where k is Boltzmann's constant and T_s is the effective system noise temperature in degrees Kelvin. If the receiver output is averaged for a time τ, the input power can be established with a statistical uncertainty

$$\delta P_N = kT_s(B/2\tau)^{1/2}$$

Signals from radio sources that add more power to the receiver than δP_N can be detected with a statistical confidence dependent on the factor by which the added power exceed δP_N in the usual way for a normal error distribution.

Table 1 Specification of the maximum levels of radiation in the 1 to 6 GHz band from interfering sources assuming T_s is 30 K

A Mean power from interfering source	$<2\times10^{-20}$ W in 10 MHz bandwidth $<0{\cdot}65\times10^{-21}$ W in 10 kHz bandwidth $<0{\cdot}65\times10^{-22}$ W in 100 Hz bandwidth	assuming $\tau = 2\times10^{3}$ s	
B Peak power averaged over 1 ms	$<2.8\times10^{-17}$ W in 10 MHz bandwidth		($\delta t = 10^{-3}$ s)
C Peak power averaged over 1 ms of a repetitive signal with period > several milliseconds	$<2.8\times10^{-19}$ W in 10 MHz bandwidth		($N\delta t = 10$ s)

Many astronomical radio sources have continuous spectra so that the telescope receives from the source a power proportional to the receiver bandwidth. A larger value of B then increases the signal-to-noise ratio despite the proportionality of δP_N to $(B)^{1/2}$. A long integration time also improves the signal-to-noise ratio for those sources for which the intensity is not a function of time. In the case of pulsars where the intensity of the source is a function of time, τ is limited to the desired time resolution, δt, if the purpose is to study the structure of a single pulse, or to $N\delta t$ if the purpose is to study the integrated profile of N pulses with time resolution δt.

The power received from interfering sources is not generally constant as a function of time: either the source emission varies or the telescope sweeps its sidelobe structure over the source as it tracks an astronomical object. The net result in either case is to increase the fluctuations in the receiver output above the natural limit and hence impair the sensitivity of the radio telescope. The power received from interfering sources must be below δP_N if the performance of the telescope is not to be affected.

On this basis, limits may be placed on the tolerable power levels of interference for a radio telescope. These limits are given in Table 1 assuming that the system noise temperature, T_s, is 30 K. It must be stressed that Table 1 is based on assumptions and limits which are typical of contemporary systems used in radioastronomy and are, in fact, 10 times less severe than the

CCIR Report on the protection criteria for radioastronomy[2]. On the other hand, we assume that there is only one source of interference which is not likely to be the case if microwave ovens become widespread.

The power (P_i) received from an interfering source by a radio telescope depends on the equivalent isotropically radiated power (EIRP) of the source in the direction of the telescope, the range of the source from the telescope (R_i), and the gain of the telescope (G_i) in the direction of the source. The relationship between these parameters is

$$P_i = (EIRP)G_i(\lambda_i/4\pi R_i)^2$$

where λ_i is the wavelength of the radiation. The appropriate G_i to use in the case of a ground-based source of interference is that of a far-out sidelobe of the telescope response for which $G_i \sim 1$ (a −63 dB sidelobe for a 80-m telescope at $\lambda \simeq 12$ cm).

Measurements were made on the interference from one of the domestic ovens in the protected frequency bands for radioastronomy shown in Table 1. The results are shown in Table 2 together with a comparison with limits A and C of Table 1. These results have been converted to levels received by a radio telescope at a range of 1 km assuming that G_i is 1 and that power flux density is $\propto R_i^{-2}$. Measurements were also made 50 MHz on either side of each of these bands as it was thought that there might be nulls in the spectrum that were oven-load dependent or not repeatable from oven to oven.

The data presented in Table 2 show that spurious emissions from microwave ovens present a serious danger to radioastronomical researches and at some parts of the spectrum they are at a level that would degrade the performance of a point-to-point radio link where the possibility of having an oven in the main beam of, and close to, a receiver cannot be discounted.

The power levels given in Table 2 for the four protected frequency bands have been used to derive the data given in Table 3 for the influence of a single oven operating at various distances from a radio telescope with a sidelobe level with a gain equivalent to an isotropic radiator. Table 3 makes no allowances for any screening of the oven that may be provided by the walls of buildings, or other obstructions. The Post Office report[1] estimates that up to 30 dB attenuation of the signals may be caused by such obstructions but this form of screening cannot be relied on—a glass window is relatively transparent to microwaves and an average kitchen window would allow spurious emissions from an oven to escape unattenuated over a wide range of angles.

The emission of significant microwave power over such a wide spectral range seems to arise from the method of generation of the power coupled with the ineffective shielding at the seals of the oven door. The source of the microwaves is a magnetron producing 1–2 kW of power and operating from rectified but unsmoothed a.c. mains. The power is generated for approximately half of each supply cycle. The magnetron drives a load that is deliberately disturbed by a rotating metal paddle in the oven with the consequence that both the instantaneous frequency at which it oscillates and the power that it delivers are functions of time. The instantaneous frequency lies in the assigned band of 2,450 ± 50 MHz but modulation sidebands exist and it is these which give the out-of-band emissions. It is also possible that some of the spurious emissions are caused by instabilities in the electron distribution inside the magnetron leading to the generation of unwanted frequencies[3,4].

The primary source of leakage of radiation is from the seals around the door which fail to confine the microwave radiation to the inside of the oven[5]. These seals are non-contacting and seem to consist of a resonant, quarter-wavelength choke nominally tuned to 2,450 MHz followed by microwave absorbing material. The seals are sufficiently effective in the assigned band of 2,450 MHz to satisfy the safety regulations appropriate to the UK[6], but they fail to give adequate out-of-band suppression to prevent possible interference with other services authorised to operate within the 1–6 GHz frequency band.

The measurements of the spurious emission from microwave ovens over the frequency band 1–6 GHz are in substantial agreement with those reported previously[1]. In particular these emissions cover at least four of the frequency bands which are allocated by the ITU to radioastronomy. Increasing use of the ovens in the vicinity of radio astronomical installations and of communication systems working in this frequency range would place serious limitations on the operation of these installations. Whereas the Radio Regulatory Department of the Home Office place stringent limits on the amount of the spurious radiation which is allowed from communication systems no such limits seem to be imposed on the amount of the out-of-band radiation allowed from microwave ovens.

The design of the ovens on sale in UK is governed by a directive[6] which recommends an upper limit for continuous exposure of 10 mW cm^{-2} and specifies that the test equipment should be capable of measuring to 1 mW cm^{-2} and preferably to 0.5 mW cm^{-2}. Furthermore it is specified that the equipment used for the measurements should be "relatively insensitive outside its declared frequency band". The measurements reported here reveal that this specification (laid down in 1960) is not sufficient. The regulations need revision so that the use of microwave ovens is not allowed if the amount of the emitted radiation outside the licensed band of 2,450 ± 50 MHz can cause harmful interference to authorised radio services.

Table 2 Levels of interference from a microwave oven at a distance of 1 km for radiation received in a far-out sidelobe ($G = 1$)

Frequency (MHz)	Mean power into receiver at 1 km, 10 Mhz BW (W)	Peak power into Rx at 1 km 10 MHz BW (W)	Factor by which mean exceeds limit A of Table 1	Factor by which peak exceeds limit C of Table 1
1,365	5×10^{-20}	$2{\cdot}5\times10^{-18}$	2.5	9

Corrosion micromorphology of noble metal alloys and depletion gilding

A. J. Forty

Department of Physics, University of Warwick, Coventry, UK

Noble metal alloys commonly undergo selective dissolution during anodic corrosion whereby the less noble component is dissolved preferentially. This is particularly interesting, as it leads to a depletion of the less noble species not only at the surface of the metal but also at an appreciable depth within it, implying that a mass transport of atoms is occurring either through the bulk of the crystal lattice or across the surface to support the continuing dissolution. Experiments in which the micromorphology of silver–gold alloys is observed during such corrosive treatment have shown that surface diffusion of gold plays an important part in this process. As surface silver atoms are dissolved the residual gold atoms reform into gold-rich islands so that fresh silver atoms are continuously exposed to the environment layer by layer. These observations will be described in detail elsewhere[1]. Here the mechanism of surface re-arrangement is considered, which leads to the accumulation of gold-rich surface regions, and throws a new light on the ancient craft of depletion gilding.

Depletion gilding, or gold colouration (*mise-en-couleur*) is the process by which the surface of a dilute gold alloy becomes gold-enriched by the selective removal of the less noble component. This usually involves annealing the alloy or immersing it in a corrosive bath, or some combination of these treatments. It is well established that the Indians of pre-Columbian Central America had invented such a technique for the colouration of castings prepared from copper–gold alloy[2], commonly referred to as tumbago. Their colouring methods involved either the formation of copper oxide by heating in air, followed by chemical dissolution of the oxide or the slow removal of copper from the surface of the alloy in a corrosive bath. The 'spongy' gold layer so-formed was then consolidated by burnishing. It is thought that similar processes were used by North Peruvian craftsmen to colour objects fabricated from silver-based alloys[3]. However, the details of these processes, particularly the nature of the chemical reagents used, are still matters for conjecture.

A very closely related process for the colouration of silver–gold alloys, known as cementation, is known to have been used by European and Near Eastern goldsmiths since before the early Middle Ages. The object is packed in a reactive powder (invariably containing salt) which, when heated, forms soluble chlorides with silver and other impurities in the alloy, leaving the surface of the object gold-rich.

From the metallurgical point of view the most interesting aspect of these ancient crafts is the process by which the gold becomes parted from its alloys by the selective corrosion of the less noble components. Nitric acid has been used for parting silver and gold in Europe since the twelfth or thirteenth century. However, apart from the very superficial observation that nitric acid preferentially dissolves the silver, leaving the surface of the alloy coated with a spongy gold layer[4], there has been no detailed study of the metal physics of these surface enrichment processes. The micromorphological observations reported here may, however, provide some new insight into the understanding of these ancient technologies.

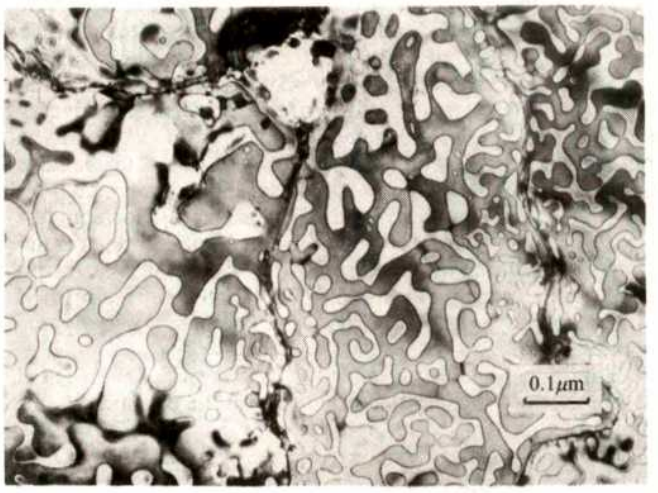

Fig. 1 Transmission electron micrograph of 50:50 Ag–Au alloy after corrosion in 50% nitric acid, showing island and channel morphology.

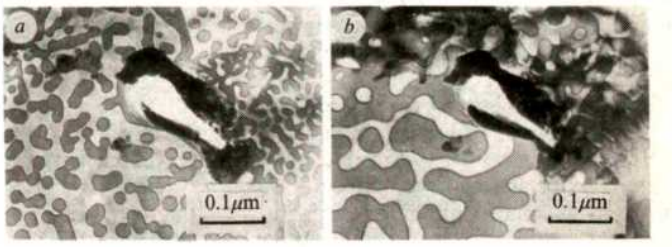

Fig. 2 Transmission electron micrograph of 50:50 Ag–Au alloy: *a*, after corrosion for 30 s in 50% nitric acid; *b* after corrosion for 60 s in 50% nitric acid.

Figure 1 shows a transmission electron micrograph of a single crystal thin film of a 50:50 silver–gold alloy after a small amount of corrosion in a 50% aqueous solution of nitric acid. The film, originally structureless, apart from a small number of dislocations, twins and double-positioning boundaries[5], has become transformed into a maze-like structure of island of more strongly absorbing material separated by more transparent channels. The selected area X-ray analysis facility available in the electron microscope, has shown that the island regions of the film are gold-rich compared with the channels, which is consistent with the suggestion that the islands are formed during corrosion by the aggregation of the gold residue on the surface after selective dissolution of silver. Figure 2 demonstrates how the islands grow and the channels between them shrink as the corrosion proceeds, and Fig. 3 shows how annealing at only 720 K after an initial exposure of the alloy to nitric acid causes the islands to grow and merge together to form a connected gold-rich surface layer with residual pits where the merger is incomplete. Similar observations on other silver–gold alloys and also copper–gold alloys over a wide range of compositions and exposed to a wide variety of acid environments have confirmed that the island nucleation and growth is common.

These corrosion-induced micromorphological changes can be explained on the basis of a model in which the selective dissolution of silver produces an atomic roughening of the surface

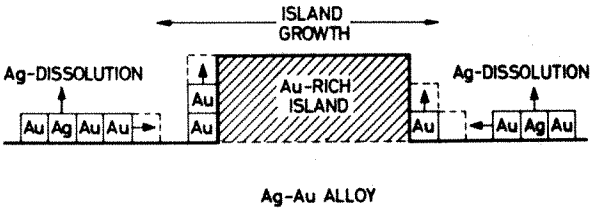

Fig. 4 Gold island growth by the surface disordering, reordering mechanism.

of the alloy (surface disordering). The surface disorder may be regarded as a random distribution of surface silver vacancies or surface gold adatoms, depending on whether the alloy is gold-rich or silver-rich. As the corrosion proceeds the surface reorders by island nucleation and growth from the high concentration of gold adatoms. This process is illustrated in Fig. 4. Finally, the islands grow into an interconnected structure resulting in a very thin epitaxed surface coating of gold.

Although these observations are made on single crystal, high purity alloys, specially prepared for corrosion studies[5], the surface disordering, reordering model can readily be extended to the more practical situation of depletion gilding of castings. The micromorphology of the gold-rich surface layer will vary in detail according to alloy composition, type and strength of acid used, local changes of composition and alloy microstructure at grain boundaries[1], but the final result is expected to be a thin tenacious coating of gold with imperfections which can be subsequently removed by a burnishing treatment.

It would be interesting to carry out a detailed micromorphological study of this kind on binary and ternary silver, copper and gold alloys after corrosion in reactive environments similar to those thought to be used by the ancient Indian goldsmiths.

I thank Professor Colin Goodman for drawing my attention to the Royal Academy Exhibition *The Gold of El Dorado* which caused me to connect my work on the corrosion morphology of silver–gold alloys with the art of depletion gilding.

Incorporation of elemental sulphur in coal as organic sulphur

Daniel J. Casagrande* & Lily Ng

Governors State University, Park Forest South, Illinois 60466

Organic sulphur can represent over 50% of the total sulphur content in coal[1], but little is known about the nature of this organic sulphur because of the chemical complexity of the coal structure and heterogeneity of the maceral assemblages forming the coal matrix. This report focuses on the mode of incorporation of organic sulphur in the very early stages of the coal-forming process. Some organic sulphur in coal originates from the sulphur-containing amino acids that are present in source plants in the peat-forming stage, but we demonstrate here that some of the organic sulphur in coal can actually originate from an inorganic sulphur source, such as elemental sulphur.

* Present address and address for reprints: Exxon Production Research Company, Box 2189, Houston, Texas 77001.

The coal-forming process is a geochemical continuum that includes: peat → lignite → bituminous coal → anthracite coal. Contemporary coal progenitors can be found in peat-forming systems of the Okefenokee Swamp, Georgia and the Everglades Swamp, Florida[2]. Each peat-forming system is a dynamic community composed of plants, surface litter, water, minerals, microorganisms and peat; in the case of the Okefenokee, its present vegetation is similar to that which gave rise to the huge Braunköhle accumulations in Germany and some of the lignites in the Dakotas[3,4].

Virtually all the sulphur in some coals can be accounted for in the peat-forming stage of coal formation[5]. The forms of sulphur that have been found in peat include pyrite, sulphate, hydrogen sulphide, elemental sulphur, carbon bonded (C–S) sulphur, and ester sulphate (C–O–S)[5,6]. Organic sulphur is the major variety of sulphur in virtually all peats studied: it represents over 60% of the total sulphur. One origin for the organic sulphur in peat is the sulphur-containing amino acids such as methionine, cystine and cysteine that are contributed to the sediment by decaying plants and associated microflora and microfauna, but less than 40% of the total organic sulphur can be accounted for as sulphur associated with amino acids[7]. As a function of depth, fewer sulphur-containing amino acids were observed in peat from a marine environment, even though total organic sulphur increased substantially with depth.

Initially, it was thought that the sulphur-containing amino acids were being incorporated via chemical reaction into the various organic fractions of the peat, such as humic and fulvic acids. Yet, in many peat profiles, organic sulphur increased to levels that were substantially greater than the source plant materials and certainly considerably higher than that found in the upper levels of the peat profile, suggesting other sources of organic sulphur in the peat. Substantial amounts of elemental sulphur are observed in some peat-forming systems[5], but virtually none in coal[1]. The elemental sulphur is probably of microbial origin[8].

To test the idea that elemental sulphur serves as a source of organic sulphur in peat, and hence coal, low sulphur peat (0.10%) from the Okenfenokee Swamp was fractionated to produce humic acids. Humic acids were chosen for the reaction since they are recognised progenitors of some of the more important macerals in coal and the organic sulphur of coal is associated with the maceral assemblage. A 1-g aliquot of the prepared humic acid was placed in a round bottom flask and 100 ml of chloroform and 5 μCi of ^{35}S were added to each flask. The contents of the flasks were refluxed for 6 to 48 h, then cooled, filtered and rinsed thoroughly with chloroform and then 1M HCl (chloroform removed any unreacted elemental sulphur, and the HCl dissolved any FeS that may have formed). The total ^{35}sulphur and inorganic ^{35}sulphur were determined using the Johnson–Nishita procedure[9] as modified by us[5,6], and organic ^{35}sulphur by difference. For total sulphur analysis, all the sample sulphur was oxidised to sulphate, and then the oxidised sample was placed on a Johnson–Nishita apparatus; the sulphur in the sample was subsequently reduced to H_2S via a HI-reducing solution; the H_2S was then carried via nitrogen into a zinc/sodium acetate solution, where the ^{35}sulphur became bound as $Zn^{35}S$. An aliquot of this solution was mixed with Insta-Gel and counted in a Packard liquid scintillation counter. For the analysis of inorganic sulphur, the oxidation step, in the sample preparation, was omitted; organic sulphur was determined by difference. It should be noted that any adsorbed sulphur would be detected in the analysis used for inorganic sulphur.

When ^{35}S was allowed to react with the prepared humic acid fraction there was a near linear increase in the organic sulphur content of the humic acid, as a function of time (Fig.1). The conditions of the experiment were mild enough and the chemical reactants were appropriate enough to warrant serious consideration of this reaction as a potentially important source for some of the organic sulphur found in coal. The exact chemical mode of incorporation of elemental sulphur into humic acid is

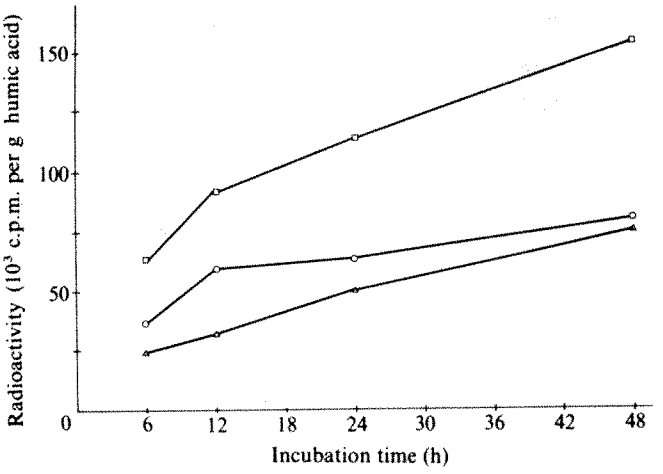

Fig. 1 Uptake of elemental sulphur in the humic acid fraction of Okefenokee peat. □, Total sulphur; ○, inorganic sulphur; △, organic sulphur.

not clear. Sulphur associated with humic acids in marine environments has been shown to be isotopically light, suggesting a microbial origin[8,10]. Elemental sulphur in sediments is thought to originate from the microbial oxidation of H_2S, and H_2S is known to originate from the microbial use of sulphate as a terminal hydrogen acceptor[8,11].

Further evidence of interactions of elemental sulphur with the organic matter in peat comes from the findings that elemental sulphur will react with certain amino acids[12], cholesterol[13] and ethyl benzene[14] to produce organic sulphur compounds. However, in all these cases, reactions were carried out at temperatures at 130 °C or above; in some cases, closed tube conditions with the addition of oxygen and catalysts were used. At these temperatures it is possible that H_2S was formed and hence was the actual reactant chemical as opposed to the original elemental sulphur. Experiments performed in the present study more closely approximate the environmental conditions that elemental sulphur and peat are subjected to in their diagenetic and metamorphic routes to coalification. The exact mechanism for the reaction of elemental sulphur with peat is not known—many carbonium ion and free radical mechanisms are possible, even at the relatively low temperatures of this experiment[15].

We thank Dr Arnold Friedman (Argonne National Laboratory) for his assistance and for reviewing the manuscript, and Dr Peter Gunther and Mr John Eadie for assistance in the field. H_2S incorporation in coal precursors: origins of organic sulphur in coal

D. J. Casagrande*, G. Idowu, A. Friedman, P. Rickert, K. Siefert & D. Schlenz

Governors State University, College of Arts and Sciences, Park Forest South, Illinois 60466

Of the forms of sulphur in coal—organic, pyrite, and sulphate—the organic sulphur component is the most difficult to remove before coal can be used. Organic sulphur, which is generally regarded as sulphur in a carbon–sulphur linkage, can represent >50% of the total sulphur found in some coals[1]. We describe here an investigation into the origin of the organic sulphur in the coal-forming sequence which includes: peat → lignite → bituminous coal → anthracite coal. Because of the chemical heterogeneity and associated chemical complexity of working with either bituminous or anthracite coals, the earliest stage of coal formation, that is the peat-forming stage, was studied. Modern progenitors of coal from the Okefenokee Swamp were studied, as these peat-forming systems closely approximate ancient systems that eventually gave rise to huge coal deposits[2–4]. While amino acid sulphur from source plants is an important progenitor of organic sulphur in peat, it was found that H_2S can react with the organic matter in peat to produce organic sulphur—a source of organic sulphur in coal that has not been previously discussed.

The peat-forming stage is a crucial time for sulphur incorporation in the coal-forming process; virtually all of the organic and pyritic sulphur in high and low sulphur coals can be accounted for at this stage[5,6]. Modern peat-forming systems, such as the marine-derived mangrove peats in the Florida Everglades, can contain as much as 10% total sulphur, of which 30–50% is organic sulphur. Sulphur must accumulate in peat as its content is sometimes an order of magnitude higher than that found in associated plants. Sulphur-containing amino acids, such as cysteine, methionine and cystine, found in both higher plants (source materials for the peat) and microorganisms (degraders of the peat), have been viewed as the source of organic sulphur found in coal[6]. Analysis of sulphur-containing amino acids in mangrove-derived peats shows that only 20–40% of the organic sulphur in peat is present as sulphur incorporated in amino acids[7,8]. Thus, the source of a major portion of organic sulphur in coal formation is in the peat-forming stage, yet the origin of this organic sulphur has not been fully explained. In walks through the peat during a field trip, a strong smell of H_2S was common; the source of this H_2S is probably microbial. *Desulfovibrio* occurs in anoxic environments and this bacterium uses sulphate as a terminal hydrogen acceptor, producing H_2S during the process[9]. In a series of experiments in our laboratory it was observed that as much as 4 mg S per kg wet peat per day (as H_2S) was produced from mangrove-derived peats.

These observations, and the fact that the organic sulphur increase in peat is not necessarily related to the associated source plants, caused us to design a series of experiments to evaluate the possibility that some of the organic sulphur found in coal may derive from the interaction of H_2S with the organic matter in peat. Aliquots from a large sample of an homogenised wet peat sample were placed in a series of desiccators; the atmosphere over the peats was evacuated using a water pump. The peat used in this study originated from core material in the Chesser Prairie area of the Okefenokee Swamp; it had a sulphur content of 0.25% on a dry basis. An $H_2^{35}S$ generating system was constructed that allowed an $H_2^{35}S/N_2$ atmosphere to be introduced over each peat sample. In operation the peat was blanketed in the desiccators with a $H_2^{35}S/N_2$ atmosphere as follows:

Table 1 The distribution of labelled organic sulphur in organic peat fractions

Time (h)	Water soluble	Benzene/methanol	Humin	Humic acid	Fulvic acid
72	5.64	—	81.84	12.03	0.49
168	3.90	0.007	40.84	55.10	0.16
504	1.08	0.14	7.59	90.65	0.44
840	1.00	0.11	25.19	73.63	0.04
Mean	2.90	0.09	38.86	57.85	0.28

(1) $Na_2^{35}S$ was put into a two neck round bottom flask, which had one side adapted for the introduction of H_3PO_4 and the other side adapted for a gas inlet/outlet; (2) the system was purged with N_2 gas; (3) H_3PO_4 was introduced on top of the $Na_2^{35}S$; (4) the entire system was closed to allow for $H_2^{35}S$ build-up; (5) stopcocks were opened that would allow for the passage of nitrogen though the $H_2^{35}S$ generating chamber and conduction of the $H_2^{35}S/N_2$ mixture into the previously evacuated desiccators; and (6) the desiccator atmosphere was filled with N_2 until ambient pressure was reached.

After various intervals (72–840 h) an individual desiccator was opened and the peat was fractionated into five components; water soluble, benzene/methanol soluble, fulvic acid, humic acid and humin. Each fraction was then analysed for both total and inorganic labelled sulphur. Note that the procedure used to analyse inorganic sulphur would also measure any hydrogen ^{35}sulphide that was adsorbed along with any elemental ^{35}sulphur, ^{35}sulphate, ^{35}sulphides, ester ^{35}sulphate, and so on, but does not measure carbon bonded (organic) ^{35}sulphur. Thus organic ^{35}sulphur[10] was calculated as the difference between total ^{35}sulphur and inorganic ^{35}sulphur.

Table 1 shows the percentage of total organic ^{35}sulphur activity in the peat as a function of organic fraction and as a function of time. There are several interesting points: (1) H_2S reacts with peat to produce organic sulphur; (2) H_2S is incorporated into the organic sulphur fraction at room temperature and it occurs in a relatively short period of time—compatible with diagenetic processes occurring in modern organic sediments; (3) the humic acid fraction—an important precursor to coal maceral(s)—shows the largest amount of organic sulphur incorporation, even though it represents <20% of the total organic matter in peat; (4) the humin fraction, which represents 70% of the total organic matter, has an average of only 38.8% of the total organic sulphur associated with it; (5) there is little organic sulphur incorporation into the water soluble fraction—the water soluble fraction represents a pool of 'free constituents' which should be available for reaction; (6) little organic sulphur incorporation is found in the fulvic acid fraction—previous studies have shown that 75% of the sulphur associated with the fulvic acid fraction is in the form of ester-sulphate[8]. A plot of the uptake of $H_2^{35}S$ as organic sulphur in the humic acid fraction, showed monotonic production of organic sulphur in the organic matter as a function of time.

The chemical nature of the bonding involved in the reaction of H_2S with organic matter is difficult to assess. It is possible that H_2S is converted to another species, which is the reactive agent[11–13]. However, there are reports which demonstrate H_2S incorporation in (1) petroleum[14], (2) organics in natural waters[15], (3) non-sulphur-containing amino acids[16] and (4) unsaturated fatty acids[17]. Also, Kaplan and co-workers have indicated that the sulphur associated with marine-derived humic acids is isotopically light sulphur which is microbially-derived[18]. The present study certainly supports this view and points to at least one of the microbially-derived sources for some of the organic sulphur in coal. The study also shows that important premaceral materials, such as humic acids, obtain an organic sulphur component at a very early point in their diagenetic history from a source that is not originally carbon-bonded. Finally, the importance of this type of reaction in the overall biogeochemical cycle of sulphur needs further investigation.

We thank Dr Peter Gunther for field assistance and John Eadie for logistic support. This work was supported by NSF grant EAR 76-84069, Governors State University, and Division of Basic Energy Sciences of the United States Department of Energy.

Are solar spectral variations a drive for climatic change?

James B. Pollack, William J. Borucki & Owen B. Toon

Space Science Division, NASA Ames Research Center, Moffett Field, California 94035

Observations of the Sun from satellite and rocket platforms have provided good evidence that solar radiation varies noticeably in the UV portion of the spectrum over a solar rotation period of 27 d[1,2]. There is also less conclusive evidence for such variations on the time scale of the 11-yr sunspot cycle[1,2]. We investigate here the possible effects of these UV variations on atmospheric ozone content and climate for time scales encompassing the 27-d solar rotation period, the sunspot period, twice this period (solar magnetic period) and much longer times. We conclude that (1) solar UV variations on time scales of weeks to months can occasionally perturb total ozone and stratospheric temperatures by noticeable amounts, but they result in only very minor changes in the troposphere; (2) the above cited estimates of UV variation over the 11-yr solar cycle are inconsistent with measured changes in total ozone; (3) with UV variations being limited by long-term trends in total ozone, only very small variations in surface temperature are expected over the 11-yr solar cycle, but possibly significant ones could occur over the 22-yr cycle; (4) solar spectral changes might be partially responsible for century-long variations in climate, which have been empirically correlated with changes in solar activity[3,4].

To distinguish clearly the solar spectral change mechanism for climate modification from ones involving luminosity changes, we alter the visible spectrum slightly ($\lesssim$ few tenths %) so that the integrated solar radiant output is an invariant. We note that very severe upper bounds (0.03%) have been placed on the variation of the solar constant on time scales of months[5], despite the occurrence of measurable UV variations on this same time scale[1,2]. Somewhat larger upper limits have been set on the change in solar luminosity between 1969 and 1976 (0.15%) (ref. 6) and from 1923 to 1952 (0.17%) (ref. 7).

Our studies of the relationship between solar UV variations and atmospheric ozone content and atmospheric temperatures differ from others[8-10] in that we estimate the impact of such variations on tropospheric temperatures, we hold the total luminosity constant, and we examine the dependence of the ozone variations on the forcing period.

The calculations were performed with a three-step iterative procedure for UV variations having a period long compared with the time required for the ozone profile to reach a steady-state solution (~1 yr). First, a one-dimensional time-marching photochemical model with vertical transport and a fixed temperature profile was used to determine the temporal variation of the ozone and nitrogen dioxide concentrations from the ground to 120 km altitude[11]. Next, the results of the photochemical calculations were used in a numerically accurate, vertically inhomogeneous, multiple scattering computer program to determine the globally averaged, solar energy deposition profile[12]. Finally, this profile was incorporated into a one-dimensional radiative–convective equilibrium program to evaluate the globally averaged temperature structure[13]. Because of the temperature dependence of the photochemical rate coefficients, we repeated the three-step calculations several times, with the temperature estimates obtained from the third step used as starting conditions.

A different procedure was followed for UV variations having a period less than the ozone relaxation time scale. In such cases the driving period is much smaller than the thermal inertia time constant for the land–ocean–troposphere system (~5 yr (ref. 14)). Thus, little change in tropospheric or surface temperatures will occur. For these cases, we used the same one-dimensional time-marching photochemical model, but with a parameterised radiative cooling and heating capability that provided estimates of temperature perturbations in the stratosphere and mesosphere[15].

As we neglect a large number of feedback processes that could alter the final answer[16], our results should be viewed simply as an exploratory study of the sensitivity of the Earth's climate to solar spectral variations. For example, we do not attempt to vary the properties of tropospheric water clouds in response to the UV ozone and temperature changes nor do we allow for dynamical effects.

There are two mechanisms that might cause solar UV variations, each being possibly pertinent for different time periods. One manifestation of solar activity is a region called a plage that covers a small fraction of the surface and is hotter than the rest of the Sun at the same altitude[17]. Because the spectral irradiance in the UV is on the Wien tail of the black-body function, much larger variations can occur in the UV than in the visible due to changes in the area covered by plages. We model this situation—essentially the sum of two black-body functions—by setting the fractional change in the UV spectral irradiance equal to $C \exp(-b(1/\lambda_0 - 1/\lambda)) \sin(2\pi t/P)$, in accord with available broad band observations of solar UV variations over a solar rotation period[1,2] where C and b are constants; λ and λ_0 are wavelength and a reference wavelength (0.175 μm), respectively; and t and P are the time and period, respectively.

The increase of temperature with altitude above the solar photosphere is thought to be due to the upward propagation of energy (such as acoustical waves) from the solar convection zone that is located right below the photosphere[18]. Conceivably, on long time scales (> yr), solar activity variations may be accompanied within the convection zone by variations in the division of the net solar flux between radiative and turbulent net fluxes. If so, alterations in the vertical solar temperature structure, particularly near the solar temperature minimum and at higher altitudes, may occur, without there necessarily being a change in the solar luminosity. Both because UV irradiance is produced near the temperature minimum and because it is situated on the Wien tail of the black-body function, such alterations of temperature structure would preferentially affect the UV output, with the magnitude of the spectral variation depending on the altitude from which the irradiance originates. We model this situation by setting the fractional variation of UV irradiance equal to $C' \exp(-b'(T_\lambda - T_{\lambda_0})) \sin(2\pi t/P)$, in accord with limited observations over the 11-yr solar cycle[1,2] where C' and b' are constants and T_λ and T_{λ_0} (4,750 K) are the brightness temperatures of the Sun at wavelengths λ and λ_0, respectively.

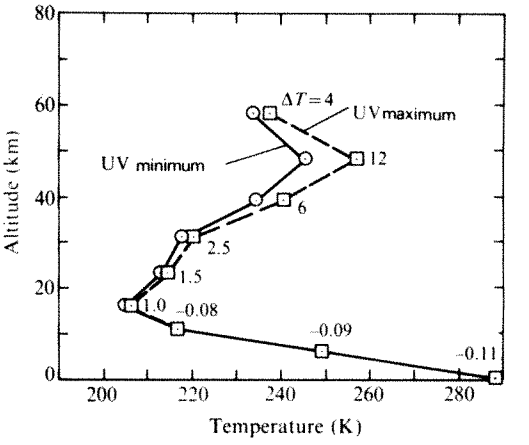

Fig. 1 Steady-state temperature profiles for times of UV maximum and minimum for long period perturbations (≫10 yr). Also shown are the temperature differences, ΔT, between these two cases.

The above alterations of the monochromatic solar fluxes were done only at wavelengths shorter than 0.29 μm, while the fluxes at longer wavelengths were altered uniformly in the opposite direction to hold the total luminosity constant. A value of 0.29 μm for the transition wavelength was selected as UV variations shortward of 0.29 μm have been reported[1,2], while severe limits have been placed on variations at visible wavelengths[7].

We have carried out a series of calculations with the brightness temperature parameterisation of the spectral variations and with C' and b' chosen to generate UV variations consistent with the reported 11-yr variations[2] ($C' = 0.4$; $b' = 0.02$). For UV variations having periods >1 yr, calculated peak-to-peak changes in ozone column density closely approach an asymptotic limit. Periods of 27 days and 6 months are characterised by peak-to-peak changes that equal about one-third and two-thirds of this asymptotic limit, respectively. Vertical transport limits the response of the system over these short time scales. We obtained very similar variations in ozone amount when the wavelength parameterisation was used and when the ratio of the amplitudes of the UV variation at 0.29 μm and 0.175 μm was varied by varying b', but the amplitude at 0.175 μm (C') was held fixed.

The solar energy deposition profile is influenced by changes both in the trace gas constituents and in the solar spectrum. For all the driving periods considered, UV minimum is characterised by a smaller amount of energy absorbed in the stratosphere, a higher global albedo, and a larger energy deposition below the tropopause. Decreases in the ozone column density and the UV flux are responsible for these trends. Some of the sunlight not absorbed in the stratosphere during UV minimum is Rayleigh scattered back to space—hence the higher albedo—while the remainder is transmitted to the troposphere—hence higher deposition below the tropopause.

Figure 1 shows the radiative–convective equilibrium temperature profiles at times of UV minimum and maximum flux for the longest period cycles (≫10 yr). As might have been anticipated from the above discussion of solar energy deposition, the stratospheric temperatures increase from UV minimum to maximum, with the largest changes occurring near the stratopause. However, the tropospheric temperatures decrease, with the surface being about 0.1 K cooler during UV maximum.

Table 1 Predicted changes in atmospheric parameters due to solar spectral variations¶

Period	Epoch	Constraint* (refs)	ΔUV*	ΔO_3^*	δT^*_{strat} (K)	δT^*_{surf} (K)	ΔS^*_{trop}

† Close to sunspot maximum.
‡ Close to sunspot minimum.
§ Time of the Maunder sunspot minimum.
‖ These values are upper bounds.
¶ In all cases, the ratio of the fractional change in irradiance at 0.175 μm to that at 0.29 μm has been set equal to 5, in accord with refs 1, 2.
We require a larger UV flux at the time of the Maunder sunspot minimum.

Evidently, the increase in downward directed thermal radiation from the stratosphere between UV minimum and maximum, due to the increase in ozone and the higher stratospheric temperatures, is less important for the tropospheric heat balance than the decrease in solar energy deposition below the tropopause. For the 11-yr period, the temperature changes in the troposphere will be only about half of their values for the longer period cases because the response time of the ocean–land–atmosphere system is comparable to the half period of the 11-yr solar cycle[14]. Correspondingly smaller responses characterise the shorter period cases. The computed changes in temperature structure are insensitive to the functional form chosen for the spectral variations, but they are sensitive to both the amplitude of the UV variation at 0.175 μm and the ratio of the amplitudes at 0.29 and 0.175 μm.

To assess the significance of changes in climate induced by solar spectral variations, we introduce the following parameters: δT_{strat}, δT_{surf}, which are the difference in stratopause (~48 km) temperature and surface temperature, respectively, between times of UV maximum and minimum, while ΔS_{trop}, ΔO_3 and ΔUV are the corresponding differences in solar energy deposited below the tropopause, ozone column density and solar UV intensity at 0.175 μm, respectively, divided by the values of these quantities at UV minimum. Table 1 summarises our estimates of these parameters for periods of spectral variation ranging from the 27-day solar rotation period to a century. In each case, an observed value of ΔUV, ΔO_3, or δT_{surf}, as indicated by the 'constraint' column, has been used in conjunction with our model calculations to estimate the values of the remaining four parameters. Table 1 also shows our crude estimates of threshold values for the various parameters, below which a predicted variation would be small compared with known changes in its value. The threshold value is set at a quarter of the known change. The peak-to-peak variations associated with the quasi-biennial oscillation were used to derive the threshold values for δT_{strat} and ΔO_3 (refs 19, 20). Threshold values of ΔS_{trop} and δT_{surf} were obtained from a tidal theory for planetary waves[21], and the globally averaged change in surface temperature over the past several decades[22], respectively.

For changes occurring on time scales of weeks, good correlations have been obtained between solar activity indices and tropospheric circulation parameters[23]. However, the reality of this solar–terrestrial relationship has been challenged because the above correlation is sensitive to which months are included in the analysis[24]; no significant correlation is obtained for some epochs[24,25]; and power spectral analyses of key meteorological variables fail to show a significant peak near 27 days[26]. Since solar UV variations may represent the most energetically important short-term modulation of solar output, it is of interest to estimate the impact of these variations on weather phenomena. As Table 1 shows measured values of ΔUV associated with the 27-day solar rotation are not expected to have caused significant alterations to any of the key atmospheric parameters, with the possible exception of a marginally significant alteration of the ozone column density.

For changes occurring on a somewhat longer time scale, a statistically significant correlation has been found between monthly averaged global ozone amount and solar activity indices[27,28]. The maximum value of ΔO_3 was found to be 0.013, with a characteristic period of about 6 months. According to Table 1, about a threefold increase in ΔUV over the 27-day value is required to achieve this ΔO_3. Even in this case, no significant alteration of the tropospheric parameters δT_{surf} and ΔS_{trop} results. However, small, but significant, changes occur in the stratospheric parameters δT_{strat} and ΔO_3, which could conceivably induce marginal effects in the troposphere through stratospheric–tropospheric coupling processes[29]. We conclude that, at best, UV spectral variations having time scales of weeks to months may occasionally perturb tropospheric weather in a barely noticeable manner.

From comparisons of measurements of solar UV irradiance made by similar broad band photometers carried on rockets and satellites, it has been suggested that the UV irradiance increased significantly from 1966 to 1970, with ΔUV ≅ 1.5 (ref. 2): 1966 was close to sunspot minimum and 1970 was close to sunspot maximum. Similar comparison of data obtained by satellite-borne spectrometers imply a decrease in UV irradiance between 1970 and 1975 of about the same magnitude[2]. Some support for the validity of these estimates of ΔUV for the 11-yr sunspot cycle is given by an apparent agreement between observed ozone and temperature variations in the middle stratosphere during the late 1960s and early 1970s and predicted changes based on these ΔUV estimates[30]. However, there are large error bars associated with this climate data set and it spans only about one sunspot cycle.

Consequently, we have examined additional data to assess further the accuracy of the above values of ΔUV for the 11-yr sunspot cycle. Estimates of the change in average ozone column density[19] for the Northern Hemisphere that cover the actual times of the solar irradiance measurements imply ΔUV ≅ 0.4 and not 1.5 (Table 1). This disagreement is much larger than would be expected on the basis of the error bars assigned to the average ozone column densities. A slightly larger discrepancy results when the less well determined globally average ozone densities are used. Furthermore, the failure of the average ozone

column densities for the Northern Hemisphere and the world to increase from sunspot minimum in 1964 to sunspot maximum in 1958 raises some doubts as to whether the later variance (1964–75) is dominated by an 11-yr period. Also, much smaller changes in middle and upper stratospheric temperatures occurred over the time period of the first set of solar UV measurements (1966–70) than expected on the basis of the claimed UV variation and much smaller temperature changes occurred in the upper stratosphere over the interval of the second set[20,31]. The ΔUV values given by Heath and Thekaekara[2] for the 11-yr solar cycle are, therefore, probably large overestimates of the true variation. According to Table 1, if all the variance in the average ozone column density between 1966 and 1970 and between 1970 and 1975 is ascribed to 11-yr UV variability, then significant changes in δT_{strat} and ΔO_3 result, but insignificant changes in δT_{surf} occur.

There seems to be a 22-yr periodicity in certain climate phenomena, such as the recurring drought on the high plains of the US[32] and in other climate indicators[33]. The time variation of average ozone densities between 1958 and 1976 may be dominated by a 22-yr period rather than an 11-yr period[19]. If all the variance in ozone amount between 1958 and 1969 is ascribed to 22-yr solar UV variation, then large changes in δT_{strat} result as well as a possibly significant variation in δT_{surf}. Conceivably, this value of δT_{surf} is large enough to account for the above cited 22-year climate changes.

Strong correlations have been shown to exist between century-long times of anomalous solar activity and climate anomalies, with periods of low solar activity corresponding to colder epochs[3,4]. According to Table 1, if all the observed δT_{surf} for a period encompassing the Maunder sunspot minimum is ascribed to solar spectral variations, very sizeable changes in all the key variables result. It is reasonable to ascribe at least some fraction of δT_{surf} to this mechanism in view of the observed changes in the structure of the uppermost regions of the Sun associated with the Maunder minimum[3,4]. Finally, aside from the significant temperature perturbations perhaps associated with longer term solar spectral variability, biologically significant changes in ozone amount also seem to be implied.

We thank Don Wiedman, Ken Bilski, and Henry Woodward for their help with the calculations.

Neogene explosive volcanicity, temperature and glaciation

J. R. Bray

PO Box 494, Nelson, New Zealand

Recent theoretical[1–6] and observational[7–10] demonstrations of depression in surface temperature of the Earth due to explosive volcanic eruptions have provided a more exact basis for speculations that explosive volcanicity may have had a climatic impact[11–15] during periods over the past 2 Myr. In this letter, broad volcanic–climate relationships are assessed over a longer period by comparing the dates of global explosive phases and of volcanic–plutonic phases with paleotemperature and glaciation records from the Neogene. Analysis of these records indicates significant relationships between the explosive and volcanic–plutonic phases and Neogene temperature decline and also a correspondence between the three greatest explosive and volcanic–plutonic phases and glacial expansion. The second highest global explosive peak was coincident with recently suggested dates of around 3.2 Myr for the initiation of the late Cenozoic glacial age. Further testing of these relationships is necessary to resolve inconsistencies in the late-middle to early-late Miocene and in the late Pliocene.

To determine patterns of temperature trend for the Neogene, I examined six palaeotemperature curves[16–21] for trend during geological epochs and their subdivisions and for trend on the absolute time scale of Berggren[22]. This examination indicated that the six studies were in agreement in showing two major periods of temperature decline, the middle Miocene and the late Pliocene or early Pleistocene with two studies[16,17] also showing substantial declines, and another study[18] a minor decline in the late Miocene. There was also predominant agreement on a temperature increase during the early Miocene and the middle Pliocene. Temperature trends, using Berggren's scale[22], from Figs 5 and 6 of Kennett[16], Fig. 16 of Margolis *et al.*[17], Fig. 2 of Buchardt[18] and Fig. 4 of Savin *et al.*[19] are shown in Table 1. Results from the other two palaeotemperature studies[20,21] were not included because they were less sensitive and were repetitive of the four presented curves. Table 1 also includes estimates of the occurrence of major glacial expansion periods which included dates of 16–14 Myr (ref. 16), 5–6 Myr (refs 16, 23) and 4.7–4.3 Myr (ref. 23) for Antarctica and 16 Myr (ref. 24) for the Northern Hemisphere.

The palaeotemperature and glaciation data in Table 1 were compared with two independent estimates of Neogene volcanic patterning. The first, by Kennett *et al.*[25], was based on a Pacific Basin marine ash survey which found four major Neogene explosive episodes that occurred (in descending magnitude) in the Quaternary (2–0 Myr), the middle Miocene (16–14 Myr), the latest Miocene to early Pliocene (6–3 Myr) and the late Miocene (11–8 yr). These patterns are similar to those of a global marine ash survey conducted by the same authors[25] and summarised in their Fig. 6. The second estimate of patterning of Neogene volcanicity was based on a global literature review which I made of 1,084 exactly dated volcanic and plutonic events, both terrestrial and marine. Examination of the distribution of these events suggested that there were two major and one minor Neogene volcanic–plutonic phases (number of volcanic–plutonic events per 10^5 yr in parentheses) 3.3–0 Myr (17.7), 16.0–13.0 Myr (4.4) and 6.4–5.0 Myr (4.1) and three intervening periods of lesser volcanic–plutonic activity, 19.9–16.1 Myr (2.1), 12.9–6.5 Myr (2.7) and 4.9–3.4 Myr (3.6). Volcanic–plutonic activity peaks occurred at 19.5–19.4, 16.6–16.5,15.7–15.6, 15.2–15.0, 14.6–14.5, 13.5–13.4, 11.4–11.3, 10.0–9.8, 8.3–8.2, 6.3–6.1, 5.8–5.7, 5.1–5.0, 3.1–3.0, 2.7–2.6, 2.4–2.3, 1.9–1.8, 1.2–1.0, 0.6–0.5 and 0.3–0.1 Myr.

Explosive episodes from Kennett *et al.*[25]; volcanic–plutonic episodes from global literature survey. Glacial expansion periods as in text. Palaeotemperature trends: *a*, Kennett[16]; *b*, Margolis *et al.*[17]; *c*, Buchardt[18]; *d*, Savin *et al.*[19]. Plus indicates an increasing, and minus a decreasing global temperature.

The geological occurrence of the four explosive phases in the Quaternary, middle Miocene, latest Miocene to early Pliocene and the late Miocene, as described by Kennett *et al.*[25], overlapped the three main global temperature decline periods outlined above which occurred in the late Pliocene to early Pleistocene, middle Miocene and the late Miocene. During the two greatest explosive episodes, from 16–14 and 2–0 Myr, 14 of 16 temperature estimates showed a decline. For the moderate explosive episodes of 11–8 and 6–3 Myr, there were 17 of 24 temperature estimates that declined. In the remaining, non-explosive intervals, 21 of 40 temperature estimates showed a decline. To test the validity of these patterns, the temperature data in Table 1 were compared with the four Kennett *et al.* explosive episodes, using a fourfold contingency table. The result gave a χ^2 of 5.5 ($P < 0.02$) which suggests a connection between the occurrence of Neogene explosive episodes and a tendency towards temperature decline. A fourfold contingency χ^2 test was also applied to the volcanic phases which occurred at 16–13, 6–5 and 3–0 Myr in the global volcanic–plutonic survey and the temperature data in Table 1. The result gave a χ^2 of 8.1 ($P < 0.005$), again suggesting a Neogene volcanism–temperature relationship.

Examination of the possible volcanism–temperature relationship in Table 1 indicates an anomaly in the late Middle to early late Miocene around 14–11 Myr during which time 11 out of 12 palaeotemperature data showed a decline during a period of low explosive activity. Data in the global survey of Kennett *et al.*[25] indicate, however, that the level of ash produced in this period was only moderately less than in the preceding and succeeding explosive episodes which suggests that the trend of temperature decline which began during the early middle Miocene may have been sustained by the moderate activity from 14 to 11 Myr.

There was a correspondence in Table 1 between the major Neogene glacial expansion periods at 16–14, 6–4 and 2–0 Myr and both the three highest Neogene explosive episodes and the three volcanic–plutonic phases. The apparent lack of a major glacial expansion at the explosive episode around 11–8 Myr could relate to the explosive level during this interval which had the lowest activity of the four Neogene episodes designated by Kennett *et al.*[25].

The second highest Neogene explosive peak in Kennett *et al.*[25] (Fig. 2) was from 3.5 to 3.0 Myr. Kennett *et al.*[25] in noting this secondary explosive peak stated that there were also many lavas of this age in the circum-Pacific, but that there were not enough data to determine whether this 3.5–3.0 Myr peak was distinct from, or part of, the explosive episode from 6 to 3 Myr. The peak around 3.5–3.0 Myr is also present in a global survey of volcanic–plutonic activity which I have made and in local explosive studies including a well-dated upswing which began between 3.2 and 3.1 Myr in Japan[26]. This major explosive peak from around 3.5–3.0 Myr was concurrent with an extensive and globally well-distributed array of estimates of major temperature decline around 3.2–3.1 Myr (refs 26–30) and glacial expansion around 3.5–3.1 Myr (refs 31–35) which are currently regarded[28] as the date for the initiation of the late Cenozoic glacial age.

From around 3.0 Myr to the present, the global explosive data[25] show a period of low output from 3.0 to 2.0 Myr and then a maximum activity from 2.0 to 0 Myr. As the climatic data suggest that there was a period of cooler temperatures and cyclic glacial expansions from around 3.2 to the present[28], the low global volcanic record from 3.0 to 2.0 Myr may contradict the volcanic climatic hypothesis. Regional studies[36–38] from ocean cores in the North Pacific indicate, however, that there was a generally high level of explosive activity during the 3.0–2.0 Myr interval with a major pulse around 2.5–2.3 Myr. Further and more sensitive dating of the global explosive data may resolve this inconsistency.

The Neogene volcanism–climate relationships shown above were assessed under the assumption that it is the total level of explosive activity that may have had a climatic impact. It is conceivable, however, that a relatively few single or closely spaced massive eruptions could have acted as trigger devices[39] for the 'instantaneous glaciation' mechanism and that it is the occurrence of these massive eruptions which is climatically significant. This possibility is not contradicted by the demonstrated correspondence between the Neogene explosive episodes, when massive eruptions more likely occurred, and the climatic parameters in Table 1.

Since writing the above, I received a manuscript from Kennett[40] which has conclusions broadly similar to those presented here, and includes the statement that the four explosive phases outlined in Kennett *et al.*[25] coincide with "critical developments in the climatic and glacial evolution of the earth".

India's and Australia's pole path since the late Mesozoic and the India–Asia collision

Chris T. Klootwijk

Research School of Earth Sciences, Australian National University, PO Box 4, Canberra ACT 2600, Australia

John W. Peirce

Petro Canada, PO Box 2844, Calgary, Alberta, Canada

The Indian apparent polar wandering path (APW) for the late Mesozoic–Cenozoic period has been too poorly defined to use as a constraint to establish the timing of collision of India and Asia. Here we update the Indian APW on the basis of new palaeomagnetic data from DSDP cores and from Baluchistan (Pakistan). This new synthesis details the late Mesozoic and Cenozoic northward motion of India, and supports geological evidence for an initial collision with Asia during the late Palaeocene–early Eocene.

Recent attempts to trace India's northward motion and collision with Asia have used two approaches. Seafloor spreading data from the Atlantic and Indian Oceans were used to detail the relative Indian–Eurasian motion[1]. According to this rather generalised approach intimate contact between the two continental masses was established by Eocene–Oligocene time (~40 Myr), based on a reduction in the rate of relative motion from an initial 10 to 16 cm yr^{-1} to about 5 cm yr^{-1}.

On the other hand, using the relative motion data of the Indian, Australian and Antarctic plates[2–4] to reconstruct the Indian–Australian relative motion and the Australian APW[5–7] for positioning the Indian plate relative to the pole, others have argued[8,10] that initial collision occurred during late Palaeocene–early Eocene time (~55 Myr; ref. 9). India's northward motion reduced at that time from 15–20 cm yr^{-1} to <4–6 cm yr^{-1}, which supports earlier advanced geological arguments[10] for a pre-Middle Eocene timing of collision.

The DSDP pole positions[11] were obtained as 10 Myr averages of individual pole positions, determined from (1) mean palaeolatitudes at a given site and at a given age corrected for a systematic downwards deflection due to absence of declination control[12,13] and from (2) declinations at a given site and at a given age simulated[11] from seafloor spreading data as summarised by Powell *et al.*[14] The Baluchistan data in part come from an allochthonous structural unit, but results have been corrected for a well determinable clockwise rotation[15].

This new Indian APW (Fig. 1) facilitates direct tracing of India's northward movement (Fig. 2*a*). New palaeomagnetic data from Ladakh (north-west Himalaya[16]), north of the Indus–Tsangpo suture zone, have established the palaeoposition of the Ladakh segment of the Kohistan–Ladakh island arc (Fig. 2*b*, refs 17, 18) before collision and during cooling (K–Ar ages 45–49 Myr, see ref. 16) after its collision with northward-moving continental Indo–Pakistan. Comparison of Fig. 2*a* with 2*b* evidently supports the postulated pre-Middle Eocene data of collision[8,10]. On the basis of geological evidence from north-western Indo–Pakistan this postulation can now be refined as initial collision between continental Indo-Pakistan and an island arc off southern Asia, which occurred most probably during the late Palaeocene–early Eocene[9,11,16,19,20].

The former southern boundary of Asia, juxtaposed to India, is not well defined, but can be taken as the eastwards continuation of the Zagros–Makran convergence zone[9]. The 2–10 °N palaeolatitude of the Ladakh segment of the Kohistan–Ladakh island arc before and on initial collision, is far to the south of the contemporaneous position of this extrapolated Zagros–Makran convergence zone relocated according to Eurasian palaeomagnetic data[21]. Closure of a hypothesised marginal basin along the further northwards positioned Shyok zone[17] can possibly be related to a reduction in the rate of the Indian–Eurasian relative movement at the Eocene–Oligocene time boundary as interpreted elsewhere[1,12].

Relocation of India according to Australian palaeomagnetic data and plate relative movement, disagrees (but just not significantly at the 95% level) for at least the early Tertiary period (Fig. 2*c*) with direct palaeolatitudinal observations from the Indian plate (Fig. 2*a*) and from Ladakh (Fig. 2*b*). India's indirectly obtained palaeoposition according to the Australian Barrington Volcano result (Fig. 2*c*; 52 Myr) is about 1,000 km further north than its directly observed position at the time of initial collision. The DSDP core data from the Indian plate and the results from Ladakh are in mutual agreement for the early Tertiary. Therefore, the above discrepancy has to be explained either by an error in the relative-motion data or by an inaccuracy in the Australian APW. The scale of the discrepancy seems beyond that which it is reasonable to expect in the relative motion data. One of us (J.W.P.)[12] previously indicated that an age of the Barrington Volcano about 10 Myr younger than the determined 51.7±0.7 Myr (ref. 5) would resolve the discrepancy. K–Ar ages as young as 43 Myr were reported for this volcano, but were not considered to have significant bearing on the age of the palaeomagnetically studied flows (ref. 5 and I. McDougall, personal communication). Therefore, the dis-

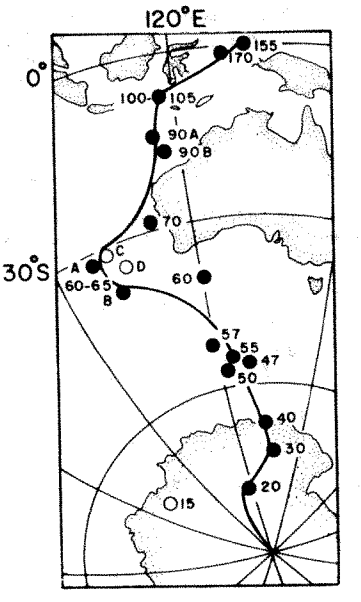

Fig. 1 APW for India based on data from continental Indo-Pakistan and DSDP core data from the Indian plate (Table 1). The ages indicated represent radiometric ages or the mean of stratigraphic age ranges as used in the determination of transferred pole positions (Table 1, Fig. 3*a*). ○ The Murree–Siwalik pole position[22] from the allochthonous Salt Range–Potwar Plateau structural unit, and the pole positions from the Lower and Upper Deccan Trap successions (60–65 C and D respectively) determined from maximum grouping of a density distribution of individual poles[11] as alternatives to Fisherian mean pole positions (60–65 A and B, respectively). Linear polar projection.

† Finite rotations for the Australia–Antarctica motion were according to the summary in ref. 31 for the period up to 45 Myr BP, and according to ref. 32 for reconstruction of the initial fit.

Myr BP	Lat (°N)	Long (°E)	Angle (°)
10	9.7	36.5	−6.75
21	13.8	34.6	−12.0
29	14.25	33.25	−16.0
35	12.5	34.4	−18.9
45	10.3	34.75	−23.6
>50	11.9	30.8	−30.9

Eulerian rotation poles for the India–Antarctica motions were according to the summary in ref. 3 (fixed to Antarctica).

Myr BP	Lat (°N)	Long (°E)	Angle (°)
0–32	4.9	36.4	18.3
32–53	−16.0	27.4	18.4
53–64	4.0	−3.0	15.6
64–80	−2.0	8.0	25.24
80–130	12.29	144.20	−21.85

‡ The errors (α_{95}) refer to the 95% confidence limits of the original pole position only, and do not include estimates of the errors in the finite rotations.
§ Results corrected for an inferred clockwise rotation of the Sulaiman Lobe over 50°.
‖ Mean result obtained from density distribution of palaeomagnetic pole positions[11].
¶ The Salt Range-Potwar Plateau Unit is most probably an allochthon, detached from basement[11].

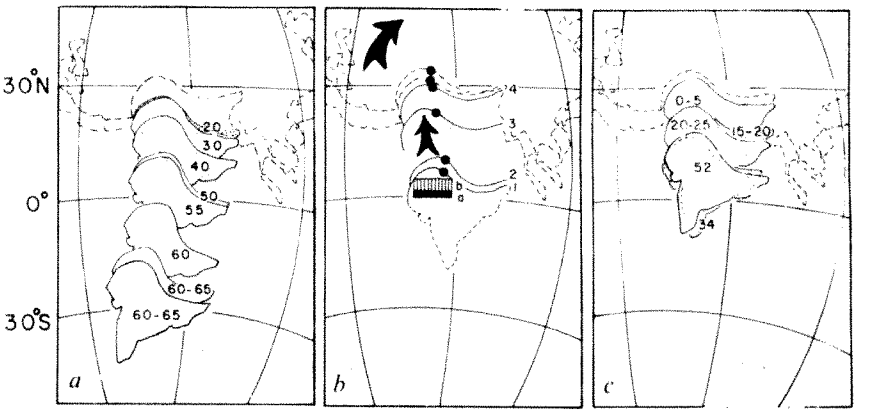

Fig. 2 Successive palaeolatitudinal positions of India according to pole positions from the Indian plate (Fig. 2*a*) and transferred pole positions from Australia (Fig. 2*c*). Note the discrepancy between India's palaeoposition according to the transferred Barrington Volcano pole position (Fig. 2*c*; 52) and the palaeopositions according to Indian data of comparable age (Fig. 2*a*; 50, 55). India's northern boundary is drawn along the Indus–Tsangpo suture zone and its western and eastern continuation. Figure 2*b* shows the palaeolatitudinal position of the Ladakh segment (large dots) of the Kohistan–Ladakh island arc north of the Indus–Tsangpo suture zone, according to four magnetisation components determined[16] in the Ladakh Intrusives (1 and 2: ~50 Myr BP and postdating initial collision of continental Indo–Pakistan with the island arc; 3 and 4: younger magnetisation components probably resulting from younger phases of the Himalayan orogenesis). For enhanced visibility the Indus–Tsangpo suture zone is shown in its present form and position relative to the Ladakh region. Zone a indicates the palaeolatitudinal position of the Upper Cretaceous Dras Flyschoids outcropping within the suture zone[11], and zone b indicates the palaeolatitudinal position of the Ladakh region according to the sampled lower Tertiary to possibly Upper Cretaceous Indus Molasse which overlies the Ladakh Intrusives[11]. The present outline of southern Asia is positioned according to mean palaeomagnetic results from Eurasia[21]. *a*: –·– 60 Myr; – – – 20 Myr. *b*: –·– 50 Myr; – – – 20 Myr. c: –·– 50 Myr; – – – present day. Linear polar projection.

crepancy probably results from inaccuracy in the pole position of the Barrington Volcano.

For a further check on discrepancies between the Indian and the Australian APWs, late Cretaceous and Tertiary pole positions from the Indian plate have been transferred to the Australian plate and the alternative APW for Australia thus obtained is shown in Fig. 3*a*. In Fig. 3*b*, this indirectly obtained APW is compared with the hitherto established late Cretaceous–Tertiary APW for Australia, as compiled before from all previously available Australian palaeomagnetic data[6,7]. This zig-zag shaped direct APW for Australia (dashed line connecting squares) is either notably diplaced from the indirectly obtained APW (Fig. 3*b*, ■ 30), does not agree with it in position or age (Fig. 3*b*, ■ 50), or is not sufficiently detailed to show the pronounced 60–65 Myr kink which is present in the indirect APW. These observed discrepancies reflect possible inaccuracies in the pole positions of respectively the Barrington Volcano (Fig. 3*b*, ● 52) and the Liverpool Volcano (Fig. 3*b*, ● 34). Apart from these discrepancies most other Tertiary pole positions for Australia (Fig. 3*b*, ●s) follow the indirect APW at an only slightly westwards displaced position.

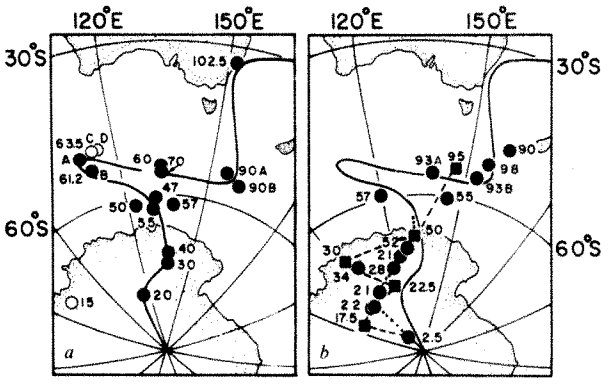

Fig. 3 *a*, The Indian APW (full line) and Indian pole positions (● and ○) transferred to Australia. *b*, Comparison of the indirectly obtained APW for Australia with an earlier compiled interpretation of Australia's APW (refs 6, 7; dashed line) and with individual Australian pole positions (●···). Compare with Fig. 1. See text for discussion and Table 1 for pole positions and confidence limits. The latter are not shown in the figures to preserve visibility. Linear polar projection. The circle (*a*, 15) indicates the transferred Indian Murree-Siwalik pole position[22]. Its quoted support[7] for the zig-zag shaped Australian APW does not seem warranted as this ill-constrained result comes from the allochthonous Salt Range–Potwar Plateau structural unit, whose rotational movement is not fully determined[11].

The indirectly obtained APW is proposed here as an alternative to the directly observed APW for Australia. The former must be considered speculative until substantiated by further (transferred) Tertiary palaeomagnetic data from continental Indo–Pakistan and corroborated by forthcoming data from Australia. Note that the zig-zag shaped direct APW for Australia is up for refinement and that previous relocations of India based on this APW can no longer be considered to be accurate. India must be positioned according to palaeomagnetic data from the Indian plate.

We thank Ian McDougall, Henry Halls, Mike McElhinny, Peter Molnar and John Sclater for helpful criticism, and Brian Embleton, John Giddings, Mart Idnurm and Phil Schmidt for discussions.

An Archaean suture in Sierra Leone?

H. R. Williams

Department of Geology, University of Leicester, UK

Considerable evidence has appeared supporting plate-tectonic mechanisms for the production of Archaean metamorphic terrains[1-4]. Windley[1] has proposed models to explain both the relationship between the high grade 'gneiss' and the low grade 'granite–greenstone' terrains and the building of continental crust by collision of small continental masses. His model uses the same geological mechanisms as those typically exhibited by Phanerozoic orogenic belts, except that they were more rapid during the Archaean as a result of the fast seafloor spreading rate at that time[5,6]. I propose here that an extensive zone of mylonites, up to 10 km thick, on the coastal margin of the West African Craton[7,8] is a suture developed during the late Archaean at the site of collision of two granitic continental masses, now preserved in a partially reworked state as the Guyana Shield and the West African Craton (Fig. 1). The suture is evidence for continental coalescence in the late Archaean.

In the vicinity of Sierra Leone the mylonite is at least 400 km long and consists of severely tectonised gneisses and mylonites nearly 10 km thick[7]. The mylonite is broadly divisible into a 5-km thick zone of fine grained mylonites of both basic and granitic composition, underlain by up to 5 km of flaggy gneisses of variable composition. The gneisses and mylonites are well banded, contain deformed and granulated augen and exhibit ribbon texture. Tectonic interleaving of the rocks on each side of the mylonite zone occurred at an early stage resulting in mixed basic and granitic gneisses and mylonites. This zone of extreme deformation is sometimes not as fully developed as suggested; in southern Sierra Leone and western Liberia, for example, the mylonites seem to be poorly developed or absent.

Structurally above and to the west of the mylonite zone is a granulite facies supracrustal belt, known as the Kasila Group[7,8], which forms a linear north-west–south-east trending intensely-deformed zone adjacent to the Liberian granite–greenstone terrain of the West African Craton (Fig. 1). Approximately 8 km of fine grained basic granulites containing subordinate banded iron formation, semi-pelites and quartzites are overlain by 5 km of amphibolite, metasedimentary granulites and migmatites. The lower part of the southwesterly dipping succession is characterised by the presence of sills of coarse-grained layered leucogabbro[7].

Structurally below and to the east of the mylonite zone is the extensive granite–greenstone terrain of the West African Craton, which typically yields radiometric ages of 2,700 Myr[9]. Consisting predominantly of granodioritic gneisses and migmatites, the terrain has a structural trend discordant with the adjacent Kasila Group and mylonite zone, being generally north–south as defined by the thin synclinorial strips of amphibolite facies supracrustals.

The thickness and longitudinal extent and the structural and metamorphic characters of the Kasila Group strongly contrast with the supracrustal greenstones of the adjacent terrain. The Archaean gneisses and granulites of the Guyana Shield, although partly reworked as a result of early Proterozoic activity[9,15] tend to be of variable structural trend and like the granite–greenstone terrain of the West African Craton contrast with the essentially linear structure and extreme metamorphic grade of the Kasila Group. Although the Kasila Group is regionally discordant with the greenstone trends in the adjacent terrain, the granitic terrain immediately adjacent to it is deformed into parallellism with the high grade belt[10,11].

Some 20 km to the east of the mylonite zone is a series of disconnected exposures of low grade recumbently folded Archaean supracrustals, known as the Marampa Group[7], with a lower contact thrust against the underlying granitic rocks. They are clearly not part of a greenstone belt structure and being allochthonous, were perhaps derived as a nappe sheet from an upper level of the adjacent Kasila Group before its extreme deformation and metamorphism.

The presence of the mylonitic thrust zone, the Marampa Group klippen, the strong contrasts in stratigraphy, structural and metamorphic styles between the Kasila Group and the adjacent terrain suggests that the two major structural units were brought together tectonically. One mechanism for the production of the observed field relations could be that of a continental collision suturing orogeny similar to that envisaged for the Dalslandian[12,13], or for the Himalayas[14]. The Kasila Group supracrustals might originally have been deposited in an intracratonic or small ocean basin between two recently stabilised granitic terrains which were then driven together through the active plate-tectonic regime that characterised the late Archaean[2,5,6]. The act of complete suturing could trap basaltic crust and supracrustals between the two masses, squeezing up some at an early stage to form the Marampa Group nappe sequence, while the remainder became steadily attenuated in a vice-like situation (Fig. 1). Closure was accompanied first by plastic deformation in granulite facies conditions and then brittle deformation in retrogressive metamorphic conditions, giving rise to a thick sequence of fine grained granulite facies rocks, underlain by thrust zones of flinty material, underlain in turn by porphyroblastic flaggy gneisses. Post-collisional deformation might have thickened the zone of suturing by shortening and duplication, during which time the Kasila Group and the immediately adjacent crust were subjected to a high-temperature metamorphism due to burial in the locally thickened crust. Subsequent isostatic rebound allowed erosional processes to unroof the suture zone as a mass of material which is of a higher grade of metamorphism than the surrounding terrain.

On a much larger scale and at a deeper level of erosion, these field relations are similar to those of the root zone to the Helvetic nappes in the Ursuren Zone between the Aar and Gotthard Massifs in the Swiss Alps. The Ursuren Zone consists of a steeply dipping body of supracrustals bounded on both sides by zones of extreme deformation in which both supracrustals and the enclosing granitic material have been subjected to a very intense shear deformation. The later stages of the Alpine orogeny apparently forced the subduction of the granitic Aar massif below that of the Gotthard massif, while the sediments that were trapped between the two became intensely deformed in the

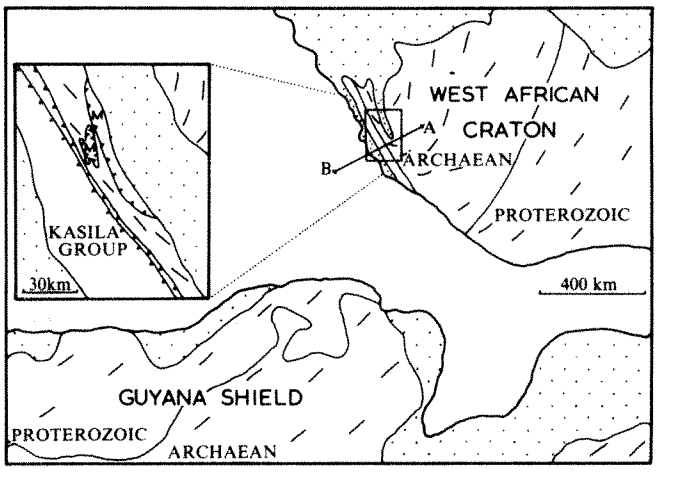

Fig. 1 Reconstruction of pre-mesozoic geology of the West African Craton and the Guyana Shield. Trend lines indicate regional structure of Archaean, much of which is partially reworked during the early Proterozoic. Post early Proterozoic cover indicated by stippling. Line A–B indicates position of idealised cross-section shown in Fig. 2. Inset shows detail of geology of western Sierra Leone, indicating the spatial relationships between the Kasila Group, the Marampa Group (M), and the thrusts and mylonites of the suture zone (thrust symbols).

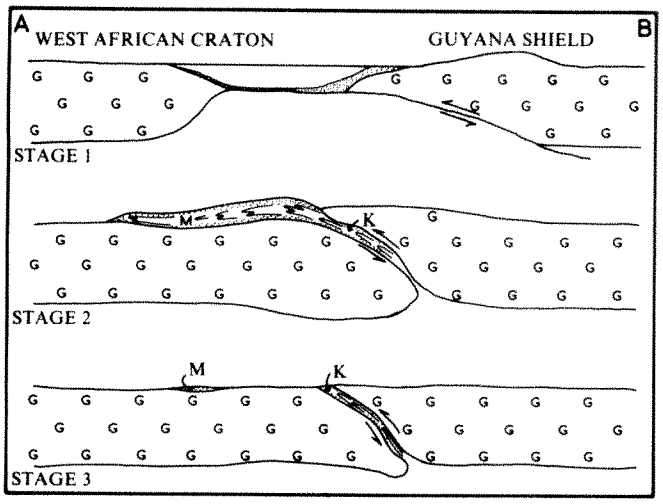

Fig. 2 Cartoon of envisaged sequence of events leading up to the formation of the Archaean suture. Stage 1, convergence of continental plates, closing of sedimentary basin floored by basaltic material. Stage 2, collision, causing plastic deformation of the Kasila Group to produce nappe sequence at high level, with granulite facies shear zones at deep level. Thickening and uprise of suture zone, overriding of the Guyana Shield onto the West African Craton. Stage 3, continued over-riding, brittle thrusting, mylonite formation in retrogressive metamorphic conditions, rapid erosion with isolation of Marampa Group as klippen.

suture zone. The granitic material on either side of the suture was also deformed, ultimately becoming schistose. If allowance has been made for the difference in scale there are strong similarities between the Cenozic Alpine and Archaean West African examples of a collisional suture.

The collision along the mylonite zone also explains the strongly developed brittle fractures in the adjacent Archaean granite–greenstone terrain of Sierra Leone[7,11]. Two main directions of fractures are obvious from the regional drainage pattern, forming a conjugate pair, one trending roughly north–south, the other east–north-east. Ideally, these two directions of fractures could be produced by a compressive stress acting from the south-west during the late Archaean suturing orogeny.

Post-Palaeozoic seafloor spreading has separated the cratonic masses which united so violently during the late Archaean, but has done so close to the line of the original suture. Kennedy[16] noticed that Pan African tectono–thermal belts tended to act as the loci for subsequent rift structures in the Mesozoic. As a result, sutures formed in early orogenic belts are susceptible to later plate activity, frequently becoming destroyed as plate-margins in orogenic belts.

If the mylonite zone and the associated high grade Kasila Group supracrustals represent a suture developed as a result of two continental masses colliding at the end of the Archaean, then it supports the opinion that primitive plate tectonic mechanisms were active in the Archaean.

Sex ratio and niche differentiation in spinach (*Spinacia oleracea* L.)

S. S. Onyekwelu* & John L. Harper

School of Plant Biology, University College of North Wales, Bangor, UK

Studies on the population biology of dioecious plants have concentrated on deviations from the expected sex ratio of 1:1 (refs 1–4) and on sexual dimorphism[5–10]. Sexual dimorphism may imply that the two sexes have different ecologies and this has been demonstrated for a number of animals[11]. Clearly, if males and females occupy at least partially different niches, competition between members of the two sexes will be reduced and observed sex ratios may be biased by the relative carrying capacities of the two niches. Putwain and Harper[12] described differences in the seasonal patterns of growth of males and females in *Rumex acetosa* and *Rumex acetosella* and Freeman *et al.*[13] showed that the males of five dioecious plant species in northern Utah were more abundant on xeric microsites, while females were over-represented in the moister regions of each local environment. We report here that the growth of male and female plants of the annual *Spinacia oleracea* L. var. Viking is affected differently by population density, and this is reflected in the sex ratio.

The experiment was carried out in the field at Pen-y-ffridd Experimental Station at Bangor, North Wales. Seed was sown on 6 June 1978 at three densities—120, 600 and 3,000 seeds per plot, 50 × 50 cm (equivalent to distances between the seeds of about 5 cm, 2 cm and 0.9 cm, respectively). There were four replicate plots at each density in a fully randomised design.

Male plants started to flower on 22 July and the first female plants did not flower until 2 weeks later. During this 2-week period the males were very conspicuous and a casual observer could easily have recorded the population as wholly composed of males. The apparent sex ratio changed considerably after 6 August as females began to flower and branch vigorously. The populations were harvested on 17 August, when several plants had still not flowered and were spindly and trailing beneath the canopy of the flowering plants. It is unlikely that any of them would have flowered if left for longer. At harvest the male, female and unflowered plants were counted. The mean percentage dead leaves per plant (a measure of the extent of senescence) and the mean number of axillary shoots per plant were determined separately for male and female plants. The number of dead male and female plants was also recorded. Table 1 shows the proportions of sown seed that formed plants present at harvest, the proportions of plants that flowered and the sex ratios of the flowering plants. The populations showed three distinct density-dependent reactions. With increasing density the proportion of seeds giving plants still present at harvest fell from 0.546 to 0.143. Of the plants that survived to harvest the proportion failing to flower increased from 0.195% to 0.318% with increasing density. Males formed an increasing fraction of the total flowering plants as density increased. At the lowest density the sex ratio did not deviate significantly from 1 : 1 but at medium and high densities there was significant deviation in favour of male plants.

There is no reason to doubt that the sex ratio was equal among the seeds sown. Of the plants that were present at harvest a sufficient number had remained vegetative or had died to account for all the deviations in the observed sex ratios.

The mean dry weight and the mean number of axillary shoots borne by females at harvest was significantly greater than that of the males at all densities (Tables 2 and 3), reflecting their

continued growth, in contrast to many of the early flowering males which were already dead at the time of harvest (Table 4). The earlier senescence of the males is shown by the proportion of dead leaves borne by the plants which was higher on male plants at all densities (Table 5).

These results show both sexual dimorphism and niche separation in time in the development of the two sexes in spinach. Males are precocious in growth and flowering time but tend to senesce and die earlier than the females which continue to grow and develop axillary branches. While the earlier flowering males are dying, most of the females are setting seeds and continuing to increase the area of leaf both on the main stem and on the new axillary shoots. The continued growth of the females may be made possible by resources (for example, light) freed by the death of male plants.

Precocious flowering and senescence of the males must imply considerable wastage of pollen. However, the early death of male plants at the time when the females are setting seed may increase the reproductive vigour of the female plants. The evolution of this type of sexual niche differentiation might be explained if the dispersal of seed and pollen is highly localised so that a male is likely to favour his own progeny by dying early.

Niche separation of sexes in space or in time is probably one of the causes of observed unbalanced sex ratios in dioecious plants. In a population where one sex flowers and dies earlier than the other, the time of observation of the sex ratio becomes critical and in the present study the observed male sex ratio changed considerably over 6 weeks. A number of deviant sex ratios have been reported in *Spinacia oleracea*. Zwaan[14] found that spinach sown in a hot and dry climate produced an excess of male plants while seed sown in the cool moist climate of Holland produced nearly equal numbers of males and females. Rosa[6] commented, however, that such tests of 'place effect' were not reliable unless the different plantings came from the same seed samples. Hoffman had observed that the sex ratios of spinach appeared to vary according to the spacing of the plants (quoted in ref. 15). When plants were crowded or more or less stunted, males predominated, but with wider spacing and better growing conditions there were relatively more females (he did not give figures). When the two sexes are ecologically different and interacting competitively it is not surprising that sex ratios are altered by changes in density. Rosa[6] grew six varieties of spinach in different conditions of nutrition, spacing, shading, date of planting and mutilation. He concluded that none of these factors had any appreciable influence on sex expression but he used a lower range of densities (interplant distances of 15, 5 and 2 cm) than in the experiment reported here.

In view of the sexual niche differentiation (the Jack Sprat effect) described here for *Spinacia*, for *Rumex* species by Putwain and Harper[12] and by Freeman *et al.*[13] it is pertinent to ask how large a role such ecological differentiation may have played in the evolution and maintenance of dioecy.

There is no reason to propose that the resource demands made in the production of male gametes are the same as those involved in producing female gametes and nurturing embryos. Certainly the time sequence of resource consumption in producing male and female gametes and mothering embryos may be very different. Populations of *S. oleracea* are strongly protandrous yet because the plants are dioecious the protandry cannot be explained as an outbreeding device. If it is interpreted as one manifestation of ecological differentiation between the sexes it raises the further question of whether protandry and protogyny in hermaphrodites are really outbreeding mechanisms or whether they represent a somewhat similarly evolved non-synchrony of demand on limiting resources but occurring, in hermaphrodites, between the two gamete types within the plant or within a flower.

S.S.C.O. acknowledges receipt of a Commonwealth Fellowship during the period when this work was done at Bangor.

Table 4 Effect of plant density on precocious death of male plants of *Spinacia oleracea*: percentage of male and female plants dead at harvest 17 August

Density	Mean (g) ♂	Mean (g) ♀	s.e. of difference between the two means	Degrees of freedom
Low	13.62	0	2.03*	6

Toad tadpoles associate preferentially with siblings

Bruce Waldman & Kraig Adler

Section of Neurobiology and Behavior, Cornell University, Langmuir Laboratory, Ithaca, New York 14850

Highly structured social systems can involve close kinship groups (eusocial insects[1], lion prides[2], helpers-at-the-nest in birds[3]). However, kinship generally has not been considered to be important or necessary for what seem to be merely gregarious phenomena, such as schooling behaviour[4]. In fact, Fisher first proposed kinship theory to explain the evolution of noxious taste in certain gregarious insect larvae. He reasoned that traits which at first may not be directly beneficial to the individual, such as distastefulness or warning coloration, might be selected for if they conferred advantage to siblings in the swarm[5]. Like some insect larvae, the tadpoles of many toads (genus *Bufo*) are conspicuously coloured, distasteful to predators and highly gregarious, forming densely packed schools in open areas along pond shores[6]. The tadpoles' aggregative behaviour may be important for feeding efficiency[7,8], thermoregulation[9] or predator deterrence[8], but their conspicuousness coupled with their distastefulness suggest that schooling may also serve an aposematic function. Consistent with the predictions of a kin selection model, we report here that tadpoles of the American toad (*Bufo americanus*) preferentially associate with siblings in laboratory conditions.

During May and June 1977, we collected amplectant pairs of toads from several breeding congregations. Each pair was held in the laboratory in a separate 10-l bucket, and most females oviposited in these buckets within 24 h. Each clutch of eggs was transferred to a separate aquarium, where tadpoles were reared on boiled spinach for about 45 d, until they reached developmental stage 35 (ref. 10). Tadpoles were then placed for 24 h in 0.00025% aqueous solutions of either methylene blue or neutral red. This staining technique resulted in minimal mortality and marked the translucent fins of the tadpoles for several weeks, allowing accurate identification of sibling groups by visual inspection.

To determine whether tadpoles aggregate with siblings, for each test, 25 tadpoles from one clutch were marked blue, and 25 tadpoles from another clutch were marked red. The 50 tadpoles were then released at randomised positions and allowed to acclimatise for 24 h in an indoor test pool filled to a depth of 3 cm with water. Subsequently, for test periods ranging from 4 to 7 consecutive days, the positions of all tadpoles in the pool and their clutch-identifying colours were recorded twice each day, in the morning and afternoon; thus, each test consisted of 8–14 trials. During each trial a grid of sixteen 0.05-m^2 partitioned sections was lowered into the pool and the positions of all individuals were marked on an acetate sheet fastened over the grid. The partitions limited the movement of the tadpoles during the 90-s period in which data were recorded.

The coordinate positions thus obtained were analysed by comparing the distance of each tadpole to its nearest sibling neighbour with the distance to its nearest non-sibling neighbour. If they aggregate preferentially with siblings, one would expect that tadpoles should be closer to siblings than to non-siblings. This prediction was confirmed in all six experimental tests, using different groups of tadpoles in each test (Table 1). For each test, the mean nearest-neighbour distance between siblings was significantly less than the distance between non-siblings (Fig. 1). Analysis of variance showed this sibling effect to be highly significant ($P < 0.0001$, F-test), whereas variation within experimental tests, among tests and in interactions between effects was not significant (Table 2). The among-tests effect approaches significance, perhaps due to different aggregative tendencies among tadpoles used in different tests.

The results of separate analyses of individual trials further substantiate these findings (Table 1). In the majority of the experimental trials (65%; $n = 62$), the nearest-neighbour distance between siblings was significantly less than that between non-siblings (Table 1). Although discrete aggregations of sibling groups were not always apparent, in 37% of all trials the mean coordinates of the two groups differed significantly (Table 1), indicating that the sibling groups separated out into different areas of the pool. Moreover, the tadpole groups were not simply attracted to different fixed regions of the pool, as their positions changed in sequential trials (Fig. 2). This suggests that the tendency for tadpoles to be closer to siblings than to non-siblings cannot be explained by differential responses of the two groups to possible environmental gradients in the pool.

To control for the possibility that these results were caused by either the marking or testing procedures, we carried out tests in which all 50 tadpoles were from the same clutch. Half of these individuals were stained blue and half red; all other procedures were followed precisely as in the experimental tests. In the two control tests the nearest-neighbour distances between same-coloured tadpoles were not significantly less than those between

Table 1 Group identity and analysis of separate trials within each test

In the experimental tests, egg clutches were obtained from five different pairs of parents (A–E) from four separate ponds (Tompkins County, New York). Pairs A and D were from the same pond; linear distances between the ponds of origin for the other pairs of parents were: A to B, 11 km; A to C, 3.7 km; D to E, 2.6 km. In the control tests, all groups of tadpoles were obtained from the same clutch. Unlike Fig. 1, where whole tests are compared, the individual sequential trials within each test were analysed with respect to (1) whether the distance between siblings was less than that between non-siblings (Wilcoxon signed-ranks test, one-tailed[19]), and (2) whether the mean coordinates of the two sibling groups differed (Mann–Whitney U-test, two-tailed[19]). For example, test 1 consisted of eight trials, in six of which siblings were significantly closer to each other than to non-siblings. In two of the eight trials in test 1 the centres of density (=centroids) of the two groups differed. For this analysis, the centres were considered different if their positions along either the north–south or east–west axis differed significantly.

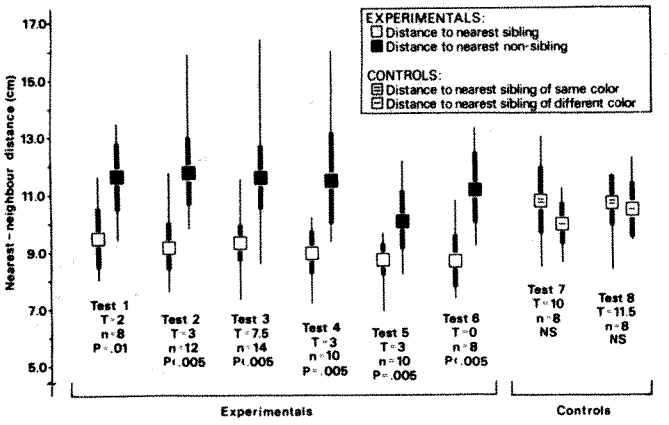

Fig. 1 Mean nearest-neighbour distance between sibling and non-sibling tadpoles (experimentals) and between siblings of the same and different colours (controls). Rectangular bars around means (symbols) represent 95% confidence intervals; vertical lines indicate ranges. Probability levels are given below the data for each test (T, n and P represent the test statistic sample size [number of pairs of trials] and level of significance, respectively). In all six experimental tests, individuals were significantly closer to siblings than to non-siblings ($P \leq 0.01$; Wilcoxon signed-ranks test). In control tests all tadpoles were siblings; same-coloured individuals were not significantly closer to each other than they were to differently coloured tadpoles ($P > 0.05$; Wilcoxon signed-ranks test).

differently coloured tadpoles (Fig. 1). Thus, the possibility that tadpoles in the experimental tests merely positioned themselves near same-coloured individuals can be discounted.

These results provide the first experimental evidence that a lower vertebrate is capable of sibling recognition. The tadpole distributions we found could arise if (1) siblings are directly attracted to one another, or (2) tadpoles avoid individuals they perceive to be non-siblings, perhaps due to aggressive encounters. We do not know what sensory modalities tadpoles use in making this discrimination, nor do we know how genetic and experiential factors effect this response. Siblings develop within a continuous jelly egg mass, and on hatching remain near the remnants of the jelly mass for several days. During these critical early developmental stages, tadpoles might 'learn' to identify siblings. Indeed, a facilitative social environment may be fundamental to the development of most normal sibling interactions[11]. Recognition of siblings might also be modifiable by experience later in life[12]. Clearly, sibling recognition need not be based solely on genetic factors.

Preferential association of tadpoles with siblings in ponds could result in the formation of sibling schools. Within schools, individuals can 'hide' from predators, thus decreasing the likelihood that they will be preyed on[13,14]. Yet to gain this advantage, individuals need not school with siblings. Indeed, the more adaptive strategy for the individual would seem to be to surround itself with non-siblings so that neither it nor its siblings are taken by a predator. However, if tadpoles associate with siblings, as our results suggest, their schooling behaviour may represent more than just 'selfish' cover-seeking. A predator that strikes a schooling individual may learn that tadpoles are distasteful, and thus it would avoid preying on other members of the school. The tadpoles' black body colour might function as a warning signal to further reinforce this 'lesson'. These traits, although not directly beneficial to the prey individual if it is eaten, may be selected for if they provide protection to related individuals in the school which are likely also to carry alleles for these altruistic traits[15]. The alarm pheromone released by injured *Bufo* tadpoles may represent another kin-selected trait, as the signalling individual is always wounded[16,17].

A sibling recognition mechanism could evolve in the following manner. In one individual, a mutation arises for distastefulness. The individual metamorphoses, survives to reproductive age, and produces young, several of which now carry the allele for distastefulness. As tadpoles associate in sibling groups for several days after hatching, because of their relative immobility, the loss of any of these distasteful individuals to a predator will benefit siblings, and thus distastefulness can spread by means of kin selection. Even if the unpalatability of a single larva is not enough to deter a predator, the cumulative noxious effect resulting from eating several larvae might be strong enough to cause future predator aversion to the school[18]. In a similar manner, aposematic coloration could spread. At this stage the benefits of distastefulness are high, but as the tadpoles begin actively swimming, and mixing with non-siblings becomes possible, the benefits become reduced or even negative. Next, a mutation arises for a sibling-association mechanism and is favoured because it prolongs the benefit of distastefulness and

Table 2 Analysis of variance for experimental tests

Source of variation	Degrees of freedom	Sum of squares	F Value	P
Sibling effect	1	77.39	44.06	<0.0001
Time effect (within tests)	7	14.49	1.15	0.36
Test effect (among tests)	5	21.97	2.44	0.06
Sibling × Test	5	5.29	0.59	0.71
Time × Test	35	71.54	1.13	0.36
Sibling × Time	7	6.88	0.55	0.79
Residual error	35	63.07	—	—

Three sources of variation and their interactions were considered. 'Sibling' refers to variation in nearest-neighbour distance dependent on whether or not that neighbour was a sibling. 'Time' refers to variation among sequential trials within single tests; only the first eight trials per test were used. 'Test' refers to variation among the six experimental tests.

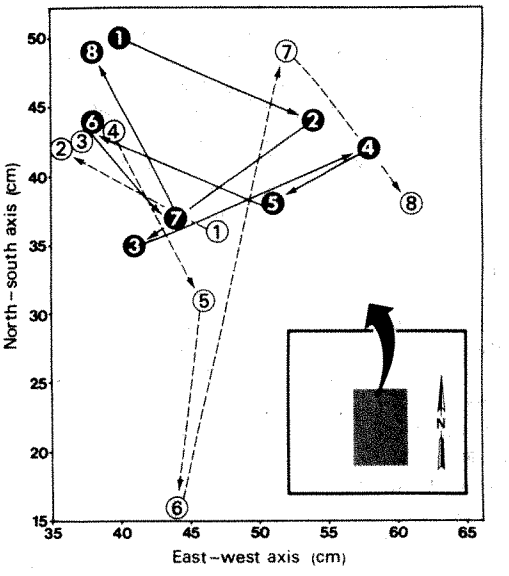

Fig. 2 Movement patterns of two sibling groups of tadpoles in a representative test. Centres of density given here are from test 6; the two sibling groups are group D (solid symbols and lines) and E (open symbols and dashed lines). The numbers inside symbols and the arrows show the sequence of trials in which the test was carried out. The two groups differed significantly in position along either the north–south or east–west axis during trials 1, 2, 3, 4 and 6 ($P < 0.05$; Mann–Whitney U-test, two-tailed). The inset shows the test pool, 88 × 96 cm, and the region of the pool in which the centres of density of the two groups were located (shaded area). A more detailed inspection of the sequential centres of density (trials 1–8) for the two sibling groups shows that each sibling group moved throughout the pool. Tadpoles were not fed during a test, nor were conditions in the pool altered. There was no evidence in this test or in the others that the separate groups preferred particular fixed regions of the pool.

aposematism into later developmental stages. Those individuals which discriminate siblings from non-siblings can preferentially associate with siblings, and thus can effectively direct their altruism towards siblings. This evolutionary scenario does not necessitate an error-free discrimination system; individuals which show any preferential sibling aggregative tendencies should have greater fitness than those which school indiscriminately with siblings and non-siblings. Although work is still in progress to identify the mechanisms by which sibling recognition is accomplished, our results are consistent with the predictions of a kin selection model.

Ca^{2+} is essential cofactor for trypanocidal activity of normal human serum

Jan D'hondt, Nestor Van Meirvenne, Luc Moens & Masatoshi Kondo*

Laboratorium voor Serologie, Institut voor Tropische Geneeskunde, B-2000 Antwerpen and
Departement Celbiologie, Universiteit Antwerpen, B-2610 Wilrijk, Belgium

Normal human serum has been known to exert a cytotoxic effect on *Trypanosoma brucei* subspecies for nearly 80 yr[1]. But in spite of many attempts, no trypanocidal factor was found in human or baboon serum[2–6], until Rifkin demonstrated a high density lipoprotein (HDL) in normal human serum with trypanocidal activity[7]. The conclusion that this was the trypanocidal factor was supported by the report that serum from patients with Tangier disease, characterised by a severe deficiency of HDL, lacked trypanocidal activity[7]. We report here that Ca^{2+} is an essential cofactor for the trypanocidal activity of normal human serum, in which α_2 macroglobulin (α_2) might function as a Ca^{2+}-carrier. We further show that D-glucose, D-fructose and D-mannose can suppress the trypanocidal action of normal human serum, whereas glycerol has the opposite effect.

We used four clones of *T. brucei* subspecies. Clones of the variable antigen types (VATs) AnTat 1 and 8 were derived from a stock of *T. brucei brucei*[8]. A serum sensitive (S) and a serum resistant (R) clone of VAT ETat 2 were derived from a stock of *T. brucei rhodesiense*[8–11]. A large number of cryo-stabilates of each clone was prepared by passage through mice (female OF1 mice) and stored under liquid nitrogen[12]. Trypanosomes were collected from mice 48 h after infection, purified by passage through a DEAE-cellulose column[13], washed and resuspended in PSG (50 mM sodium phosphate buffer, *p*H 8, 36.4 mM NaCl and 83 mM glucose) or BSG (48 mM sodium borate buffer, *p*H 8, 77 mM NaCl and 83 mM glucose). Human serum samples were collected from healthy volunteers, pooled and used immediately for assays or stored at −70 °C until use. *In vitro* assay for the trypanocidal activity of serum was performed by incubating parasites (10^6 cells per ml) at 36 °C in PSG or BSG (unless otherwise noted) in the presence of human serum at the concentration specified in the figure legends. Percentage cell lysis was determined by counting the cell ghosts among at least 500 cells under a phase contrast microscope.

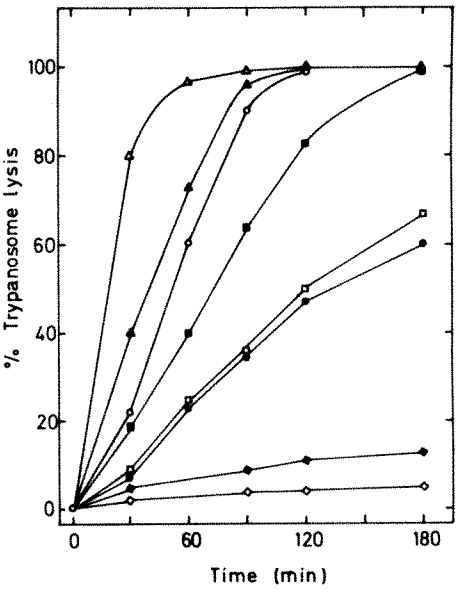

Fig. 1 Effect of dialysis, temperature and Ca^{2+} on trypanocidal activity of normal human serum. Serum was dialysed against PSG or BSG at 4 °C for 24 h with a minimal change of the volume of dialysate. The column-separated *T. b. brucei* AnTat 8 (10^6 cells per 20 μl) was incubated with 980 μl serum at 36 °C for the length indicated in the figure and cell lysis was followed as described in the text. When added, 50 μl of a stock solution of Ca^{2+} or Mg^{2+} was used in 930 μl serum to give a final concentration of 3.2 mM. ○, Undialysed serum; △, plus Ca^{2+}; ●, PSG-dialysed serum; ▲, plus Ca^{2+} or □, plus Mg^{2+}; ■, BSG-dialysed serum; ◇, heat-treated serum (60 °C, 45 min); ◆, plus Ca^{2+}.

Normal human serum, after dialysis against PSG for 24 h, had considerably less trypanocidal activity on *T. b. brucei* AnTat8 than did undialysed control serum, reaching only about 60% cell lysis even after 3 h incubation (Fig. 1). However, the addition of 3.2 mM Ca^{2+} to dialysed serum resulted in a marked restoration of the trypanosidal activity (Fig. 1). The extent of restoration was clearly dependent on the concentration (1.6–12.8 mM) of Ca^{2+} added (Fig. 2). Dialysis against PSG caused a more effective reduction of serum trypanocidal activity than did that against BSG, further implying an involvement of Ca^{2+} in this cytotoxic activity (Fig. 1). Ca^{2+} stimulated the trypanocidal activity, of not only dialysed but also undialysed serum, eliminating an initial lag period at high concentrations of Ca^{2+} (Figs 1 and 2). Another divalent cation, Mg^{2+}, had a negligible effect on the trypanocidal activity of PSG-dialysed normal serum (Fig. 1).

Furthermore, serum deprived of its trypanocidal activity by heat inactivation (45 min at 60 °C) could not be reactivated to a significant extent by the addition of 3.2 mM Ca^{2+} (Fig. 1). Thus the restoration of trypanocidal activity by Ca^{2+} requires the

Table 1 Effect of carbohydrates on trypanocidal activity of normal human serum

Parasite	% Cell lysis in the presence of									
	Control		D-glucose		D-fructose		D-mannose		glycerol	
	PB	HS	PB	HS	PB	HS	PB	HS	PB	HS
T. b. brucei AnTat 1	100	87	1	25	2	27	0	16	0	97
T. b. brucei AnTat 8	100	96	0	35	0	39	0	26	2	100
T. b. rhodesiense ETat 2 S	100	64	0	14	2	19	0	12	0	94
T. b. rhodesiense ETat 2 R	100	2	0	0	0	0	0	0	1	34

Trypanosomes (10^6 cells per ml) were incubated at 36 °C for 2 h in 72 mM (final) phosphate buffer (PB, *p*H 8) or 50% (v/v) normal human serum (HS), containing 145 mM (final) carbohydrates as indicated in the table, except controls where 145 mM PB alone or 50% (v/v) human serum diluted with 154 mM NaCl was used.

presence of an intact trypanocidal factor in the serum, and Ca^{2+} alone cannot exert the cytotoxic effect. In addition, trypanosomes suspended in BSG containing 3.2 mM Ca^{2+} were not affected after 3 h of incubation at 36 °C (not shown).

Human α_2M is a protein ligand for Ca^{2+} (and also for other metal ions) affecting various physiological and immunological reactions[14]. Thus it was conceivable that α_2M in human serum might function at least in part, in addition to free serum Ca^{2+}, as a Ca^{2+}-carrier for a trypanocidal factor. Moreover, a fraction containing trypanocidal factor, reported by Yamaguchi[3] and Rifkin[15], contained both HDL and α_2M. To test this possibility, normal human serum was first treated with rabbit anti-α_2M antiserum, removing all immunologically detectable α_2M but leaving normal amounts of HDL and low density lipoprotein (LDL), and then dialysed against BSG for 24 h. As Fig. 2 shows, the dialysed serum had no trypanocidal activity on *T. b. brucei* AnTat 1, while the addition of 0.8 mM Ca^{2+} restored 60–70% of the activity detected in complete serum. This suggests the active involvement of α_2M in the trypanocidal reaction, possibly as an effective Ca^{2+}-carrier, whose bound Ca^{2+} cannot easily be removed by either dialysis of or the addition of EGTA or EDTA (not shown) to human serum. Rifkin's conclusion[15] that no difference in trypanocidal activity was found between serum absorbed with either rabbit anti-α_2M IgG or normal rabbit IgG can be explained by the fact that no dialysis was performed to eliminate free serum Ca^{2+} after treatment with anti α_2M IgG and sufficient Ca^{2+} (about 2 mM) was present in the *in vitro* assay system. Indeed a maximal trypanocidal activity coincided with the Sepharose 6B column fractions of LDL-free serum, where HDL and α_2M overlapped each other[15].

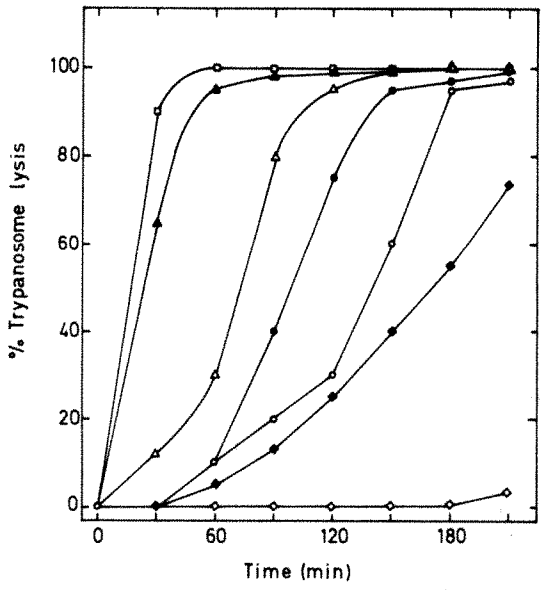

Fig. 2 Effect of Ca^{2+} and α_2M on trypanocidal activity. Serum was treated with rabbit anti-human α_2M antiserum (1.5 mg IgG per ml antiserum, Cappel Laboratories, Cochranville). Both untreated and treated (α_2M-deficient) sera were dialysed against BSG at 4 °C for 48 h. The purified *T. b. brucei* AnTat 1 (10^6 cells per 20 μl) was incubated at 36 °C with 980 μl 50% (v/v) serum or serum containing various concentrations of Ca^{2+} as indicated in the figure. Cell lysis was followed as in Fig. 1. ○, BSG-dialysed untreated serum; ●, plus 1.6 mM Ca^{2+}; △, plus 3.2 mM Ca^{2+}; ▲, plus 6.4 mM Ca^{2+} or □, 12.8 mM Ca^{2+}; ◇, BSG-dialysed treated serum; ◆, plus 0.8 mM Ca^{2+}.

The bloodstream form of *T. brucei* species can utilise D-glucose, D-fructose, D-mannose and glycerol efficiently as carbon and energy sources but depends exclusively on exogeneous carbohydrate because it can not accumulate intracellularly storage polysaccharides[16]. We examined the effect of these carbohydrates on serum trypanocidal activity towards all four *T. brucei* clones, and the results are summarised in Table 1. First, they protected the parasite suspended in 145 mM sodium phosphate buffer (*p*H 8) from lysis during 2 h of incubation at 36 °C. Trypanosomes suspended in buffer without an energy supply were lysed within 10–20 min. Second, the presence of either D-glucose, D-fructose or D-mannose markedly suppressed the trypanocidal activity of normal serum in a concentration dependent manner (not shown). Interestingly, glycerol enhanced trypanocidal activity to some extent, even with the resistant clone of *T. b. rhodesiense* ETat 2 R (Table 1). Thus a simple energy supply to trypanosomes by carbohydrate metabolism is not responsible for altering the capability of trypanocidal factor.

Gruenberg *et al.*[16] have demonstrated, by kinetic analysis of transport systems, that D-glucose and glycerol do not share the same carrier site in the bloodstream form of trypanosomes of *T. brucei*. The first event for trypanolysis by human HDL should be the binding of HDL to the membrane of trypanosome, which may be mediated by a specific surface receptor, as has been shown for serum LDL[18]. Thus it is tempting to suggest that human HDL utilises the specific carbohydrate carrier sites for its interaction with the trypanosome membrane. The carrier site for D-glucose, while involved in its transport, cannot interact efficiently with a trypanocidal factor, whereas the carrier site for glycerol enhances such an interaction. Ca^{2+} requirement for the trypanocidal activity might be mediated, among other possibilities, by its binding to the phospholipid moiety of HDL. The subsequent event involves the alteration of the membrane structure, possibly by removing lipid components as postulated by others[7]. Because subspecies of *T. brucei*, *T.b. rhodesiense* and *T.b. gambiense*, and *T.b. brucei*, cause sleeping sickness in humans and nagana in cattle, respectively, the elucidation of the mechanism by which human HDL causes trypanolysis could contribute to the development of effective prevention and treatment of trypanosomiasis.

A significant aspect of primary hepatic carcinoma in man is the high positive correlation of hepatocellular carcinoma with infection with hepatitis B virus (HBV)[1]. Analysis of the relationship between HBV infection and oncogenesis is difficult because natural infection with HBV is limited to man and experimental infection has been achieved only in chimpanzees and gibbons. Furthermore, because HBV has not been successfully propagated in cell culture, basic study of virus–cell interaction of the aetiological agent of one of the most widespread infections of man has been impossible[2]. Recently, however, a cell line (PLC/PRF/5) derived from a human hepatoma biopsy was described[3] which produces the HBV surface antigen (HBsAg) and so provides a tool for the experimental investigation of HBV *in vitro*. We now report the derivation and characterisation of two additional cell lines from primary liver carcinomas. In contrast to the PLC/PRF/5 cell line, these cell lines retain the capacity to synthesise many human plasma proteins, including both albumin and α-fetoprotein (AFP). One of these lines also produces HBsAg. We also present evidence that HBsAg synthesis and secretion in this cell line are correlated with the growth state of the culture. This finding is in contrast to the continuous HBsAg production found in the PLC/PRF/5 cell line.

The cell lines were established from liver tumour biopsies obtained during extended lobectomies of a 15-yr-old caucasian male from Argentina (1975) and an 8-yr-old black male from the US (1976). Tumour minces were cultured on irradiated mouse cell layers (STO). The cell lines established after these biopsies had been cultured for several months were designated Hep G2 and Hep 3B, respectively, and their morphological characteristics and epithelial cell shape are compatible with those of liver parenchymal cells. Histology of the liver biopsies revealed well differentiated hepatocellular carcinoma with a trabecular pattern. At autopsy of the second patient a portion of the lung, containing suspected metastases, was cultured. The only cells which grew from these tissue fragments were of fibroblastic morphology and are designated Hep 3L.

Supernatants from Hep 3B, Hep G2, PLC/PRF/5, Hep 3L and STO cell lines were tested for the presence of human albumin and AFP by Ouchterlony two-dimensional gel diffusion using commercially obtained antisera. Only the supernatants from the Hep G2 and Hep 3B lines formed precipitin lines which gave a reaction of identity with purified human albumin and human serum and purified human AFP and human placental cord serum, respectively. Human albumin and AFP were analysed quantitatively by radioimmunoassay inhibition testing (Fig. 1). Samples from supernatants of these same cultures were also tested for production of HBsAg, those from Hep 3B were positive whereas supernatants from Hep G2, Hep 3L and STO cultures were repeatedly negative. PLC/PRF/5 supernatants served as a positive control.

Ultrastructural examination of cells from the Hep 3B line was performed using standard electron microscopic techniques. The cells resembled previously described human and experimental liver cell carcinomas[4]. The cells contained prominent cisterns of granular endoplasmic reticulum and a moderate amount of mitochondria; stacks of annulate lamellae and aggregates of glycogen were found in the cytoplasm. No viral particles or cytoplasmic alterations indicative of HBsAg were noted in either apparently healthy or necrotising cells or in the cellular debris.

While monitoring the Hep 3B cultures during the first 1.5 yr of its growth in culture, we observed that the quantity of HBsAg in the supernatants was variable, ranging from undetectable to large amounts. In contrast, supernatants from the PLC/PRF/5 were always positive for HBsAg even within 24 h of subculturing. The same Hep 3B cultures that were variably positive for HBsAg were consistently positive for human albumin. To determine the cause of this variation we monitored the kinetics of HBsAg, AFP and albumin production in a series of replicate

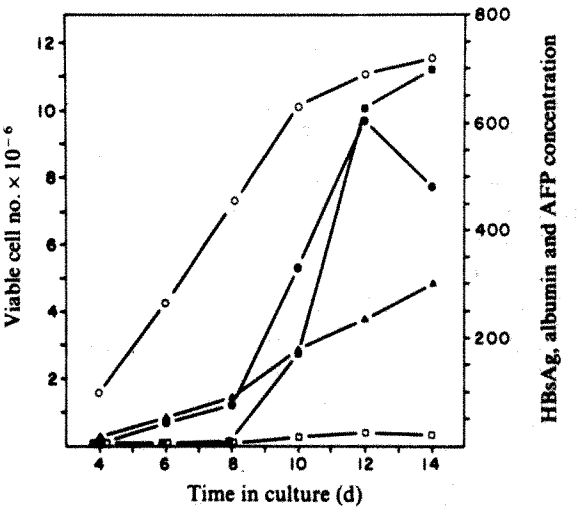

Fig. 1 T75 flasks containing confluent monolayers of Hep 3B cells were tested for HBsAg; those containing >300 ng of HBsAg were used to establish eight replicate cultures. T75 flasks containing monolayers of irradiated feeder layer (STO) cells were seeded with 10^6 viable hepatoma cells in single cell suspension (0.25% trypsin, 1 mM versene, then washed once with medium) and fed with 15 ml Eagle's minimal essential medium (AutoPow, Flow) containing 10% fetal bovine serum (Armor, heated to 56 °C for 0.5 h) and 10 mM glutamine. At days 4, 6, 8, 10, 12, 14, the supernatant fluid was removed, centrifuged and frozen, single cell suspensions prepared as above and viable cells determined by the erythrosin-B dye exclusion method. The remaining cells were washed three times in Dulbecco's modified phosphate-buffered saline, centrifuged, and frozen and thawed four times in 1 ml distilled H_2O. These total cell lysates were also frozen until assayed. Control for each assay included supernatant fluid and/or cell lysates from cultures of Hep G2, Hep 3L, PLC/PRF/5 and STO. HBsAg was quantitated using the AUSRIA II (Abbott) solid phase radioimmunoassay (RIA) kit and comparing positive values to a standard curve with purified HBsAg, determined as part of the same assay (test sensitivity of 0.65 ng ml^{-1}). Albumin and AFP were quantitatively determined in competitive inhibition RIAs by comparing values to standard curves obtained in the same tests with known concentrations of human albumin (Pentex) and AFP (test sensitivity of >20 ng ml^{-1}). Supernatants and cell lysates from STO and Hep 3L were negative for HBsAg, albumin and AFP, Hep G2 samples were negative for HBsAg, and PLC/PRF/5 samples were negative for albumin and AFP. ■, ng HBsAg in supernatant; □, in cell lysate; ▲, μg albumin; ●, μg AFP; ○, viable cell number.

cell cultures by collecting supernatants, determining cell number and preparing cell lysates at various time points. As shown in Fig. 1, HBsAg is not detectable in either supernatants or cell lysates during the first 6 days of subculture, but can be detected by 8 days (11 ng per culture). During this interval, the cell number has increased consistently. HBsAg increased rapidly from day 8 to day 12, whereas the cell number less than doubles during this same time interval. In contrast, albumin is detectable at all time points, increasing with cell number and time in culture. AFP can be found in supernatants throughout the culture growth period, although the increase in the rate of AFP production paralleled that of HBsAg. Cell lysates quantitatively analysed for these proteins gave no evidence for a large internal pool of any of the proteins (Fig. 1, data not shown for albumin and AFP). HBsAg was found in detectable concentrations in cell lysates at the same time as in the supernatants, showing that its rapid increase in the supernatant was not due merely to release of previously synthesised protein.

Culture conditions were examined in an attempt to account for the delay in HBsAg production. To determine whether cell contact is necessary for HBsAg production, the same number of cells were plated throughout a tissue culture dish or restricted to a small portion of the dish by seeding into a plastic ring which was removed 24 h later. No effect of immediate cell contact on the kinetics of HBsAg production was found (Table 1); HBsAg was detected on the same day post-plating and the cultures containing cells in close contact did not produce more HBsAg.

Second, we examined the possibility that a component of fresh cell culture medium hindered HBsAg production or that a cellular product secreted into the medium was necessary for HBsAg production. Feeding of cultures with conditioned medium obtained either from pre-HBsAg positive cultures of Hep 3B (Table 2) or from other human and mouse cell lines (data not shown) did not result in early initiation or increased production of HBsAg, although conditioned medium was capable of supporting cell multiplication (see Table 2 legend for details of culture conditions). When the culture medium is replaced daily with fresh medium, the production of HBsAg is delayed and the quantity reduced (Table 2).

There are several possible mechanisms to explain the delayed appearance of HBsAg in the Hep 3B cell line. The simplest is that the antigen is continuously produced by each cell but that the assay system precludes detection until large amounts of HBsAg have accumulated. This is unlikely because of the sharp rise in the concentration of HBsAg as the cells approach the stationary phase of the growth cycle (Fig. 1). The lowest concentration of HBsAg antigen detectable in this system is approximately 1 ng per culture. As Hep 3B cultures containing 10^7 cells are capable of producing an average of 220 ng of HBsAg within a 24-h period, HBsAg would be detected if it was being continuously synthesised by each cell in the early cultures.

A second possibility is cell cycle control as observed in plasma protein biosynthesis by fetal rat hepatocytes[5]. These studies clearly demonstrated that the synthesis of albumin is independent of the growth state of the cells; the rate of production and release is constant throughout the growth cycle. AFP production by rat hepatocytes, on the other hand, is a function of the position of the cultures in the cell cycle. The curve (Fig. 1) for production of albumin in the human hepatoma-derived line Hep 3B reflects the results observed with rat hepatocytes; albumin is produced and accumulates in the culture supernatant fluid and a plateau is reached when the nutrient state of the culture declines. However, the kinetics of production of AFP and HBsAg by the Hep 3B cells suggests cell cycle control with production occurring when the cells stop dividing and enter the G_0 or resting phase of the cell cycle. This would explain both the appearance of HBsAg in the late log phase of culture growth (Fig. 1) and why cells repeatedly stimulated with fresh medium produce only small quantities of HBsAg. A third possible explanation is that cells in the culture differentiate or mature into terminal cells that are HBsAg producers. Experiments designed to distinguish between the last two possibilities are in progress. Interestingly, in the PLC/PRF/5 cell line, HBsAg is produced throughout the growth cycle (ref. 3 and data not shown).

Speculation on the control of HBsAg synthesis in cell lines must take into consideration the possibility that the viral sequences may be carried as episomal transcriptional units or integrated into the genome of the host. The PLC/PRF/5 genome is host-cell integrated[6] and preliminary evidence indicates that this is also the case for the Hep 3B cell line. As the site of integration may regulate the transcription of the viral information, the controlled production of HBsAg might be indicative of different integration sites in the Hep 3B and PLC/PRF/5 cell lines. Investigation of cell lines derived from human hepatomas, including those negative for HBV expression, should continue to yield insight into the relationship between HBV and human hepatocellular carcinoma.

This work was supported by USPHS grant CA 18470, Research Career Awards AI 0053 (BBK) and CA 00510 (DPA), the National Foundation-March of Dimes 1-301, the American Cancer Society IM 215 and the Merieux Medical Foundation. α-Fetoprotein was obtained from Diagnostic Biochemicals, antisera from Cappel Laboratories, and purified HBsAg was provided by Dr John Gerin.

Hepatitis B surface antigen produced by a human hepatoma cell line

Jacinta Skelly, Jennifer A. Copeland, C. R. Howard & A. J. Zuckerman

Department of Medical Microbiology, and WHO Collaborating Centre for Reference and Research on Viral Hepatitis, London School of Hygiene and Tropical Medicine, London WC1, UK

Infection with hepatitis B virus is associated with the appearance in the serum of a specific antigen, hepatitis B surface antigen (HBsAg), a serologically complex structure present on the coat of the double-shelled 42-nm hepatitis B virus (HBV) particle. HBsAg is also present, often in large excess, in the form of small, spherical 20–25-nm particles in the sera of infected individuals[1]. The serologically distinct core (HBcAg) or nucleocapsid of the 42-nm virus is 27 nm in diameter and contains double-stranded circular DNA with a molecular weight (MW) of $1.6–2.0 \times 10^6$, and an associated DNA polymerase[2]. A third antigen, hepatitis B e antigen (HBeAg), appears to correlate with the number of virus particles[3] and the relative degree of infectivity of surface antigen-positive sera[4], is frequently detected free in the serum and has been shown to be closely associated with the viral core[5]. Failure to propagate hepatitis B virus serially in tissue culture is a major obstacle to precise biochemical characterisation of the antigens and the development of vaccines against this important infection. The use of purified HBsAg 20–25-nm particles prepared from the sera of persistently infected donors for the immunoprophylaxis of hepatitis B is being investigated[6]. Such preparations have been shown to protect susceptible chimpanzees on challenge with HBV[7,8]. There are, however, problems associated with the collection of HBsAg positive sera from persistently infected carriers. The recent establishment of a HBsAg-producing cell line from a human hepatoma[9,10] has provided an alternative source of HBsAg particles with the added advantage that both the production and quality of the antigen may be more precisely controlled. The availability of this cell line also facilitates the study of HBV gene products by biochemical methods applicable to cultured cells, in the absence of contaminating serum proteins. In this study, the 20–25-nm HBsAg particles produced by these cells were characterised and compared with those derived from the sera of persistently infected human carriers.

A study in our laboratory of the rate of HBsAg production showed that it was minimal during logarithmic cell growth, and maximal towards the end of a 7-day maintenance period (J.A.C. *et al.* in preparation). Titres of up to 1.3 $\mu g\ ml^{-1}$ of HBsAg were obtained by incubating confluent cultures in maintenance medium for 7 days. Measurements of HBsAg, HBeAg and DNA polymerase by the most sensitive methods currently available[11] were performed on cell culture fluids, and on pellets derived by ultracentrifugation of the fluids (Table 1). Only HBsAg was detectable. Electron microscopy revealed that the predominant form was the 20–25-nm spherical particle. Pelleted HBsAg was further purified by two cycles of isopycnic banding in CsCl as described previously[12]. The buoyant density determined during this procedure was 1.19 $g\ ml^{-1}$, as found by others[13]. Material banding at this density was radiolabelled with the Bolton and Hunter reagent to a specific activity of 5 $\mu Ci\ \mu g^{-1}$ before further purification[14]. It was then subjected to centrifugation in linear gradients of Urografin[12] (Fig. 1). The majority of the radiolabel was not present in the surface antigen, as only about 10% of it was present in the region of the gradient (fractions 10–14) in which serum surface antigen was found in parallel gradients. Furthermore, when the fractions were tested

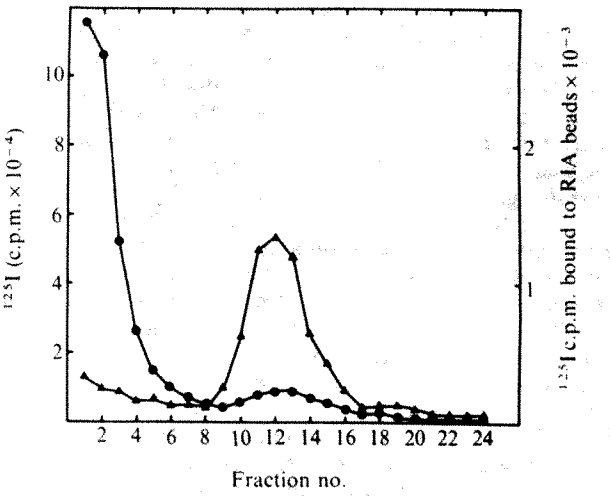

Fig. 1 Centrifugation of radioiodinated, partially purified HBsAg. Antigen was layered on to discontinuous 10–25% gradients of Urografin buffered with 0.01 Tris HCl, *p*H 7.3, and centrifuged at 52,000*g* for 18 h at 4 °C in a Beckman SW 27.1 rotor. Fractions (0.7 ml) were collected and 10-μl aliquots of each were counted in an LKB Ultrogamma counter. Fractions containing radiolabelled HBsAg were detected by direct adsorption to solid phase anti-HBsAg. Aliquots (10 μl) of each fraction were mixed with 200 μl 10% normal human serum in phosphate-buffered saline (PBS) and incubated with antibody-coated radioimmunoassay beads (AUSRIA II, Abbott) for 3 h at 40 °C. The beads were then rinsed with 10 ml of water and counted. ●, Total c.p.m.; ▲, c.p.m. bound to anti-HBsAg. Centrifugation is from left to right.

for radiolabelled HBsAg by adsorption to beads coated with hepatitis B surface antibody (anti-HBs), only fractions 10–14 were positive. These fractions were combined but attempts made to separate the antigen from Urografin by gel filtration[12] or sedimentation were unsuccessful.

In contrast to serum HBsAg, there was evidence of breakdown of the hepatoma antigen particles subjected to these treatments, as shown by failure to recover most of the radioactivity in the void volume or pellets. An alternative to rate-zonal centrifugation was therefore adopted. An affinity adsorbent column was prepared consisting of rabbit anti-HBs IgG adsorbed to protein A-Sepharose. Control experiments showed that HBsAg did not bind to protein A-Sepharose alone, or in the presence of non-immune rabbit serum. Material radiolabelled after the second CsCl step was applied to the column. After extensive washing to remove unbound radiolabel, the IgG and bound antigen were eluted with 3 M sodium thiocyanate (NaSCN). The polyacrylamide gel profiles of the radiolabelled material before affinity chromatography, and of the fraction bound by anti-HBs are shown in Fig. 2*a* and *b*, respectively. The four major polypeptides of the material before affinity chromatography had MWs of 73,000, 64,000, 54,000 and 31,500. In contrast, the MWs of the polypeptides of the affinity-purified antigen were 47,000, 34,000, 28,000 and 23,000. The latter two polypeptides co-migrated with major polypeptides of serum HBsAg run in a parallel gel. The antibody affinity step therefore allowed the recovery of the small fraction of ^{125}I-labelled material with a density of 1.19 ml^{-1} which is HBsAg reactive and uncontaminated by the other constituents of this material.

The results confirm that the HBsAg produced by the PLC/PRF/5 line is very similar in size, morphology and buoyant density to the 20–25-nm spherical particles of circulating serum HBsAg. The purification procedure developed for serum HBsAg[12] was readily adaptable to the purification of hepatoma

0028-0836/79/490617—02$01.00

© 1979 Macmillan Journals Ltd

HBsAg from tissue culture fluids. In spite of the fact that tissue culture supernatant contains considerably less protein than serum, our results showed that the hepatoma HBsAg required extensive purification. After two equilibrium bandings in CsCl, at least 90% of the ^{125}I-labelled protein was not HBsAg. The bulk was material which remained at the top of a Urografin rate-zonal gradient (Fig. 1) and consisted of polypeptides with MWs of 73,000, 64,000, 54,000 and 31,000 (Fig. 2). Hence, it was necessary to devise a suitable final purification step, as recovery of the antigen from the Urografin was low; also the purity and specificity of the final product before polypeptide analysis needed confirmation. Both of these aims were attained by binding of labelled HBsAg to anti-HBs IgG adsorbed to a protein A–Sepharose column. It is concluded that the final product is HBsAg for several reasons: first, it is specifically adsorbed by anti-HBS IgG; second, it contains no trace of the major polypeptides of the contaminating material; and third, it contains two polypeptides of the serum surface antigen[15–17]. Note that the hepatoma surface antigen does not contain the higher MW polypeptides frequently detected in serum HBsAg: in particular there is no polypeptide in the MW range of serum albumin which has been identified as a constituent of highly purified preparations of serum HBsAg. This observation is in agreement with our finding that the hepatoma HBsAg does not bind to Blue Sepharose CL-6B and with the observation of R. Dodd (personal communication) that the hepatoma cells produce little or no albumin. In particular, the finding of polypeptides with MWs of 28,000 and 23,000 in hepatoma HBsAg reinforces the association of these two polypeptides with HBsAg

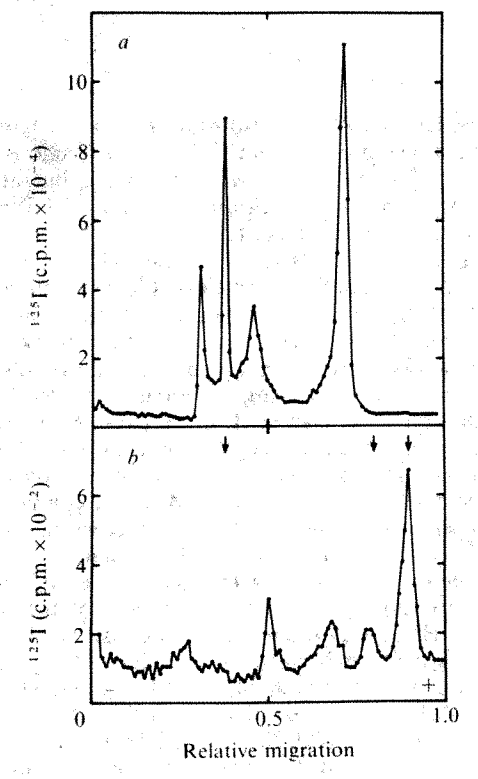

Fig. 2 SDS polyacrylamide gel electrophoresis of material radioiodinated after two isopycnic centrifugations in CsCl (*a*) and of the 3 M NaSCN eluate from the protein A–Sepharose-anti-HBsAg column (*b*). The conditions for disruption and electrophoresis in 10% cylindrical gels were as previously described[12] except that the stock acrylamide solution contained 0.8% w/v methylene bisacrylamide. Radioactivity was determined by counting 1-mm slices. The arrows indicate the positions of p64, p28 and p23 of serum HBsAg run in a parallel gel[12,15].

Table 1 Hepatitis B antigens and DNA polymerase in tissue culture fluid from the PLC/PRF/5 line

	*P/N**	
	Culture fluid	Pellet (75 × concentrate)
HBsAg	581	6,350
HBeAg	1.25	1.22
HBcAg	1.07	0.95
HBcAg after disruption	1.13	1.21
DNA polymerase	0.65	0.91

Measurements of HBsAg, HBcAg, HBeAg and DNA polymerase PLC/PRF/5 culture fluids, and in pellets derived by ultracentrifugation. Fluids were collected from confluent monolayers of cells after 7 days of incubation in maintenance medium (minimal essential medium, containing 1% fetal calf serum.) After a preliminary clarification by low-speed centrifugation, the fluids were centrifuged at 83,000*g* for 18 h in a Beckman SW27 rotor and resuspended in 1/75th the original volume. HBsAg was detected using a commercial radioimmunoassay system (AUSRIA II, Abbott) and HBeAg by a similar procedure using polystyrene beads coated with human IgG positive for anti-HBe. The same reagent was used for the preparation of the radioligand. HBcAg was measured similarly using human sera positive for anti-HBc. For this latter test, a duplicate sample was also treated with 1% NP40 and 0.1% 2-mercaptoethanol to detect the presence of HBcAg within 42-nm virus particles. DNA polymerase was measured as previously described[19].

* c.p.m. in sample/c.p.m. in control.

activity, which was previously demonstrated by Triton X-100 fractionation of serum material[15]. The other polypeptides sometimes found associated with serum HBsAg[17,18] as opposed to hepatoma HBsAg may be tightly bound serum components such as albumin[15], or components of HBsAg produced by normal rather than malignant liver cells. It is not possible to decide between these two alternatives at present.

The simple biochemical composition, and ready availability of HBsAg from the PLC/PRF/5 cell line make this line attractive as a possible source of material for intact particle or subunit vaccines for hepatitis B.

We thank G. F. Mann for advice and tissue culture facilities, Miss R. Smith and Mrs J. Dixon for technical assistance, J. J. Alexander for 73rd passage PLC/PRF/5 line hepatoma cells, and the Wellcome Trust for financial support. The Hepatitis Research Programme at the London School of Hygiene and Tropical Medicine is also supported by the WHO, the Department of Health and Social Security, the MRC and Organon B.V. (Oss, The Netherlands).

Tumour promoter alone induces neoplastic transformation of fibroblasts from humans genetically predisposed to cancer

Levy Kopelovich, Nancy E. Bias & Lawrence Helson

Sloan-Kettering Institute for Cancer Research, 1275 York Avenue, New York, New York 10021

Neoplastic transformation is a multi-phase process apparently caused by carcinogens and subject to the influence of promoters[1–4]. The naturally occurring phorbol esters[4–6] such as 12-O-tetradecanoyl phorbol-13-acetate (TPA) are potent tumour promoting agents. Through the use of phorbol esters a two-stage process of malignant transformation has been demonstrated in the mouse skin model[4–7] and, more recently, in cell culture systems[8–10]. Studies *in vitro* suggest that TPA reversibly inhibits terminal differentiation in most[10], but not all model systems, and that its function is presumably to increase the probability of expression of the malignant phenotype[10]. We have studied the effects of TPA on mutant human fibroblast cell strains derived from individuals with hereditary adenomatosis of the colon and rectum (ACR), an autosomal dominant trait[11]. We have previously demonstrated in these fibroblasts abnormal phenotypic expressions which often appear in transformed cells[12–17]. In these studies, we have assumed that the ACR cell exists in an 'initiated state' due to a dominant mutation and that expression of the malignant state might only require treatment with a promoting agent[18,19]. This simple experimental protocol provided a novel system for the study of cancer promotion *in vitro*[20,21]. We have now demonstrated, for the first time, the growth *in vivo* of human mutant cells exposed to TPA alone.

Subepidermoid biopsy specimens were taken from flat skin of normal appearance from ACR individuals and normal volunteers at the Memorial Sloan-Kettering Cancer Center[12]. Skin fibroblasts (SF) that grew out around the explant as a monolayer were isolated and carried in culture. The cells were grown in Earle's minimum essential medium and Earle's balanced salt solution (GIBCO) supplemented with 2 mM glutamine, 1% non-essential amino acids, penicillin (100 U ml^{-1}), streptomycin (100 $\mu g\ ml^{-1}$) and 10 mM HEPES buffer, *p*H 7.25 (EMEM) in the presence of 15% fetal calf serum (FCS). The cell strains were used between the 5th and 12th passage and were routinely checked for bacteria and mycoplasma.

The protocol for obtaining the cells used in the nude mouse inoculation experiments is shown in Fig. 1. Cells were plated in 75-cm^2 flasks at an initial density of $4 \times 10\ cm^{-2}$, and TPA (100 ng ml^{-1}) in 0.01% dimethyl sulphoxide (DMSO) was added at day 1 post-plating. Near-confluent cultures of these TPA-treated cells were continuously passaged in culture at a subculture density of $4–6 \times 10^3$ cell cm^{-2} (about 10–14 d per passage). On each passage, SF from a parallel subculture were plated in agar in the presence of 100 ng ml^{-1} of TPA and examined for colonies 4 weeks later. SF from another culture were injected bilaterally into the anterior chamber of the eye of athymic mice at a concentration of about 1×10^6 cells per 0.02 ml phosphate-buffered saline (PBS) per eye.

Table 1 describes the following cell cultures injected into the athymic mice: a DMSO-treated ACR cell culture (ME), a TPA-treated ACR cell culture (ME) which did not grow in agar during seven consecutive passages in liquid culture (Fig. 1), and a TPA-treated ACR cell culture (PF) which grew in agar (Ag I) and has been isolated from agar-growing clones on passages 2 and 4 for further studies (Fig. 1)[20,21]. As shown in Table 1, the two TPA-treated cell cultures gave rise to tumours in athymic mice, but only the PF cells were descendants of TPA-induced

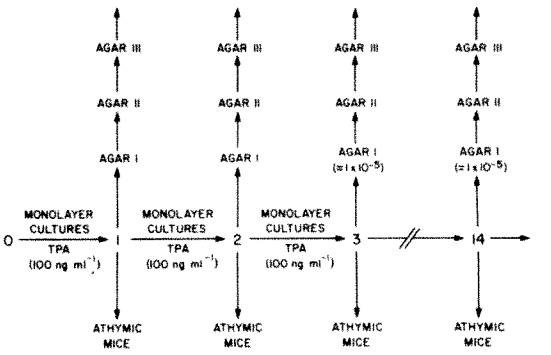

Fig. 1 The protocol for TPA-treated cells. Agar plates were prepared essentially as described elsewhere[30]. Nutrient agar (Difco), 1.84% (w/v), was melted in boiling water and equilibrated at 45 °C. It was then mixed with 2 × EMEM–30% FCS containing 200 ng ml^{-1} TPA/0.02% DMSO 1:1 (v/v) at 45 °C, and 4 ml were plated on to each of 3–5 60-mm dishes as an underlayer and allowed to firm for 15 min at room temperature. Another portion of this solution was mixed with a cell suspension of 5×10^4 cells ml^{-1} in 1 × EMEM 1:1 (v/v) containing 100 ng ml^{-1} of TPA in 0.01% of DMSO or DMSO alone. This preparation (4 ml), representing 1×10^5 cells per dish, was plated over the base layer and allowed to firm for 1 h at room temperature in a chamber irrigated with 5% CO_2. Agar colonies were scored microscopically after about 4 weeks of incubation at 37 °C in a humidified 5% CO_2 incubator. Inoculation of the nude mice (CD-1) was carried out with cells that were trypsinised, counted and washed twice with PBS to give a final cell concentration of 1×10^6 per 0.02 ml of PBS. A volume of 0.02 ml was injected under a magnifying glass bilaterally into the anterior chamber of the eye. The mice were checked every week for the appearance of tumours. These usually became apparent at 2 weeks post-injection and were removed 1–2 weeks later. Each number represents a consecutive passage.

anchorage-independent colonies (Fig. 1; Ag I). To date, we have not obtained tumours with DMSO-treated ACR cells, DMSO-treated normal cells or TPA-treated normal cells (Table 1).

At about 4 weeks post-inoculation, the optic nerve was severed and the intact eye was removed and placed in 10% formaldehyde for histological examination. A cross-section through the eye (perpendicular to the optic nerve–cornea axis) shows the occurrence of an apparently well differentiated tumour, characterised by uniformly appearing, highly basophilic, fibroblast-like cells (Fig. 2). Tumours were obtained in all mice injected with the TPA-treated ACR cells, although not always bilaterally (Table 1).

We have previously demonstrated an unusual biphasic dose–response relationship for cultured human SF to TPA[20,21], perhaps suggesting that TPA affects at least two distinct processes of cell proliferation—one which is inhibitory to cell growth, but can be saturated at relatively low concentrations, and another at the higher concentration range, which stimulates cell proliferation. Whether these results suggest the existence of at least two cell populations each of which displays a distinct type of receptor for TPA, or a single cell population with at least two types of receptor for TPA remains to be established. Consequently, in the present report we chose to study the malignant transformation of ACR cells at a high TPA concentration (100 ng ml^{-1}).

The chronic application of TPA also effects a loss of anchorage sensitivity of ACR cell cultures[20,21]. Cells selected for anchorage independence might presumably respond primarily to the growth-stimulating ability of TPA and this fraction may then conceivably be enriched by serial transfers in agar[21]. However, we found that growth in agar due to TPA occurs at a low frequency, cannot be serially sustained beyond two passages in agar (Fig. 1, Ag II) and is variable for a given human cell strain during consecutive passages in liquid culture[20,21]. For example, the human strain PF has given rise to anchorage-independent colonies at passages 2 and 4, but not at passages 1, 3, 5 and 6.

Table 1 Effect of TPA on the tumorigenicity of ACR cells

Cell strains and treatment	Dose–response pattern to TPA*	Growth in agar	Tumours formed‖
DMSO/HC†	NA	–	0/4
TPA/HC†	Bimodal	–	0/3
DMSO/ME‡	NA	–	0/3
TPA/ME‡	Bimodal	–	4/4 (4)‖
TPA/PF§	Bimodal	+	3/3 (2)

TPA was always applied at a concentration of 100 ng ml^{-1} in 0.01% DMSO and was changed twice weekly. Controls received 0.01% of DMSO alone. TPA-treated subconfluent cultures were split at a density of $4–6 \times 10^3$ cells cm^{-2}. Colonies retrieved from agar were expanded in liquid cultures in the presence of TPA until enough cells had become available for inoculation in the nude mice. NA, not applicable.

* See refs 20, 21, and text.

† Represent SF from normal individuals. The dose–response curve of normal SF to TPA is apparently bimodal, but these cells are about 50–100-fold more sensitive to TPA than are ACR cells[20]. The latter may be due to a significant reduction in receptor sites for TPA and/or a change in the affinity of binding of TPA to its receptors in ACR cells.

‡ Represent SF from individuals with the Gardner variant of familial polyposis coli (ACR).

§ Represent SF from a clinically asymptomatic individual who is one of the F_1 progeny of an ACR pedigree and who is positive by our tests[12–22] for this trait. To date, no differences have been observed in our studies between the general case of ACR and the Gardner variant.

‖ Figures in parentheses indicate the number of mice with tumours occurring in both eyes.

This same cell strain did not grow in agar in three subsequent experiments. The human strain ME, which in this study did not grow in agar at all during seven consecutive passages, has been previously shown to grow in agar at a similar frequency to PF. However, both cell strains formed tumours all the time. The results suggest a high degree of heterogeneity in the human cells which is more apparent during selection of the TPA-induced anchorage-independent phenotype than during the process of tumour formation in athymic mice. In other words, the probability of a TPA-induced tumour is considerably higher than that of a TPA-induced anchorage independence in our system (Table 1). The results may further suggest that a loss of anchorage dependence is not necessarily a prerequisite of tumour growth and that these two processes may be modulated in parallel by separate control mechanisms[22]. In this regard, a TPA-induced permanent loss of anchorage dependence has been demonstrated with stable 'initiated' mouse epidermal cells in culture[23].

TPA has been shown to enhance the stable transformation of murine, and more recently, of human foreskin fibroblasts previously exposed to a carcinogen[8,9,24,25]. Thus, our results may indicate that the ACR mutation is a complete one for malignancy, representing an initiated state[22], and that the chronic application of TPA, in support of the two-stage 'Berenblum-hypotheses' (ref. 4) can precipitate the final oncogenic event. Alternatively, this cell mass growing *in vivo* may represent an intermediary state, similar perhaps to the TPA-induced stable papillomas in the mouse skin model[4–7] or to the clinical appearance of polyps in the colon. The latter would suggest that an additional mutation(s) is necessary for the malignant transformation of ACR cells with certain promoters acting during all phases of oncogenesis to increase the probability of expression of the malignant phenotype.

The possibility that chromosomal restructuring is associated with promotion of malignancy by TPA[26–28] in our cell system remains to be established. In this respect, an elegant analysis of lymphoma development that proposes diversity of initiation followed by convergent cytogenetic evolution has recently been enunciated[29]. The way in which the presence of TPA in ACR cells might effect a transition from the initiated state to the malignant state is now being investigated.

We thank Dr Robert A. Good for suggesting the eye as an immune-privileged site in the nude mouse system, Dr I. Bernard Weinstein for helpful discussions, Mrs C. Helson for help in the inoculation of the nude mice, and Ms P. Monaghan and Ms R. Vuolo for technical assistance. This work was supported in part by grant CA 19259 from the National Large Bowel Cancer Project, and NCI grant CA 08748 and contract N01 CP 43366.

Note added in proof: We have recently demonstrated that TPA-treated ACR cells which grew in athymic mice showed about 33% increase in cell aneuploidy (L.K. and R. Moon, unpublished). These chromosomal aberrations, if stable, may conceivably be consistent with a somatic mutation(s).

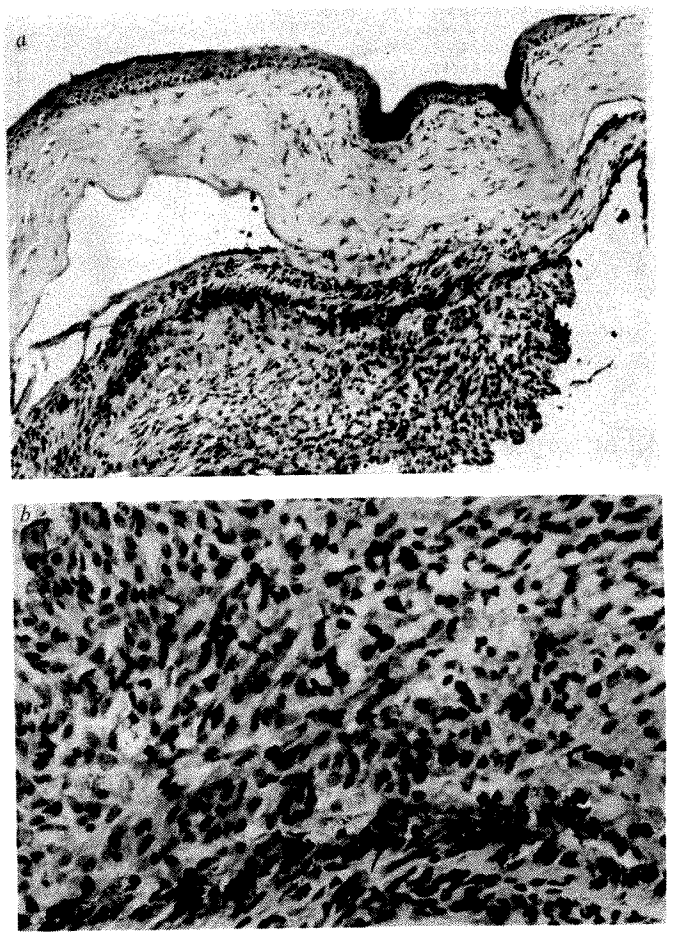

Fig. 2 A histological section of a tumour through the anterior chamber of the eye. *a*, Eyes were severed at the optic nerve and placed *in toto* in a 10% formaldehyde solution for 48 h. Cross-sections were made perpendicular to the cornea–optic nerve axis. ×90. *b*, As in *a*, magnified ×225. The pigmented particles (lower part) arose from the iris during sectioning in the periphery of the eye.

Galactosyltransferase and membrane glycoprotein abnormality in human platelets from Tn-syndrome donors

J. P. Cartron

A. T. Nurden

U150 INSERM, Hôpital Lariboisière, 2, rue Ambroise Paré, 75475 Paris Cedex 10, France

Early studies on the analysis of membranes isolated from the erythrocytes of Tn-patients by SDS-polyacrylamide gel electrophoresis (SDS-PAGE) revealed a severe reduction in the staining capacity of glycophorin with the periodate-Schiff (PAS) reaction[1,2]. A low sialic acid and galactose (Gal) content of the polyagglutinable red cells was confirmed[3] while it was reported[2,4] that the abnormal red cells of Tn-patients contained little or no UDPGal: GalNAc-β-3-D-galactosyltransferase (T-transferase) activity. The glycoprotein (GP) abnormality in Tn-erythrocytes appeared to be due to incomplete synthesis of the alkali-labile oligosaccharide chains of glycophorin[2]. We now report studies on the membrane GP composition and the T-transferase activity of platelets isolated from three Tn-syndrome patients whose red cell membranes contain GP abnormalities which are typical of those found in this rare clinical condition[1,2].

There is increasing evidence that the unmodified presence of certain membrane glycoproteins is vital for the normal haemostatic functioning of blood platelets[5]. The disaccharide β-D-galactosyl (1–3)*N*-acetyl-D-galactosamine, which is the determinant of the T-antigen, has been demonstrated on the surface of human red cells[6,7] and platelets[8]. In normal human erythrocytes the T-antigen is substituted with sialic acid. The pathological exposure of the T-antigen or α-glycosidically linked *N*-acetyl-D-galactosamine (GalNAc) residues may lead to the polyagglutination of the red cells, as antibodies against the exposed antigens are present in most adult sera[9]. The polyagglutination resulting from the exposure of α-GalNAc residues forms the basis of the Tn-syndrome[10]. The frequent association between the exposure of Tn-receptors on red cell membranes and a low platelet count[10] suggested that similar modifications might also be present in the platelets of Tn-donors.

Platelets from each patient were washed and analysed by SDS-PAGE. The GP profiles of platelets isolated from patient Ba are compared with those of normal human platelets in Fig. 1. Major changes were observed in the GP pattern of the Tn platelets. The individual PAS-staining platelet glycoproteins contain different amounts of inter- and/or intramolecular disulphide bonds and exhibit characteristic changes in migration on SDS-PAGE that are dependent on the state of reduction of the disulphides[11]. Analysis of the non-reduced GP profiles clearly showed that the GP Ib/Is band was primarily affected in the Tn platelets, with its PAS-staining capacity being markedly

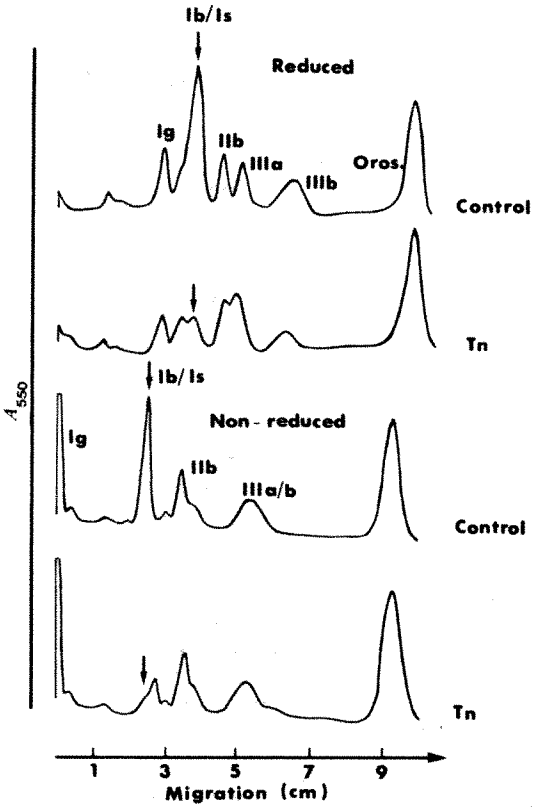

Fig. 1 A comparison of the glycoprotein profiles of normal human and Tn platelets. Washed platelets were isolated as previously described[17] and resuspended at 2×10^9 ml^{-1} in 0.01 M Tris-HCl, *p*H 7.0, containing 0.15 M NaCl, 3 mM EDTA and 5 mM *N*-ethyl maleimide. The platelets were solubilised by heating at 100 °C for 5 min following the addition of one fifth volume 12% SDS. SDS-PAGE was performed either following reduction of disulphide bonds at 37 °C for 1 h, in the presence of 5% v/v 2-mercaptoethanol (reduced samples, upper profiles) or in the absence of disulphide bond reduction (non-reduced samples, lower profiles). Electrophoresis was performed according to the procedure of Laemmli[20] using 10.5×0.5 cm polyacrylamide separating gels containing 6% acrylamide 0.2% bis (reduced samples) or 7% acrylamide 0.2% bis (non-reduced samples). Protein (400 μg) was applied to each gel together with 5 μg orosomucoid. Glycoproteins were located by the PAS reaction[17] and the gels scanned densitometrically at 550 nm. The orosomucoid acted as an internal standard for the PAS reaction. Glycoprotein profiles of platelets isolated from Tn donor Ba are illustrated. Arrows indicate the position of the Ib/Is peak.

decreased. The residual GP Ib/Is also migrated slightly faster on SDS-PAGE, suggesting that it was of a lower than normal molecular weight. The criteria used for the identification of the PAS-bands labelled in Fig. 1 are detailed elsewhere[12,13]. GP Ib, IIb, IIIa and IIIb are membrane glycoproteins. Following SDS-PAGE of unfractionated normal platelets the PAS-staining intensity of the GP Ib band is increased relative to that of the other membrane glycoproteins[12,13]. GP Is refers to the fraction of this band that has been shown to be released from the surface of washed platelets during homogenisation; it has also been termed glycocalicin[14]. GP Ib and Is may represent two fractions of a structurally similar glycoprotein[14]. GP Ig refers to an intracellular, granule-localised, glycoprotein[12].

The SDS-PAGE glycoprotein profile of the platelets of a second Tn-syndrome patient, Az, is shown in Fig. 2. In this profile the residual GP Ib/Is peak was slightly greater than was observed with the platelets of the donor Ba. We[2] have provided evidence for the presence of a dual population of erythrocytes in the blood of most Tn individuals, that is to say a subpopulation of erythrocytes with normal GP profiles and normal T-transferase activity coexisted with the pathological red cells. To

investigate the possible presence of a dual population of platelets in Tn donors and that the abnormal GP profiles of Tn platelets was accompanied by the exposure of GalNAc residues on the platelet surface, aliquots of platelet rich plasma from patients Az and Du were separated on affinity columns of Sepharose 6MB-*Helix pomatia* lectin. This lectin specifically recognises terminal GalNAc groupings[15]. Typical SDS-PAGE glycoprotein profiles of the platelet subpopulations which either bound (HP + ve) or were not retained by the column (HP − ve) are shown in Fig. 2. The HP − ve subpopulation gave a normal GP profile, while analysis of the HP + ve platelets revealed little PAS-staining in the GP Ib/Is position.

Initial studies demonstrated the presence of T-transferase activity in lysates prepared from the platelets of normal donors (Table 1), the level of activity being independent of the ABO blood group. T-transferase activity was strongly reduced in lysates prepared from washed platelets isolated from each of the three Tn-donors studied. When the total population of platelets isolated from donor Du (with 30% of the normal level of platelet T-transferase activity) were separated into the HP − ve and HP + ve subpopulations, practically all of the T-transferase activity was located in the HP − ve platelets. As illustrated in Fig. 2 for the donor Az the HP − ve platelets had a normal GP composition, whereas little PAS-staining was observed in the GP Ib/Is position for the HP + ve platelets. Incubation of Tn-platelet lysates for 18 h at 37 °C with purified T-hapten resulted in no detectable Gal release and no evidence of an increased galactosidase activity.

Glycoprotein abnormalities have previously been reported in two congenital platelet disorders, Glanzmann's thrombasthenia and the Bernard-Soulier syndrome[5,12]. Little or no PAS-staining is observed in the GP IIb and IIIa positions following SDS-PAGE of thrombasthenic platelets, and recent results suggest severe molecular deficiencies of these membrane glycoproteins[12,16]. In the Bernard-Soulier syndrome, little or no PAS-staining is observed in the GP Ib/Is position[12,17]. As shown in Fig. 2, the HP + ve Tn platelets presented a GP profile similar to that observed with Bernard-Soulier platelets. In view of this, T-transferase activity was measured in lysates obtained from platelets isolated from a thrombasthenic and a Bernard-Soulier patient, respectively (Table 1). T-transferase activity was within the normal range in both lysates suggesting that the mechanism by which the GP abnormalities occur in thrombasthenic and Bernard-Soulier platelets is different to that found in the Tn-syndrome.

Table 1 UDPGal: GalNAc-β-3-D-galactosyltransferase (T-transferase) activity in human platelets

Donors		Blood group	Platelet count ($10^9\,l^{-1}$)	T-transferase activity* (pmol $mg^{-1}\,h^{-1}$)
Normal ($n = 7$)		A, B or O	200–400†	178 ± 28‡
Thrombasthenia BI.C		O	200	175
Bernard-Soulier Viv.		A	70	154
	Ba	O	70	13
	Az	O	120	46
Tn	Du whole platelets	O	53	58
	Du HP − ve platelets			125
	Du HP + ve platelets			17

* Measurement of the T-transferase activity was performed on platelet lysates obtained by incubating 10^9 washed platelets in 100 µl 10 mM tris-maleate buffer *p*H 7.4, containing 1% v/v Triton X-100. The assay was performed in a total volume of 100 µl containing 80 µg platelet protein, 10 µmol sodium cacodylate buffer *p*H 6.5, 1.5 µmol $MnCl_2$, 0.5 µmol *p*-nitrophenyl-2-acetamido-2-deoxy-α-D-galactopyranoside (GalNAc-α-Nph) and 0.68 nmol UDPGal ^{14}C-galactose (specific activity 280 mCi $mmol^{-1}$). After incubation for 3 h at 37 °C, the reaction product ^{14}C-Gal-β(1–3)GalNAc-α-Nph (T-hapten) was isolated by paper chromatography and quantitated by liquid scintillation counting as previously described[2].

† Normal range.

‡ Mean ± standard deviation.

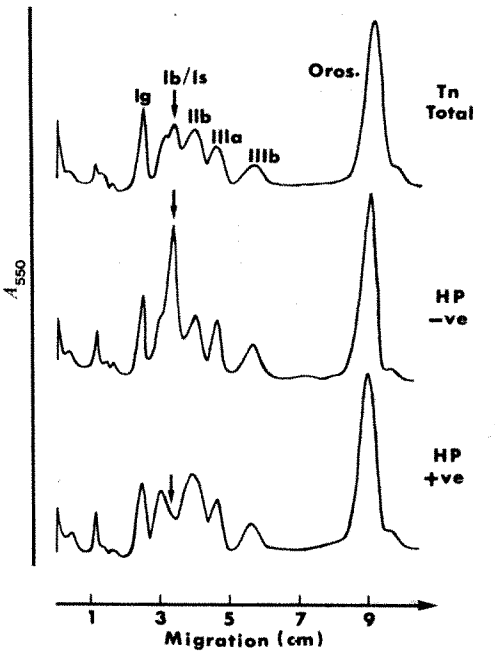

Fig. 2 Glycoprotein profiles of Tn platelet subpopulations. Platelet-rich plasma was applied to a 15 × 0.5 cm column of Sepharose 6MB-*Helix pomatia* lectin (Pharmacia) equilibrated with 0.01 M sodium phosphate, *p*H 7.2, containing 0.15 M NaCl, 50 µg ml^{-1} apyrase (Sigma) and 0.5% bovine serum albumin. Platelets not retained on the column (HP − ve) were eluted directly with the above buffer, the platelets retained on the column (HP + ve) with buffer containing 0.1 M GalNAc. The isolated subpopulations and a sample of the total platelet population were washed, solubilised with SDS, incubated with 2-mercaptoethanol and their glycoprotein composition analysed by SDS-PAGE as described for Fig. 1. Glycoprotein profiles of platelets isolated from Tn donor Az are illustrated. Arrows indicate the position of the Ib/Is peak.

The low T-transferase activity in Tn-platelets strongly suggests that the GP abnormality, as in Tn erythrocytes, arises from an incomplete synthesis of the oligosaccharide chains of the glycoprotein(s) constituting the GP Ib/Is band. This conclusion is supported by the recent detection of the T-antigen in isolated human platelet membranes[8] and the observation that binding sites for *Arachis hypogaea* lectin (which has a specificity for the T-antigen) are specifically located in the GP I position following SDS-PAGE[18]. To our knowledge, our results represent the first direct demonstration of a membrane GP abnormality common to both platelets and erythrocytes. They also point to possible similarities within the structure of platelet GP Ib/Is and glycophorin, and support the hypothesis that a somatic defect occurring in the primitive stem cells of haematopoietic tissue may be the underlying cause of the platelet and red cell abnormalities in the Tn-syndrome[19]. In common with previous reports[10] each of the Tn-donors studied possessed a circulating platelet count lower than the normal level (Table 1). Whether there is any association between the platelet GP defect and the low platelet count remains to be proved. However, the specificity of the glycoprotein defect suggests that Tn platelets provide an additional model for the investigation of the possible roles of the membrane glycoproteins in platelet function.

We thank Mlle Dominique Dupuis and Mlle Cécile Rahuel for technical assistance and Drs D. Lee, M. O'Sullivan, H. H. Gunson and P. Sylvestre for supplying the blood samples from the Tn-syndrome donors. This work was supported by a grant from INSERM CRL 78.5.128.1 and from DGRST MB/P256.

Insulin binds to brain blood vessels *in vivo*

Mark van Houten & Barry I. Posner

Department of Medicine, McGill University, Montreal, Quebec, Canada H3A 2B2

The brain has generally been considered an insulin-independent organ, because insulin does not apparently exert a direct effect on brain glucose consumption[1]. Recently, however, insulin receptors have been detected throughout the central nervous system (CNS) of several species[2,3]. Since important insights into the functional significance of brain insulin receptors might be provided by identification of the cell type(s) possessing these receptors, we have attempted to localise them morphologically using light and electron microscope autoradiography. We report here results indicating that blood vessels throughout the CNS of the rat bind plasma insulin rapidly and with considerable specificity.

^{125}I-labelled porcine insulin (21.9×10^7 c.p.m., specific activity 134 μCi μg^{-1}) in the absence or co-injected presence of graduated amounts of unlabelled insulin, or structurally dissimilar polypeptides, ovine prolactin or bovine adrenocorticotropic hormone (ACTH), was injected intracardially into anaesthetised male rats, as previously described[4]. Five minutes after injection brains were perfused through the heart with Ringer's lactate, to wash out blood and unbound radioactivity, followed immediately by Bouin's fixative solution. Coronal 4-μm thick sections of paraffin-embedded slabs of fixed brain were stained with modified Harris' haematoxylin and eosin, and processed autoradiographically for light microscope visualisation of bound radioactivity[5].

Light microscope autoradiography showed that, in addition to prominent reactions over the circumventricular organs, which have been described elsewhere[4], ^{125}I-insulin was bound to blood vessels throughout the CNS (Fig. 1). Autoradiographic reactions occurred over brain blood vessels of all dimensions, except the large muscular blood vessesls located along the perimeter of the brain.

Although the intensity of individual blood vessel reactions did not superficially appear to correlate with the size or shape of the vessel profile, there were obvious differences in the overall regional intensity of vessel reactions among different brain regions. To achieve some quantitative appreciation of these differences, the intensity of blood vessel reactions from several regions was estimated with reference to a uniform population of vessel profiles. Thus, for grain quantitation we considered only small round nucleated vascular profiles within a narrow range of luminal diameters (13–17 μm). These microvessels were selected to provide an index of the overall intensity of blood vessel reactions for the purpose of inter-regional comparison, as they represented units of luminal surface area which were numerous and morphologically convenient to identify under the light microscope with the aid of an ocular micrometer. The total number of silver grains over 100 of these 'standardised' microvessel profiles, scored without bias, was tallied for each of several regions of brain from rats in each injection group. The average of these totals was used to estimate variations in ^{125}I-insulin binding to brain blood vessels.

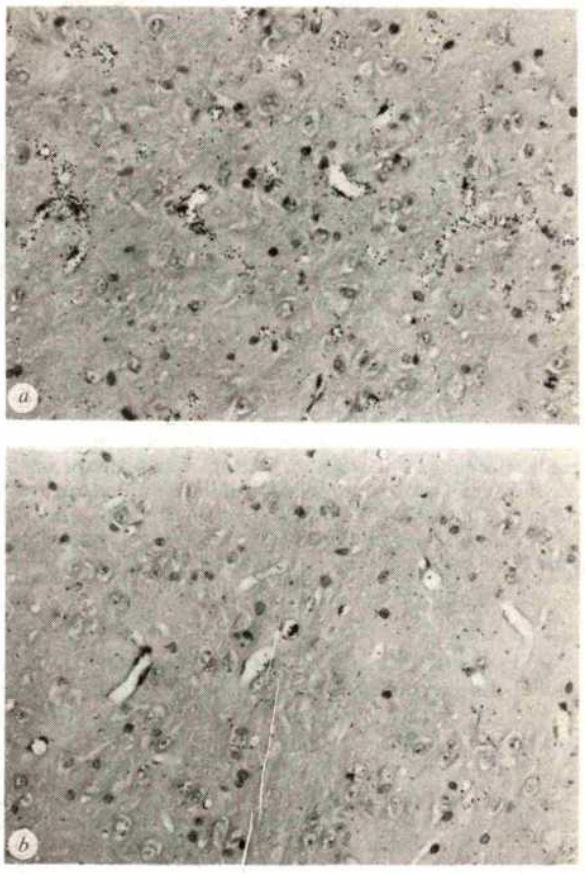

Fig. 1 The intensity of autoradiographic reactions over all neocortical blood vessels from rats injected with ^{125}I-insulin (*a*) is drastically reduced in rats co-injected with a 500-fold excess of unlabelled insulin (*b*). ×212; 2 month exposure.

In rats injected with ^{125}I-insulin alone there was marked regional variation in insulin binding to brain microvessels (Fig. 2). The most intense autoradiographic reactions occurred in neocortex, hippocampus and hypothalamus. Less binding occurred with microvessels in cerebellum and pons, and the least binding with microvessels from white matter structures, such as corpus callosum and optic chiasm. Fortuitous inclusion of the trigeminal ganglia in our autoradiographic series revealed that microvessels in this structure of the peripheral nervous system also bind plasma insulin (Fig. 2).

Quantitation of microvessel reactions was also useful in estimating the effect of unlabelled insulin and structurally unrelated polypeptides on ^{125}I-insulin binding to cerebral blood vessels. Co-injection of a 500-fold excess of unlabelled insulin reduced ^{125}I-insulin binding to brain microvessels in all regions to about the same level (Figs 1, 2). The average reduction in autoradiographic reaction was 60–70% over grey matter microvessels, but only 40–50% over white matter microvessels, because these blood vessels bound less ^{125}I-insulin when this was injected alone.

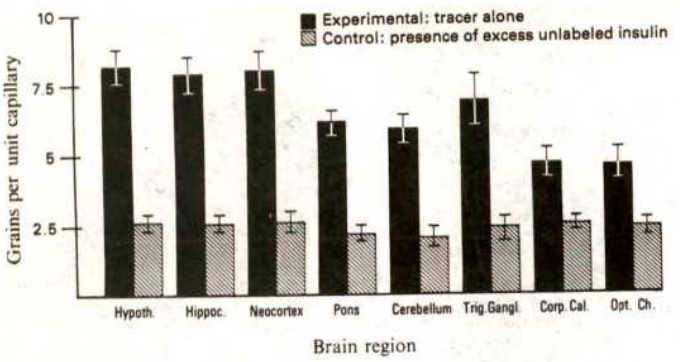

Fig. 2 Regional variations in the specific binding of ^{125}I-insulin to brain microvessels *in vivo*. The average number of silver grains (±s.e.m.) over 100 standardised microvessels (termed 'unit capillaries') is compared between experimental and control rats for several different regions of brain. Quantitation was accomplished with the aid of an 11 × 11 mm ocular micrometer disk and a Zeiss Photoscope at a magnification of ×1600. Estimates of background fog over non-radioactive brains showed 0.35 ± 0.15 grains per unit capillary.

Co-injection of ^{125}I-insulin with intermediate amounts of unlabelled insulin produced a stepwise reduction in the average reaction over neocortical microvessels, but co-injection of prolactin or ACTH had no effect (Fig. 3). These observations indicate that neocortical microvessels bind plasma insulin with a considerable degree of specificity. The specificity of the binding of insulin to cerebral blood vessels is confirmed by our recent autoradiographic studies showing that blood-borne ^{125}I-human growth hormone[6] and ^{125}I-angiotensin II (ref. 7) do not bind to cerebral vasculature.

The possible cellular location of ^{125}I-insulin binding sites in association with neocortical blood vessels was tentatively identified by means of electron microscope autoradiography of the neocortex of rats injected intracardially with ^{125}I-insulin, and killed 5 min later by perfusion–fixation as before, except that a solution of mixed aldehydes served as fixing agent. Most silver grains examined in thin section autoradiographs[8] of neocortex were situated as shown in Fig. 4 in relation to endothelium. As extensive quantitative methods[9,10] are required to determine the precise location of the bound radiolabel, our electron microscope observations must be taken as preliminary. The present data do, however, suggest that the endothelial cell may be the site of the binding interaction (M.v.H. and B.I.P., in preparation).

The results of this study demonstrate the presence of insulin-specific binding sites in association with rat brain blood vessels.

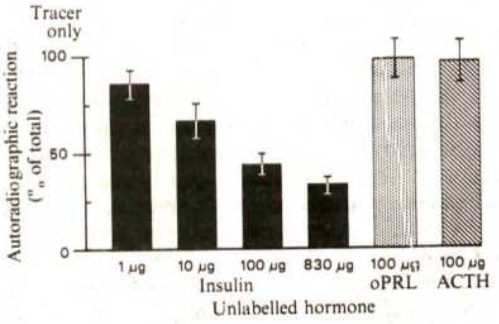

Fig. 3 Effect of unlabelled insulin and other polypeptide hormones on ^{125}I-insulin binding to neocortical microvessels. The average number of silver grains over 100 microvessels from rats injected with ^{125}I-insulin along with graduated amounts of unlabelled insulin, ovine prolactin (oPRL) or bovine ACTH is expressed as a percentage of the average number of silver grains per microvessel obtained with injection of ^{125}I-insulin alone (% of total).

All regions of brain examined showed vascular binding of insulin, although there was considerable regional variation in insulin binding capacity: the greatest insulin binding occurring with grey matter microvessels of the forebrain, and the least binding with white matter structures. It is unlikely that regional variations in insulin binding to blood vessels can be attributed to possible intrinsic differences in regional cerebral blood flow, and thus to differences in vascular accessibility to blood-borne insulin, because regional variations in autoradiographic reactions ceased when ^{125}I-insulin was co-injected with unlabelled insulin (Fig. 2). On the other hand, it is more likely that regional differences in blood vessel-associated reactions reflect regional differences in the capacity of cerebral blood vessels to bind specifically plasma insulin. This being the case, brain blood vessel binding sites for insulin may account in part for the widespread distribution of insulin receptors in the rat CNS[3].

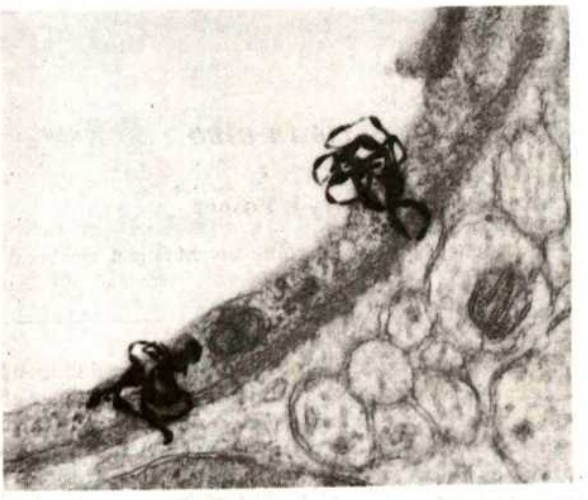

Fig. 4 Representative micrograph showing the typical location of silver grains in electron microscope autoradiographs of neocortex from a rat injected systemically with ^{125}I-insulin. The visual impression gained from examining many such grains strongly suggest that the endothelial cell is directly binding insulin. ×33,000; 4 month exposure.

Indeed, the rank order of brain regions according to microvessel binding of ^{125}I-insulin *in vivo* using autoradiographic methods (Fig. 2) is strikingly similar to the rank order of regions according to receptor content, as determined by classical direct binding studies[3].

Are brain blood vessels targets for the direct action of insulin? The specificity of insulin binding to brain blood vessels argues for these vessels having the recognition capacity concomitant with an ability to respond to plasma insulin. However, it is generally assumed that insulin has no direct effect of any kind on brain activity because it does not alter the rates of glucose transport across the blood–brain barrier[1]. The intriguing studies of Arieff *et al.*[11], on the other hand, suggest that insulin may directly stimulate potassium uptake by the brain *in vivo*, and that a direct action of insulin on brain electrolyte balance exerted at the level of the endothelial cell may contribute to the onset of insulin-induced seizures. Although by no means supporting this concept, the present localisation of insulin binding sites to cerebral blood vessels does raise the possibility that insulin may exert a generalised effect on brain activity by a direct action on aspects of blood–brain barrier function perhaps unrelated to glucose uptake.

In view of the possible relevance of the present observations to the general vascular complications of diabetes, it is important to determine whether insulin-receptor blood vessels exist outside the CNS. Bar *et al.*[12] recently identified genuine insulin receptors on endothelium isolated from human umbilical vein.

Autoradiographic studies similar to the ones presented here should be carried out to determine whether vascular beds in other tissues possess insulin binding sites.

Localisation of phencyclidine-induced changes in brain energy metabolism

Richard C. Meibach, Stanley D. Glick, Russel Cox & Saul Maayani

Department of Pharmacology, Mount Sinai School of Medicine, New York, New York 10029

The abuse of phencyclidine [1(1-phencyclohexyl)piperidine, PCP], commonly referred to as angel dust or hog, is rapidly reaching epidemic proportions. PCP users often appear violent and increases in PCP-implicated homicides and suicides have been reported[1]. In animal studies PCP has been demonstrated in brain up to 48 h after administration, long after blood levels become undetectable[2]. However, there is little further information on the distribution of PCP within the central nervous system with regard to the possible sites of action. Recently, Sokoloff and associates[3,4] described a new technique which can be used to visualise possible sites of drug action. The technique is based on the premise that neuronal activity is closely related to energy metabolism. Therefore, by directly monitoring 2-deoxy-D-glucose consumption before and after a pharmacological stimulus, we can obtain autoradiographic evidence of changes in neuronal activity in discrete areas of brain as a response to that stimulus. Using this procedure, we now report that PCP causes dramatic changes in glucose metabolism in very specific regions of the rat brain.

Female Sprague–Dawley rats (250 g) were used in all experiments. In pilot studies the peak dose/response of PCP as tested behaviourally in a rotometer was 5 mg per kg 40 min after intraperitoneal administration (S.D.G. *et al.*, in preparation). Thus, 40 min after PCP injection, animals were injected with 25 μCi of ^{14}C-2-deoxy-D-glucose (specific activity 53 mCi mmol^{-1}, NEN), administered through a cannula implanted in the right jugular vein 24 h before injection[5]. The conscious, freely moving animals were killed 30 min later by decapitation and processed for autoradiography[3].

The autoradiograms presented a striking effect of PCP on local cerebral glucose metabolism. Both increases and decreases were markedly apparent as determined by comparing the densities of the X-ray autoradiograms. The major sites of increased metabolism were components of the limbic lobe. Specifically, glucose consumption was increased in the molecular layer of the regio superior of the hippocampus. Both dorsal and ventral levels of the hippocampus were affected, although the greatest increases seemed to occur at posterior levels. This line of increased activity continued dorsally through the subicular cortex and into the retrosplenial cortex (posterior cingulate gyrus) (Fig. 1*d*). The anterior cingulate gyrus (Fig. 1*e*) and anteroventral nucleus of the thalamus demonstrated similar increases. Smaller increases in glucose utilisation were seen in a few non-limbic structures such as substantia nigra. An unusual finding was that the inferior colliculus, which normally has the highest energy demands of all brain areas[3], showed a marked loss of metabolic activity (Fig. 1*f*).

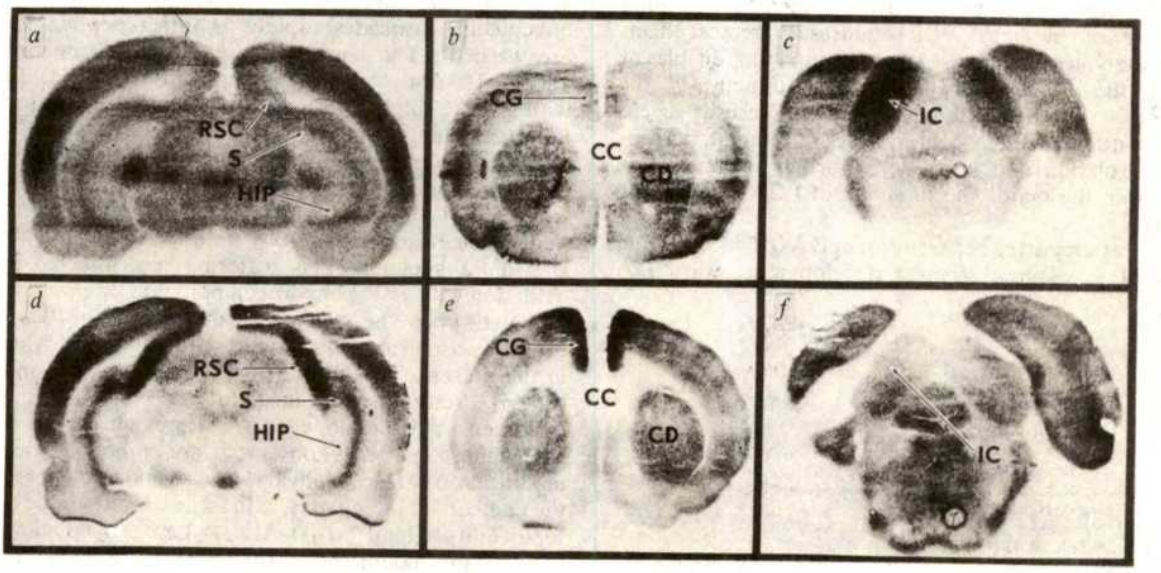

Fig. 1 Autoradiograms taken from three different levels in untreated (*a–c*) and PCP-treated (*d–f*) animals. Note line of increased intensity (glucose metabolism) in hippocampus (HIP), subiculum (S) and retrosplenial (posterior cingulate) cortex (RSC) which continues rostrally (*e*) into anterior cingulate cortex (CG). At the level of the midbrain (*c*, *f*) there is a dramatic decrease in intensity in the inferior colliculus (IC). CC, corpus callosum; CD, caudoputamen.

0028–0836/79/490625—02$01.00

© 1979 Macmillan Journals Ltd

Nature Vol. 282 6 December 1979

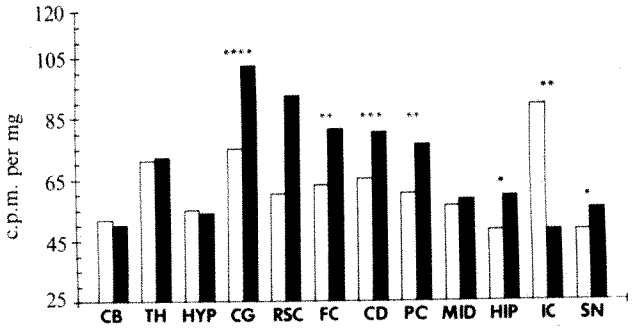

Fig. 2 A comparison of ^{3}H-deoxyglucose uptake in untreated ($n = 7$) animals (open bars) and in animals receiving 5 mg per kg PCP ($n = 7$) 40 min before injection of ^{3}H-deoxyglucose (solid bars). CB, cerebellum; TH, thalamus; HYP, hypothalamus; CG, anterior cingulate gyrus; FC, frontal cortex; CD, caudeputamen; PC, posterior cortex; MID, midbrain; IC, inferior colliculus; SN, substrata nigra. MID includes IC and SN, but was further dissected into IC and SN in three additional animals. The RSC was removed from only two animals. *Significantly different from normal in paired t-test, $P<0.05$; $^{**}P<0.02$; $^{***}P<0.01$; $^{****}P<0.005$.

In an attempt to quantify the changes in energy metabolism without using a densitometer, we repeated our experiments substituting a tritium-labelled isotope for the ^{14}C (50-μl injections with specific activity 40 Ci mmol^{-1}). After death, the brains were removed, weighed, dissected into 12 regions and homogenised in 1 ml sodium phosphate buffer, pH 7.4. 100 μl aliquots (in quadruplicate) were removed, dissolved in 10 ml of NEN scintillation cocktail and 1 ml distilled water, and counted in a Beckman LS9000 scintillation counter (30% efficiency). The results of these experiments completely supported the autoradiographic data (Fig. 2); that is, the cingulate gyrus reflected the largest increase in glucose consumption (37%) whereas the inferior colliculus had the largest decrease (54%). In addition, increases in glucose consumption which were not apparent on visual inspection were found in both the frontal cortex and caudoputamen.

The present study clearly demonstrates a marked effect of PCP on the limbic system. Papez originally proposed an emotional circuit linking the cingulate gyrus, hippocampus and anterior thalamus[6]. Later studies have included the subicular cortex in these connections[7,8]. PCP produces its greatest effects on energy metabolism in all these structures and thus enables us to visualise the functional Papez circuit directly in the autoradiograms. The fact that in humans PCP causes severe emotional disorders including disturbances of thought, perception, mood, isolation and hostility[1] is further evidence that within the brain the major site of action of PCP is within the limbic system.

Role of disulphide and sulphydryl groups in clustering of enkephalin receptors in neuroblastoma cells

Eli Hazum, Kwen-Jen Chang & Pedro Cuatrecasas

Department of Molecular Biology, The Wellcome Research Laboratories, Research Triangle Park, North Carolina 27709

Image intensified fluorescence microscopy has been very useful in visualising the patterns and mobility of receptors for epidermal growth factor (EGF), insulin and α_2-macroglobulin in intact cells[1,2]. Recently, we have synthesised a bioactive derivative of enkephalin[3], Tyr-D-Ala-Gly-Phe-Leu-Lys-rhodamine, and used it for the microscopic visualisation and localisation of opiate (enkephalin) receptors in neuroblastoma cells[4]. In contrast to the case of polypeptide hormones[1,2], where fluorescently labelled receptors are initially distributed uniformly and quickly form patches which are subsequently internalised[1,2], the enkephalin-labelled receptor patches in neuroblastoma cells appear only slowly and are not internalised[4]. Sulphydryl groups are involved in the binding of opiates to brain membranes and may affect differentially the binding of agonists and antagonists[5,6]. Also, sulphydryl and disulphide groups are involved in the binding sites of adrenergic, cholinergic and muscarinic receptors[7–11]. These observations prompted us to examine the effects of disulphide and sulphydryl reagents on the clustering of opiate (enkephalin) receptors in N4TG1 neuroblastoma cells. We report here that in these cells there are reactive sulphydryl and disulphide groups which are essential for cluster formation (but not binding), and that a sulphydryl–disulphide exchange reaction may be involved in this process. In addition, the sulphydryl reagents seem to dissociate the two steps of binding and cluster formation, and thus provide a tool for studying the pharmacological importance of receptor clustering.

When N4TG1 neuroblastoma cells are incubated with 10^{-8} M of a rhodamine-labelled enkephalin derivative (30–40 min at 25 °C), many patch-type areas of bright fluorescence, spreading over the cell surface, are detected (Fig. 1*a*). These patches do not internalise[4] with longer periods of incubation at 25 °C or 37 °C. Furthermore, most of the fluorescent patches disappear and more than 95% of the cell-bound radioactively labelled enkephalin dissociates rapidly as intact peptide if the cells are washed[4]. The clusters are not seen in the presence of 10^{-6} M [D-Ala^2, D-Leu^5] enkephalin (Fig. 1*b*). Incubation with specific sulphydryl reagents (10^{-3} M iodoacetate, 10^{-4} M iodoacetamide, 10^{-5} M *N*-ethylmaleimide or 10^{-3} M 5,5′-dithiobis(2-nitrobenzoic acid)) in conditions identical to those used for binding assays (Table 1) result in the uniform distribution of the fluorescently labelled receptors (Fig. 1*c*); fluorescence can be displaced (inhibited) by 10^{-6} M [D-Ala^2, D-Leu^5] enkephalin. This pattern is not affected by further oxidation with 10^{-4} M hydrogen peroxide. Identical results are obtained when the cells are pretreated with 10^{-5} M dithiothreitol, washed and treated with sulphydryl-modifying reagent, in the presence or absence of subsequent oxidation (data not shown). Pretreatment or incubation in the presence of 10^{-4} M hydrogen peroxide alone does not prevent cluster formation. The diffuse patterns observed are probably due to the modification of free sulphydryl groups and not to a reduction in the number of binding sites, as in these conditions the cells retain their ability to bind ^{125}I-[D-Ala^2, D-Leu^5] enkephalin (Table 1).

When the rhodamine–enkephalin derivative is added to the cells in the presence of 10^{-5} M dithiothreitol, no patches are seen and the fluorescence is distributed evenly over the cell surface (Fig. 1*d*), even after prolonged (2 h) incubation at 25 °C. This diffuse pattern (10^{-5} M dithiothreitol, 40 min) is quickly

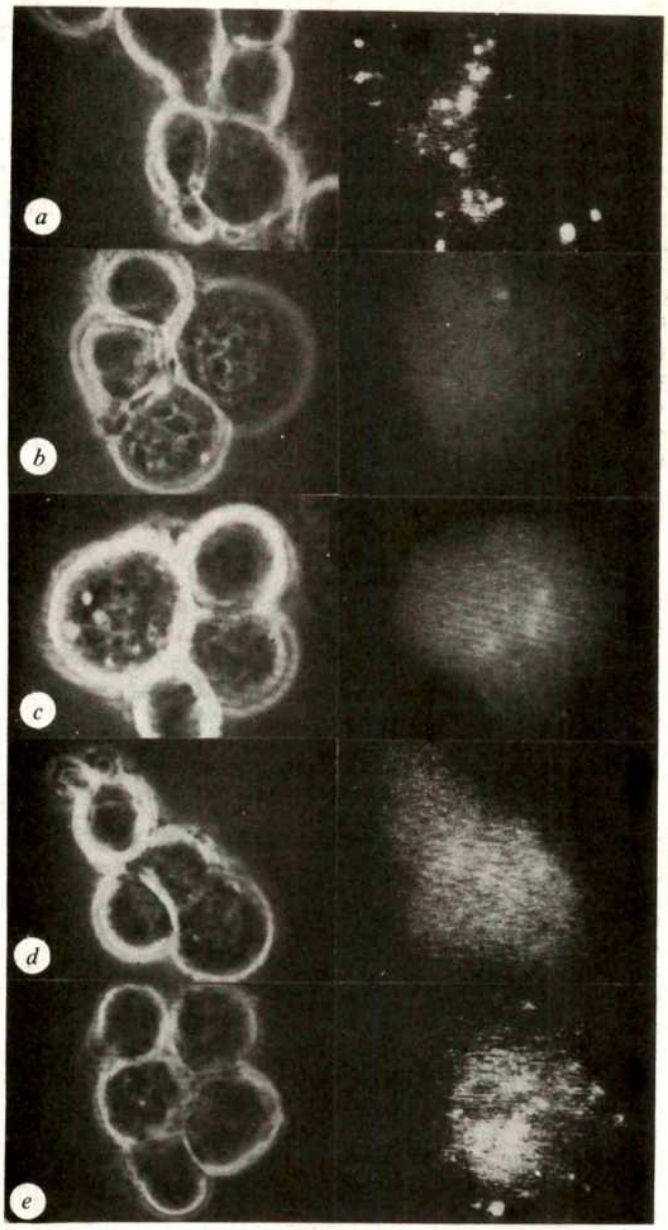

Fig. 1 Fluorescent visualisation of rhodamine–enkephalin binding to N4TG1 cells. On the left, phase micrographs ×865 on the right, fluorescence micrographs of the same field. *a*, The cells were incubated for 40 min at 25 °C with 10^{-8} M rhodamine derivative; *b*, incubation as in *a* but in the presence of 10^{-6} M [D-Ala^2, D-Leu^5] enkephalin; *c*, incubation (identical conditions as for binding assays in Table 1) with 10^{-3} M iodoacetate; *d*, incubation with 10^{-5} M dithiothreitol; *e*, pretreatment with 10^{-5} M dithiothreitol (30 min) followed by addition (for 10 min) of 10^{-4} M H_2O_2. Identical results to that shown in *c* were obtained with 10^{-4} M iodoacetamide, 10^{-5} M *N*-ethylmaleimide and 10^{-3} M 5,5′-dithiobis(2-nitrobenzoic acid). The fluorescence was recorded on videotape using a silicon intensified target television camera[4], and photographs were taken from the video monitor. The cells were not fixed for these studies.

(10–15 min) modified to one of clustering by oxidation with 10^{-4} M hydrogen peroxide (after 10 min, Fig. 1*e*; after 15 min it is similar to that seen in Fig. 1*a*). Clusters reappear spontaneously but slowly (about 75 min) when the cells are pretreated for 20 min with 10^{-5} M dithiothreitol, washed and incubated at 25 °C in the presence of the fluorescent peptide. However, the size, brightness and number of clusters are reduced (data not shown) compared with the control (Fig. 1*a*) or with hydrogen peroxide-induced oxidation (Fig. 1*d*).

The clusters, once formed, cannot be dispersed by the subsequent addition of 10^{-3} M iodoacetate, 10^{-4} M iodoacetamide or 10^{-3} M dithiothreitol, suggesting that the sulphydryl and disulphide groups are protected when the hormone is bound to the receptor and clusters are formed. The clusters can be dispersed by the addition of 100 mM sodium, which also markedly reduces the binding of the peptide, or by the simultaneous addition of 10^{-3} M dithiothreitol and 100 mM sodium. These results are consistent with previous studies with brain membrane preparations[5,6] which suggest that sulphydryl groups are associated with the opiate receptor and that binding of the hormone reduces their reactivity with sulphydryl-alkylating reagents.

Table 1 Effect of sulphydryl, disulphide and miscellaneous reagents on ^{125}I-[D-Ala^2, D-Leu^5] enkephalin binding and clustering in N4TG1 cells

Reagent	^{125}I-[D-Ala^2, D-Leu^5]-enkephalin specific binding (% control)	Hormone–receptor complex pattern
Iodoacetate		
0.1 mM	100	Few clusters
1 mM	89	Uniform distribution
10 mM	83	Uniform distribution
Iodoacetamide		
0.01 mM	95	Few clusters

0.5 mM	100	Clusters
1 mM	98	Clusters
Methylamine hydrochloride		
1 mM	81	Clusters
10 mM	76	Small reduction in the number of clusters
30 mM	52	Few clusters

N4TG1 neuroblastoma cells were grown in Dulbecco's modified Eagle's medium with 10% fetal bovine serum. At confluence, the cells were removed from the flask by incubation with 1 mM EDTA for 5 min at 37 °C. The detached cells were washed three times with 25 mM Tris-HCl, *p*H 7.7, containing 0.25 M sucrose, 2 mM $MgCl_2$ and 5 mM glucose, and finally suspended in the same buffer. Fluorescence microscopy was done as described in Fig. 1 legend. Binding assays: the radioactive enkephalin (0.5 nM, specific activity 2 Ci μmol^{-1}) was incubated with different concentrations of the reagent at 25 °C for 60 min in a final volume of 0.25 ml containing N4TG1 cells (4×10^6 cells ml^{-1}). When iodoacetate and iodoacetamide were tested the cells were pretreated with the reagent for 15 min at 25 °C, washed by centrifugation and the binding measured by filtration under vacuum through Whatman GF/C filters as described previously[14–16]. Specific binding represents the bound radioactivity which can be competed for by 10^{-6} M unlabelled [D-Ala^2, D-Leu^5] enkephalin; each value is the mean of duplicate incubations which varied by less than 5%. All reagents were dissolved immediately before use.

To investigate further the mechanisms involved in clustering we examined the effects of sodium azide (1 and 10 mM) and dinitrophenol (0.5 and 1 mM), as shown in Table 1. The results suggest that the formation of clusters, in these conditions, is independent of the generation of metabolic energy. The effects of methylamine on clustering were also examined as this reagent has been found to inhibit the clustering of α_2-macroglobulin and EGF on the fibroblast cell surface[12]. It was suggested[12] that certain amines may act by increasing the intracellular *p*H, thus possibly interfering with protein–protein interactions necessary for clustering, or alternatively by inhibiting a calcium-requiring transglutaminase enzyme which may be involved in cluster formation. No inhibition of clustering is seen with 1 mM methylamine whereas with 10 mM there is a small reduction in the number of clusters. At 30 mM methylamine only a few clusters are observed but the binding is substantially reduced (52%). Moreover, in contrast to the observations with α_2-macroglobulin and EGF, in which clusters are not formed in the absence of extracellular calcium, the clusters in neuroblastoma cells are formed in the absence or presence of calcium or EDTA[4].

It is interesting that the nature of the binding and surface distribution of the neuromodulator, enkephalin, is quite different from that of polypeptide hormones with respect to internalisation[1,2,4,13] and the effects of sodium and calcium[4]. Our data strongly suggest that both sulphydryl and disulphide groups are specifically involved in the molecular processes involved in the aggregation of ligand–receptor complexes in neuroblastoma cells. Whether the clusters are formed or stabilised by simple sulphydryl–disulphide interchange reactions, or whether these functional groups are involved in some other capacity such as transglutaminase[12], remains to be established. However, prevention of cluster formation without affecting receptor binding may provide a tool for studying the roles of receptor occupancy and subsequent clustering in such biological effects as opiate tolerance and addiction.

We thank Joanna T. Rogers and Lydia J. Hernaez for assistance in growing the neuroblastoma cells.

Relationship between crystallin mRNA expression in retina cells and their capacity to re-differentiate into lens cells

R. M. Clayton*, I. Thomson† & D. I. de Pomerai‡

Differentiating vertebrate embryo tissues pass through a stage when they have the potential for several pathways of differentiation, some of them revealed only by experimental manoeuvres. As differentiation proceeds, the potential for alternative pathways becomes progressively restricted and is eventually lost. We have investigated the molecular basis for this phenomenon, using the chick embryo retina, which has a potential for differentiation into lens cells. This potential requires special conditions for its manifestation; it declines during development and is finally lost before hatching. Lens protein (crystallin) mRNA is expressed in early embryo retina: its levels decline in parallel with the decline in lens-forming potential. There is also evidence of an ontogenic change in post-transcriptional regulation. Such a relationship between heterologous mRNA and heterologous differentiation potential may be of general application.

In the vertebrate eye the neural retina (NR) and the pigmented epithelium (PE) of the retina are of different developmental origin to the lens, but embryonic cells from both tissues are able to redirect their differentiation in cell culture into lens fibre cells, with characteristic ultrastructure, and containing the characteristic lens proteins, the crystallins. This phenomenon has been termed transdifferentiation: it has been found in all vertebrates so far tested[1–3]. In the chick, which has been the most intensively studied example, the expression of the capacity for transdifferentiation is regulable by cell culture conditions[1,3–5] and depends on the age of the embryo, transdifferentiation being more frequent and more rapid from retina of early as compared to later embryos, while the relative balance of the crystallins synthesised is also affected[6–8]. The three classes of crystallins in birds are the α-, β-, and σ-crystallins. Lentoids (structures composed of lens fibre cells) have the highest proportions of σ-crystallins when derived from retinas of earlier embryonic stages (Table 1).

We have found that crystallin mRNAs are expressed in 8-day embryo neural retina (NR) at levels of about 0.025% and in 8-day embryo retinal pigmented epithelium (PE) at levels of about 0.04% of those found in 1-day-old lens, but embryo muscle and headless embryos contain no detectable crystallin mRNAs as measured by hybridisation to crystallin-specific cDNA[9]. During the process of transdifferentiation into lens from 8-day embryo NR or PE, the levels of crystallin mRNA rise, and in terminally transdifferentiated NR cultures, reach between 14% and 17% of the levels found in 1-day-old lens. Terminally transdifferentiated PE cultures reach 1.25% of the level in day old lens[1,10,11].

Since the rate and frequency of transdifferentiation from $3\frac{1}{2}$-day embryo NR is 2–3 times higher than from 8-day embryo NR, we tested the hypothesis that the levels of crystallin mRNA expressed in the earlier stages will be higher than in the later stages.

The hybridisation data (Fig. 1) show that $3\frac{1}{2}$-day embryo eye cups (future NR and PE) express crystallin mRNAs at about 10 times the level found in 8-day embryo NR, while none can be detected in the retina of 1-day-old chicks, by which stage transdifferentiation into lens is no longer possible (ref. 8 and Table 1). Paradoxically, although low levels of crystallin protein are detectable in 8-day embryo NR[12], we have not detected crystallins in $3\frac{1}{2}$-day eye cups, suggesting possible ontogenic changes in the regulation or the translatability of the mRNA.

Evidence pointing to post-transcriptional sequestration for some β-crystallin mRNA has been reported for day-old chick lens[13]. It remains to be tested whether sequestration of crystallin

¶ Haemagglutination inhibition assay. Limits of detection for antisera used: α, 0.01%; β, 0.01%; σ 0.005%.

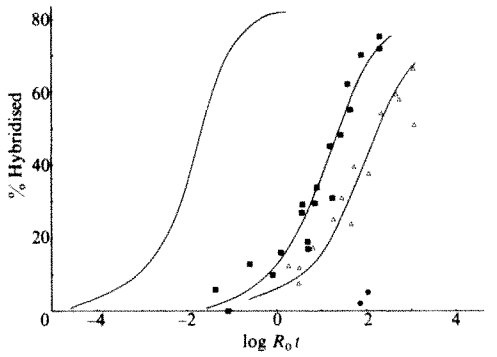

Fig. 1 Lenses from 500 $3\frac{1}{2}$-day-old chick embryos were removed, checked for their integrity and discarded to eliminate all possibility of contamination of eye cups by fragments of lens. The eye cups were then excised and stored in liquid nitrogen. Cytoplasmic mRNA and soluble protein were prepared from two separate such aliquots[10–12]. Neural retina from 100 8-day embryos and retina from 50 day-old hatched chicks was similarly processed. The protein fraction from each sample was analysed by haemagglutination inhibition assay using antisera to crystallins[12]. Total cytoplasmic RNA was prepared from each of these tissues by first homogenising in 0.35M sucrose, 10 mM Tris *p*H 7.5, 50 mM KCl, 1.5 mM $MgCl_2$, followed by centrifugation at 10,000*g* for 10 min at 4 °C. RNA was extracted by addition of an equal volume of phenol/chloroform (1 : 1 by volume), 0.05% 8-hydroxyquinoline, and collected by ethanol precipitation. Poly(A)-containing RNA was fractionated by two cycles of oligo(dT)-cellulose chromatography, and collected by ethanol precipitation as before. Complementary DNA (cDNA) was synthesised from 1-day-old lens[9]. mRNA at 100 μg ml^{-1} was added to a 100 μl incubation mix containing 10 μg ml^{-1} oligo(dT)$_{12-18}$, 75 μg ml^{-1} actinomycin D, 375 μg ml^{-1} bovine serum albumin, 50 mM Tris-HCl *p*H 8.2, 5 mM Mg acetate, 50 mM NaCl, 2 mM dithiothreitol, dATP, dGTP, and dTTP (each at 400 μM) and 45 μM ^{3}H-dCTP (20 Ci mmol^{-1}). Abundant cDNA (complementary only to the crystallin mRNA) was prepared by two cycles of hybridisation to lens mRNA to a R_0t value allowing only hybridisation of the most abundant sequences[9]. Appropriate volumes of mRNA and cDNA solutions in sterile distilled water were mixed, lyophilised and redissolved in 0.5 M NaCl, 25 mM HEPES *p*H 6.8, 0.5 mM EDTA, and 50% (v/v) deionised formamide. Aliquots were heated to 60 °C for 5 min, and allowed to hybridise at 43 °C for various times. The proportion of cDNA in the hybrid was determined by resistance to treatment with S_1 nuclease[9]. ■, $3\frac{1}{2}$-day embryo eye cup mRNA; ●, 1-day-old chick retina mRNA; △, 8-day embryo neural retina mRNA. For comparison, the solid line to the left shows values for 1-day-old lens mRNA (ref. 9).

mRNAs or instability of the crystallin proteins characterise the $3\frac{1}{2}$-day eye cup.

The presence of low levels of crystallins in the freshly excised retina of day old chicks in the absence of detectable crystallin mRNA suggests that those crystallins which are synthesised during the embryonic period are not broken down.

Measurement of hybridisable crystallin mRNA in transdifferentiating $3\frac{1}{2}$-day embryo NR cultures shows that the levels attained in terminally differentiated cultures are similar to those achieved by 8-day embryo NR but these levels are reached by 3 weeks from the $3\frac{1}{2}$-day embryo[13,14] as compared to 6 weeks for 8-day embryo NR. These data, and the data presented here, suggest that mRNA and transdifferentiation potential are related, but we have not yet determined whether the change affects the numbers of cells expressing crystallin mRNA or the levels per cell. This is currently under investigation. Previous data have, however, indicated that some of the cellular conditions and manipulations favouring transdifferentiation exclude cell selection as a possible mechanism[1,4]. Many mRNAs normally coexist in cells, so it seems possible that the ease of differentiation along a particular pathway has a molecular basis in the relative levels of the mRNA appropriate to the end point in that pathway.

If low levels of crystallin mRNA are the preconditions for transdifferentiation into lens, (as we propose here), then cell dissociation followed by reassociation are the permissive conditions, and the directive conditions include cell culture medium, cell density, embryonic age and genotype, which all affect both the direction of transdifferentiation and the relative balance of the different crystallins ultimately synthesised. Evidence for these latter propositions is assembled and discussed more fully elsewhere[1].

A double-stranded β-helix with antiparallel chains in a crystalline oligo-L–D-peptide

E. Benedetti, B. Di Blasio & C. Pedone

Istituto Chimico, Università di Napoli, Via Mezzocannone 4, 80134 Napoli, Italy

G. P. Lorenzi, L. Tomasic & V. Gramlich

Technisch-Chemisches Laboratorium, ETH-Zentrum, 8092 Zurich, Switzerland

There is much interest in the ionophore-mediated and channel transmembrane transport of alkali metal ions. Valinomycin and gramicidin A, which is a linear pentadecapeptide with alternating L–D-residues, are classic representatives of carrier and channel-type ionophores, respectively, and their structure–function relationships are being intensively studied[1–4]. Helical structures for alternating D,L peptides have been proposed from conformational energy calculations[5–7], and from experimental spectroscopic data single-helical structures have been postulated for gramicidin A (ref. 8). Stereochemical and energy considerations[7,9] have suggested that polypeptides with alternating L- and D-amino acid residues may take up coaxial double-helical β-structures, both parallel and antiparallel, which are stabilised by systematic interchain NH....OC hydrogen bonds. Experimental results supporting the occurrence of structures of this kind have been obtained by Veatch, Fossel and Blout[2] for gramicidin A in nonpolar solvents, and by Lotz, Colonna-Cesari, Heitz and Spach[10] for poly-(γ-benzyl-D,L-glutamate) in the solid state. However, there has previously been no experimental determination of the detailed structural and conformational parameters characterising these structures. We now provide detailed conformational parameters of a double-stranded β-helix with antiparallel chains obtained by single crystal X-ray analysis of the model L–D peptide Boc-(L-Val-D-Val)$_4$-OMe (ref. 11).

The compound investigated crystallises from ethyl acetate solutions in the trigonal $P3_221$ space group with cell dimensions $a = 12.760$ Å, $c = 63.190$ Å and $d_{calc.} = 1.05$ g cm^{-3}, based on monohydrated units ($C_{46}H_{84}N_8O_{11}.H_2O$) and $Z = 6$. Data, collected on the Enraf–Nonius CAD-4 PDP 11/34 diffractometric system of the Centro di Metodologie Chimico Fisiche at the University of Naples, consisted of 6,399 measured reflections, 2,721 of which had a net intensity $>3.0\sigma$ (I). The structure was solved using Multan and has been refined by a least squares procedure, with isotropic thermal parameters for all atoms to an R factor of 0.13 for the observed reflections.

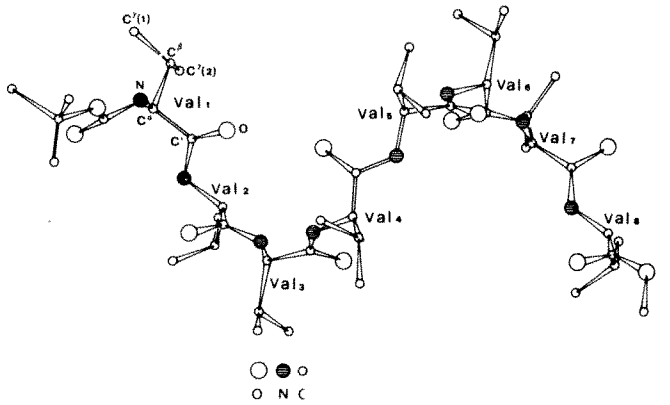

Fig. 1 Molecular model of Boc-(L-Val-D-Val)$_4$-OMe as viewed along the b axis. The eight valine residues are schematically indicated; only the first is labelled.

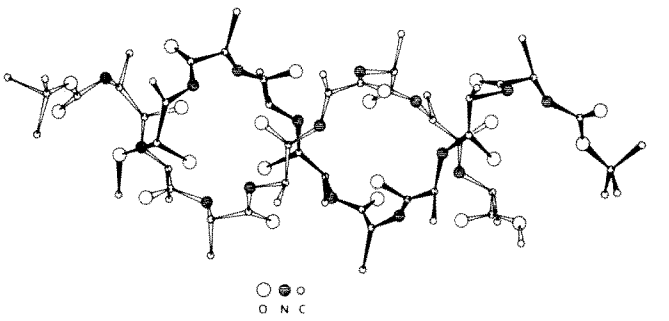

Fig. 2 The double-helical dimer as viewed along the b axis. The side chains are omitted from the model for clarity.

Figure 1 shows the molecular model of the octapeptide chain. Its structure consists of dimers (Fig. 2) in which each peptide chain is related to the other by a crystallographic twofold axis perpendicular to the helix axis, giving rise to a double-stranded, left-handed helix of antiparallel chains. Seven independent (14 in one dimer) NH....OC intermolecular hydrogen bonds link two antiparallel chains, with N....O distances of 2.7–3.0 Å. Only one potential hydrogen bond donor per chain is not involved in hydrogen bonding. The conformation of each chain can be described by the φ and ψ conformational parameters. They assume values in the range of $-148° \leq \varphi \leq -112°$ and $98° \leq \psi \leq 122°$ for the L-residues and $80° \leq \varphi \leq 129°$ and $-163° \leq \psi \leq -152°$ for the D-residues. Side chains assume different conformations for L- and D-residues; all four D-residues have the two methyl groups of the isopropyl moiety in g_+ and g_- conformations (close to $+60°$ and $-60°$) with respect to the N atom, whereas in L-residues the g_+, t conformation ($+60°$, $180°$) is observed three times and the g_-, t conformation ($-60°$, $180°$) only once. Along the axis of each dimer four distinct sections (about 4 Å apart) can be seen, in each of which four carbonyl oxygen atoms lying in a non-planar arrangement, could be available for possible coordination to metal ions within the core of the chain. The distance of each carbonyl oxygen from the chain axis is 2.5–2.9 Å. Projections along the dimer axis clearly show the steric hindrance produced by the N- and C-terminal blocking groups which partially close the mouth of the 'cylinder'. The water molecule is hydrogen bonded to the urethane carbonyl oxygen and a symmetry-related water molecule. All peptide linkages, as well as the urethane bond, occur in the *trans* configuration ($\omega = 180$), with maximum $|\Delta\omega| \leq 6$.

The dimer can thus be regarded as a cylinder with an hydrophilic inner core of almost planar peptide bonds nearly parallel to the chain axis, and an hydrophobic outer layer of isopropyl groups of the valyl residues. The length (from N_1 to C_8') and average inner diameter of the cylinder are 14.8 Å and 5.1 Å, respectively.

The double-helical structure of the dimer described here can be considered a stereochemical model of the antiparallel β-double helix proposed by Blout and coworkers[3] for species 3 of gramicidin A.

THE CHAIN STRAIGHTENERS
Fruitful Innovation – The Discovery of Linear and Stereoregular Polymers

FRANK M. McMILLAN

One of the most exciting stories in the history of Science – in the tradition of The Double Helix.

A narrative account of the remarkable burst of scientific discovery and technological innovation that gave science mastery over the 3-dimensional structure of high polymers and the world its most useful group of plastics and synthetic rubbers.
This book examines the personalities and the work of the key people involved and the controversies they aroused. Amongst these it pays particular attention to the seminal work of Karl Ziegler in Germany and Giulio Natta in Italy. This is a superb case study of the conditions under which fruitful innovation takes place; of the fortuity of many discoveries and their later rationalisation, of the continuity of science, the critical importance of alert observation, and the necessity of aggressive follow-up.
To be published in November by The Macmillan Press « £9.00 0 333 2529 7

AMBIO A JOURNAL OF THE HUMAN ENVIRONMENT

Now distributed for the Royal Swedish Academy of Sciences by Pergamon Press

Launched in 1972, AMBIO is already recognized by many as the leading interdisciplinary periodical in the environmental sciences.

Now, with the aim of broadening an already international coverage and readership, AMBIO will be published and distributed through a joint arrangement between the Royal Swedish Academy of Sciences and Pergamon Press.

Regular issues contain general articles on current environmental problems and challenges and reports on original research in the field. Special issues give a more comprehensive treatment of some topical subjects, e.g. issues are planned on the Baltic and threatened ecosystems.

" . . . The most authoritative journal of its kind on international environmental problems."
GILBERT F WHITE, *President, Scientific Committee on Problems of the Environment, I C S U*
" . . . AMBIO is the best magazine of its kind."
IGNACY SACHS, *Centre Nationale de Recherche sur L'Environnement*
"It conveys the message on crucial environment issues in the most accurate and well-presented way."
MOSTAFA K TOLBA, *Executive Director, UNEP*

New books from CAMBRIDGE

What Little I Remember
OTTO FRISCH

In this delightful autobiography the late Otto Frisch relates some of the most exciting developments of modern physics, including his discovery of nuclear fission, a term he himself coined. Professor Frisch describes vividly how he witnessed the unravelling of the double helix, the making of the first atomic bomb and the birth of radioastronomy. His entertaining anecdotes of the many great scientists he met during his lifetime create the background for his pen portraits and the many photographs included in the text.

'This is a happy book, from which the author's personality and his enjoyment of physics, of music, of life emerges clearly.' Rudolf Peierls in *Nature*

The Forces of Nature
P.C.W. DAVIES

Written in a lively and readable style this book presents an authoritative account of exciting developments in sub-atomic physics, making them accessible to a general audience. The reader will learn about antimatter, the creation and destruction of particles, the evidence that the celebrated quarks are fundamental building blocks for matter, and the promising signs that a unification of the basic forces of nature is at hand.

'Dr Davies's book is a lucid and elegant exposition of some of the most sophisticated theories and discoveries of modern science, and conveys a real sense of intellectual adventure and excitement.'
Coventry Evening Telegraph

Arch Bridges and their Builders 1735-1835
E.C. RUDDOCK

This book is a comprehensive history of an era in which bridge building spread rapidly throughout Great Britain. It is a highly readable and beautifully illustrated account consisting of narratives of individual bridge projects in which all the men involved come to life for the reader. All the bridges described are of interest as engineering works, while others are notable as works of outstanding architectural beauty and design.

'This superb classic is for all men and women to read.'
Journal of the Royal Institute of British Architects

This book has been awarded the Alice Davis Hitchcock Medallion for 1979 by the Society of Architectural Historians of Great Britain for its 'outstanding contribution to the study or knowledge of architectural history'.

CHRISTMAS BOOKS

The guiding star

W. H. McCrea

The Star of Bethlehem Mystery. By David Hughes. Pp. 218. (Dent: London, 1979.) £7.95.

THE story of the star of Bethlehem comes to us in the vivid words of Matthew 2: 1-12, and nowhere else in the *Bible*. The mystery in the title is that of the star's identity. If a disproportionate part of this review is taken by the reviewer's response to the challenge of David Hughes' interpretation, it is in tribute to the fascination of the book. That interpretation is as follows:

The year 7 BC saw the rare occurrence of a triple conjunction of the planets Jupiter and Saturn. As its most relevant consequence, it caused these planets to keep about one degree apart in the sky from mid-September to early December. The planet-pair during that interval was the 'star' of Bethlehem. In extant cuneiform texts, Babylonian astronomers had accurately predicted its observable behaviour. The Magi of the story were Zoroastrian priests schooled in such astronomy. At the time they shared a widespread expectation of the manifestation of a Messiah. Their sophisticated astrology made them take some — predicted or observed — feature of the behaviour to augur this Messiah's birth and to denote that it would occur amongst the Jewish people in the land of Palestine. Such was their conviction that a group set out to discover the child. They made for Jerusalem as the chief city of Palestine; there they created a stir by asking about a new-born 'king'. In consequence, King Herod directed them to Bethlehem. The 'star' reappeared, and somehow indicated their goal. There the Magi paid joyful tribute, and offered gifts which they had dedicated to this consummation.

Ruthlessly distilled, such is the account emerging from Hughes' comprehensive presentation of the astronomical and historical evidence. His astronomical conclusions are generally wholly convincing. However, there are difficulties in the account as a whole. First, as we shall see, it explains too much. Then, although Hughes has convinced me that he could have convinced the Magi that their own conventions would produce the suggested astrological prediction, there is no known evidence that the Magi made this prediction. Again, by inadvertently implying such a success for astrology, the account apparently resolves one mystery by creating a worse mystery.

Let us consider an alternative approach, and let us do so with reference to the version of the Matthew story in the *New English Bible*. The quoted passage is succinct; let us be the same. We proceed on the basis — to be tested — that it is historical. Matthew could not know the story from personal experience. He introduces the astrologers (as the Magi become in *NEB*) simply as "arriving" in Jerusalem. There is no suggestion that a star induced them to come, none that it guided them. So they came as ordinary visitors. We know there were periodical visits by "inhabitants of Mesopotamia" (Acts 2:9) and the like; we infer that the astrologers were amongst such visitors. But this particular visit turned out to be uniquely eventful; the homecoming participants would rehearse the tale until it became a set piece. Other visitors would carry it back to Jerusalem, and Matthew has passed it on to us. In confirmation, linguists remark how each mention of the star is in terms that astronomer/astrologists would use. Also, the passage is singular in that Matthew finds no prophecy to quote about the star. If the account is historical, we are thus most probably dealing with the astrologers' version.

When the account opens, it all but explicitly admits that the astrologers then knew about the birth of Jesus as something out of the ordinary. So they would cast about for a portent. An observed acronychal rising of a 'star' supplied it. Portents belonged to rulers, so the child was 'born to be king' — of the Jews, for he was in Judea. In spreading this notion, we cannot know how much the astrologers themselves believed. Anyhow it upset King Herod, who would tolerate no threat to his dynastic obsession. He asked his advisers about the birthplace of "the Messiah" — presumably trying to conceal his motive by not saying "king". Since Matthew has them replying in the identical words in which he had just recorded the birth of Jesus, he appears to tell us that they had knowledge of the birth; but they covered up by "referring" Herod to a prophecy about Bethlehem. He surreptitiously met the astrologers, interrogated them about the star, despatched them to Bethlehem, and ordered them to report back.

In Bethlehem, the astrologers found the "place where the child lay", and soon they "entered the house". In the intervening moments "they were overjoyed at the sight of the star . . . which they had seen at its rising". It was early evening because, although the star was visible, the hour was suitable for the strangers to visit the child and his mother. So the star had just "come out", and it could not have guided them on the way. Matthew does not say it did, but simply that it was there ahead of them. Granting that it was a real star, the sight would have been the same that evening anywhere else in Palestine, and much the same any other evening within days. But to astrologers a star would be of interest only if doing something special — like rising acronychally; or seen at a special moment — like this, when their pretensions were on trial. The astonishing sight at this moment of the self-same star that they had adopted as portent seemed miraculous confirmation of their claims, no matter how little faith they had in them — hence their rapture. So they entered, "saw the child with Mary his mother" and saluted him. The record says, "then they opened their treasures"; that they had to do this, between the salutation and offering gifts, implies that the turn of events had taken them by surprise. Then they went home; and that is the end of what we may take to be their own story.

Matthew's continuation shows that the astrologers evidently told Joseph of their intention to evade Herod. The simplest conclusion for Herod would have been that they had failed in their mission. His murderous reaction indicates that some rumour of their finding the child got round to him.

This narrative seems to overcome the difficulties found in Hughes'. It purports to account for nothing beyond what Matthew tells us. Although it takes account of the behaviour of astrologers as such, nothing depends upon any interpretation on their part beyond what is directly implied by the text as we have it, and nothing implies any success or benefit attributable to astrological prediction. The climax of Matthew's account of the astrologers in the slaughter of the Innocents is indeed a terrible indictment of their activities, as well as of Herod.

Certain possible difficulties mentioned by Hughes himself are also resolved. For instance, the fact that two and only two sightings of the star play any part is automatically explained. Also, as the first sighting is here held to have had nothing to do with the astrologers setting out for Jerusalem, it could have occurred any time up to their arrival; so it denotes no constraint upon the duration of their travels.

On the revised account, Babylonian astrological conventions carry less weight in attempts to identify the star. Nevertheless, purely astronomical

considerations, and elementary regard for what could interest astrologers, still seem almost overwhelmingly to support the identification with the planet-pair Jupiter and Saturn favoured by Hughes. Or it might be that 'the' star was just Jupiter, with the attendant Saturn making it more than usually noticeable or interesting for the time being.

The fact that the account can be so readily related to a known astronomical phenomenon, and its remarkable internal consistency, are strong evidence for its historicity. If both lines of evidence are accepted, they indicate that the Magi/astrologers went to Bethlehem in 7 BC sometime after mid-September, as Hughes would agree, but some of his other time-constraints may be relaxed somewhat.

It was David Hughes himself who, by his article in *Nature* (**264**, 513-517; 1976) on this most famous star of all, initiated the recent renewed interest of, particularly British, astronomers in the subject. In his book, he now surveys it in the widest possible setting. He reviews the results of an enormous amount of published scholarship in biblical and historical studies, in archaeology and anthropology of the Middle East, and in astronomy itself. Naturally, he takes full account of the discussions instigated by his *Nature* article. He has devoted acute critical and constructive thought to collating this vast material, with most illuminating results. He re-discusses probably every serious suggestion that has ever been advanced to account for the 'star' by astronomical phenomena or other natural processes. He writes with vigour and clarity, reinforced by numerous well-conceived tables and diagrams, happily-chosen plates, and a full bibliography. The wealth of background and sequential material is bound to make it harder to trace the central theme of the identity of the star and what it can tell about the birth of Jesus. However, most readers will be fascinated by it, as well as by this theme itself.

The planetary conjunction hypothesis regarding the star goes back at at least as far as Kepler. A leading modern exponent, particularly in regard to its setting in Babylonian astronomy is K. Ferrari d'Occhieppo, to whose valuable monograph *Der Stern der Weisen* (Vienna, 1968, second edition 1977) Hughes makes frequent reference. Hughes' book is the only full account in English, and I think it is the most comprehensive work by any astronomer on the subject of the 'star'.

The book inspires yet another line of thought. Questions of significance will be discussed for evermore. But, wherever possible, matters of simple fact should be settled once and for all. In regard to an important date, for example, it ought now to be possible to use a computer to sift all the evidence, test it for compatibility and so forth, and in at least some cases produce a uniquely acceptable solution. In other cases a computer might determine the date by predicting testable consequences of all reasonable hypotheses about it. The possibilities seem unbounded. □

Biological analogy

Martin Pollock

The Evolution of Designs: Biological Analogy in Architecture and the Applied Arts. By P. Steadman. Pp. 276. (Cambridge University Press: Cambridge and New York, 1979.) £9.50.

THIS book is essentially an analytical description of the evolution of design in the construction of human artefacts, being focused, as the subtitle indicates, on architecture and the significance of biological analogy in attempts to understand the principles involved.

The biological analogy is, indeed, a fertile and stimulating one and there is plenty of interest in how Professor Steadman pursues, criticises and finally rejects it as "false". Close comparisons between living organisms and man-made structures can be drawn at many different levels: the whole system designed "for a purpose"; classification of different but related types; structural anatomy (endo- and exoskeletons in both cases); ecology (form related to function and the environment); evolution (Darwinian versus Lamarckian); ornamentation (vestigial organs in plants and animals and so-called "skeuomorphs" in architecture that involve conversion of originally necessary features into purely decorative patterns); and many others, all considered in some detail.

During the course of this comparison, the author discusses various attempts to develop a general understanding of the principles of design over the past 150 years. Amongst these, particular critical attention has been paid to the general evolutionary doctrines of Herbert Spencer, to the fascinating "Purism" of Le Corbusier and Ozenfant, whose views on the basic banal forms they called "objets-types" (such as the bottle, tobacco-pipe, drinking glass, and so on) which, having completed their evolution to combine maximum utility with maximum manufacturing economy and acceptability (including aesthetic appreciation), correspond closely to Darwinian principles applied to artefacts; and, in more recent times, to Christopher Alexander whose views on the "unselfconsciousness" of the better designs in architecture are presented as being close to the biological analogy; and to David Clarke's *Analytical Architecture* (1968), which also argues against cultural systems having a "life of their own", considering them rather as part of biology, comprising "information systems of cumulatively acquired knowledge, partly replacing instinctive behaviour in man and selectively advantageous in his struggle for survival" (page 220).

All this is of great interest and value. But the style is rather heavy and the presentation somewhat confused — perhaps even misleading at times — largely because of this concentration on the significance, or otherwise, of a biological analogy. Indeed, the concept itself of *analogy* (defined in the *Oxford English Dictionary* as "resemblance of form or function without identity of essence") differs according to taste and habit. Sometimes it is simply a question of similarity without identity: for instance, most buildings, like many organisms, need light and insulation and internal structural support; they are inevitably subject to the same chemical, physical and mechanical forces of their environment and must therefore have features in common. A very different type of analogy is primarily anthropomorphic — sometimes to the point of being poetic fancy, such as the resemblance of the façade of a house to a human face. After all, man is always constructing models of what he perceives; and because he finds it hard to have totally new ideas, he is always making comparisons and extensions, usually with reference to human experiences already encountered. He will see himself and familiar objects in almost anything. To pay too much attention to analogy (in all its varied forms) in order either to discard or accept any particular interpretation can therefore be misleading. Its value, I would argue, is in helping to visualise alternative ways of approaching an understanding of a problem.

Philip Steadman rejects the "biological analogy" largely because the evolution of design, like other forms of cultural expression, is Lamarckian (that is, directly moulded by the environment) rather than Darwinian (due to selection of a very few types out of a huge number of possible variants) which is the currently accepted theory of organic evolution. Even here he admits that the situation is not perhaps as clear cut as might at first appear: successful designs *do* survive through some sort of selection, from a large variety, by human choice which acts as the controlling environment as well as the apparently direct source of the various designs. But most biologists would agree that cultural evolution, whatever its mechanism, does not involve the permanent stable change in DNA composition that occurs in the evolution of living organisms themselves. And Popper is quoted (page 216) as pointing out that if all literature and other types of artefact were totally destroyed, the

human race would have to start again almost from scratch. Only memory would remain and that would persist through generations only in so far as verbal transfer of information from one person to another continued. But we really know very little about human evolution over the last 50,000 years — that is, during the period when man himself has been modifying his own environment and so possibly directly affecting the manner in which the environment has been playing a part in his evolution, at least to an extent far greater than have other organisms.

This only emphasises another problem to be faced in the exploitation of biological analogy; namely the importance (and difficulty) of getting the biological situation right in the first place.

A simple example of this would, indeed, be Steadman's second argument for rejecting the Darwinian analogy (page 101) which is that cultural evolution is "reticulate"; that is, it combines elements from different origins and is therefore fundamentally distinct from the Darwinian "tree" in which the branches always diverge and never rejoin. Well-versed in biology generally, the author is not here up-to-date, as possible instances of "reticulate" evolution in biology are becoming more and more convincing and the prokaryotic origin of both the chloroplasts and mitochondria of eukaryotes is now generally accepted: a rather pretty analogy with (for instance) the common practice in early Islamic architecture of actually using (not just copying) pilfered Roman pillars for decorative support of vaulting such as that of the famous Omayyad mosque in Damascus.

But this is really neither here nor there in the study of the evolution of design generally. Reference to analogy is useful for hanging a discussion upon but, in the last resort, the relevant processes have to be analysed in terms of the direct influences that operate. And the problem centres on the extent to which man's activities can be considered to be simply one aspect of the way some organisms operate: strictly a problem in biology, complicated though that may be. The opposite approach, favoured by Professor Steadman, is that man's cultural expression must be studied, at least some extent, in its own right: there is such a thing as design *per se*; it is the result of conscious mental activity and cannot be reduced by scientific dissection to analysis in strictly biological terms. And from that angle one is plunged (if not explicitly) into all the deep conundra that have plagued philosophers from time immemorial: determinism, intrinsic free-will, reductionism, dualism, and so on.

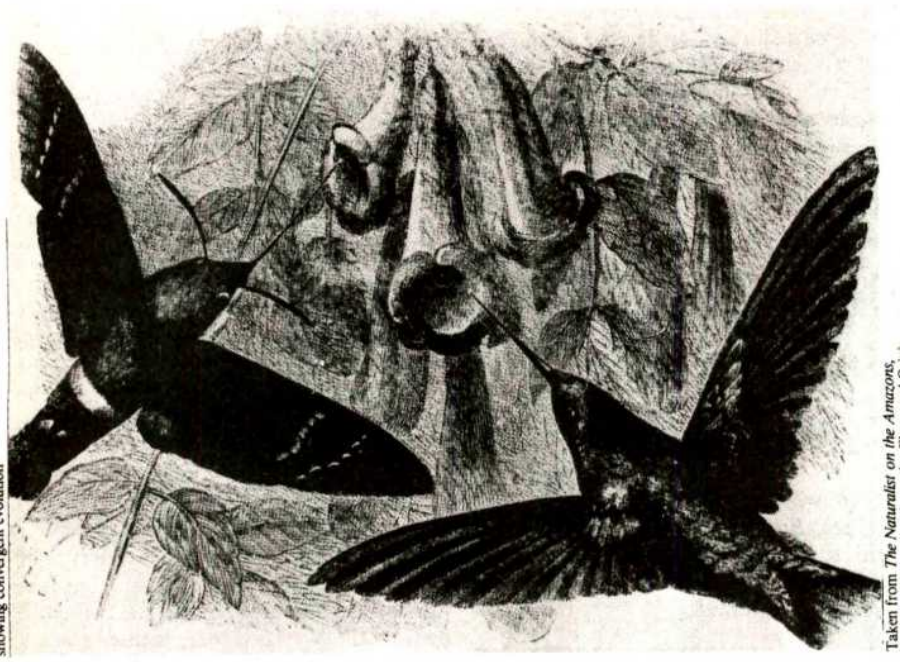
At the end, the author asks the question: "What are the features or properties of artefacts of all kinds to which scientific study should be directed and about which scientific prediction might be made?" (page 238). To the question: "Can design be made scientific?", he answers that at least *some* features are beyond scientific attack. A closely related and even more critical question might be: "To what extent do we need to study the subjective thoughts and feelings of human beings — as distinct from what they *do* (which is how we study other organisms) — in order to understand the history of processes such as the evolution of design?". And if the former seems important we may further ask: "How do we do it?" and then: "Can we do it scientifically?". □

Martin Pollock is Emeritus Professor of Biology, in the University of Edinburgh, UK.

New English *Origin*

Richard Dawkins

The Illustrated Origin of Species: An Abridged Edition of the Sixth Edition. Abridged and introduced by Richard E. Leakey. Pp.240. (Faber and Faber: London, 1979.) £8.95.



An invitation to review the *Origin of Species* in *Nature* is too much for the humble modern biologist to pass up. What line to take? "Would be better if he had stuck to pigeon breeding?" No, that's been had before. "Sexist, and unconsciously favours the status quo?" Better, but those in a position to see the funny side haven't the sense of humour to do so. "Cannot be saying anything very profound, since any layman can understand him?" Ah, but that does not mean that any *fool* can understand him. On the contrary he has been comprehensively, comically, misunderstood by many who were not laymen and not fools. The patient effort Darwin put into advocating his thesis, the persuasive, cogent clarity that he achieved, lead one to the salutary realisation that ideas do not have to be formidably complex, smothered in mathematical barbed wire, in order to be utterly incomprehensible to unprepared minds. They only have to be revolutionary. But this reviewer is getting above himself. It is his humbler task to review a pleasing picture book for the Christmas coffee-table market.

In a sense, everything is in the idea. Once you have *thought* of producing an illustrated *Origin of Species*, the rest is money for old rope. Well, and scissors and paste and a lot of hard work phoning round to the photographic agencies. I would certainly like to salute the unnamed employee (or ex-employee) of the Rainbird Publishing Group who thought of it. If ever an illustrated book conjured up vivid pictures in the mind of the reader, it is the *Origin of Species*. Darwin wrote before colour photography was invented, and he included only one technical diagram in his book. But he was such a passionate advocate, such a tireless seeker after honest ways to make his meaning plain to everyone, that I cannot doubt that he would have welcomed all the visual aid that modern photography can offer.

The idea, then, is an excellent one, and I find nothing irreverent or reprehensible about putting it into practice, except insofar as it may pre-empt later bites at the same cherry. It is, evidently, an idea whose time has come, a hot property in the publishing world. Only about a year ago I recall a colleague, who had been invited by a publishing company to edit a similar illustrated *Origin*, discussing how he might do it. An artist as well as a scientist, he saw the task as a labour of love for Darwin, and he would have used only contemporary Victorian illustrations. I (who coincidentally and simultaneously had been invited to edit an illustrated *Origin of Species* by yet another publisher!) was more of the Leakey school of thought. If Darwin had wanted to illustrate his book with Victorian prints, I suggested, he could have done so himself. I would have used modern pictures, as technically perfect as I could find. I think Darwin would have appreciated that labour of love more, and I am glad that Leakey and the Rainbird team elected to do it that way. My colleague and I, incidentally, both declined our invitations, but I still have the notes I made as I reread the *Origin* with illustrations seriously in mind, and it was consequently of absorbing interest to me to see how Leakey and Rainbird had actually done it.

I think they have done it rather well. In addition to excellent black and white and colour photographs, they have used artistic drawings and paintings, clear maps and diagrams, and even a few Victorian prints. The captions are well done, frequently beginning with a relevant quotation from Darwin's text and ending with an up to date comment from Leakey. Someone who simply browsed through the pictures would come away with a good feeling for the diversity and complexity of life, with a sense of something needing to be explained which might inspire him to read the text.

I am less happy with the fact that Leakey has comprehensively bowdlerised the text into a kind of *Reader's Digest* version. No doubt some cuts were necessary; I am sure Leakey has succeeded in his stated aim of eliminating Darwin's "tendency to Victorian wordiness", and that he can be trusted to "in no way change Darwin's original meaning," but even so! This may be the only copy of the *Origin* that many people possess, and they will want to be able to refer to, or quote, exactly what the man said. It might be thought that the problem could have been solved by indicating omitted passages by dots, and

Humming-bird hawk-moth and humming bird, showing convergent evolution

Taken from *The Naturalist on the Amazons*, by Henry Bates, and from the *Illustrated Origin*

this would have been so if Leakey had contented himself with cutting out definite large chunks or whole chapters. But in fact he has done such a thorough (and actually rather good) editing job that scarcely a single sentence is exactly as Darwin wrote it, and the pages would have become a sea of dots. Leakey insists in his Introduction that, in making these cuts, he has not "tried to make Darwin more modern than he was, since he can stand on his own feet." But consider the very first whole sentence omitted: "There is, also, some probability in the view propounded by Andrew Knight, that this variability may be partly connected with excess of food." Darwin was wrong here, and the omission of the sentence (with no indication that anything has been cut) cannot fail to make Darwin seem more modern than he was. Darwin can stand on his own feet, certainly, and he doesn't need that kind of help.

Turning to the rest of the Introduction, I sympathise. The *Origin of Species* must be one of the most introduced books in science, and the supply of original things to say must be running low. In the circumstances Leakey does what I would have done, and contents himself with a smooth and unexceptionable record-sleeve job, a little standard history and a little modern biology, especially genetics, bringing us up to date on what has happened since Darwin's time. For me, as, I think, for Leakey, reflection on such matters has the odd effect of underlining Darwin's own remarkable prescience. He was, in Michael Ghiselin's words, "a genius of the first rank and a man of immense learning and he often worked a century or more ahead of his time." Natural selection theory is in an exciting and fast-moving phase just at the moment, but in many respects the 'revolutionary new' insights of the 1960s and '70s represent a rediscovery of something that had been lost — Darwin's own uncompromising grasp of the ruthless individual struggle in the economy of nature.

For this reason I am slightly sorry that Leakey chose the sixth edition as the basis for his abridgement. The first edition, though not Darwin's parting shot on the subject, is of greater interest, both historic and scientific. It is of greater historic interest as the version that actually hit the Victorian solar plexus. But, paradoxically (this, too, is not an original point!), it seems scientifically more advanced than the sixth edition. The sixth edition includes Darwin's attempts to rebut contemporary objections to his thesis. These objections now have a fusty, dated air, and Darwin's replies to them inherit the same old-fashioned feel, something that the first edition, in its freshness, does not have. As is well known, Darwin's attempts to grapple with objections such as those of the great physicist Lord Kelvin, led him up the Lamarckian garden path much further in the sixth edition than in the first. Kelvin's calculation suggested that the Earth simply was not old enough to allow the evolutionary process that Darwin postulated. Darwin, humble non-mathematician that he was, had to accept Kelvin's authority and this led him into erratic special pleading. As Eisely has remarked, "today there is a tendency in some quarters to regard the physical sciences as superior in reliability to those in which precise mathematical adeptness has not been achieved. Without wishing to challenge this point of view, it may still be worth a chastening thought that, in this long controversy extending well over half a century, the physicists made extended use of mathematical techniques and still were hopelessly and, it must be added, arrogantly wrong". Darwin had been right all along, in the first edition, and the objections to his theory that he anticipated and refuted in the first edition have proved the durable ones that we still meet. Leakey actually seems to have an impoverished view of the first edition: he says that Darwin, faced with the difficulties of natural selection, "began to search for additional mechanisms. Darwin wrote another book about one of these accessory mechanisms — sexual selection — and he discussed it briefly in the sixth edition of *The Origin of Species*." This seems, wrongly, to imply that the first edition lacks the section on sexual selection.

The illustrations in this book are well chosen and attractively presented. Even if they were not, it would be hard for the formula to fail. Open the *Origin of Species* anywhere, and you immediately feel you have walked into the presence of a timeless master, whose location in the Victorian era would be hard to guess but for his ignorance of Mendelism and his odd deployment of commas (which, now that I think about it, Leakey also seems to have taken it upon himself to correct). To complete my quotation from Ghiselin, "What a pleasure it is to bask in the sunlight of his intellect". The pictures don't spoil my pleasure, and if they help to spread some sunlight over the coffee-tables of Christmas I am all for them. □

Richard Dawkins is Lecturer in Zoology at the University of Oxford, and a Fellow of New College, Oxford, UK.

Highly popular science

THERE will be little in *Scientists at Work: The Creative Process of Scientific Research* (edited by John Noble Wilford; Dodd, Mead: New York; $9.95), a collection of articles by journalists from the *New York Times*, that will be recognisable to working scientists. The articles are short, superficial, uncomfortably chatty and devoid of any critical approach to their subject. The writing is of the "Chilly winds howled across a massive stone overhang where a band of Stone Age hunters huddled around a campfire" type. The actual steps of the tedious construction of the elements of Stone Age life are omitted in favour of flowery and simplistic imagery. And it is the same throughout this collection of the "highly popular" *Scientists at Work* series which "introduces a world rarely seen or imagined by non-scientists".

Why is science reporting so bad? The editor informs us that none of the nine authors have less than ten years reporting experience. In addition we find that no effort or expense was spared to get the stories. "Interviews . . . extended over a period of several days" and the work involved "staying up all night at Kitt Peak

Studies in Archaeological Science

Principles of Archaeological Stratigraphy

Edward C. Harris

December 1979/January 1980, xii+136pp., £8.00/ $18.00 0.12.326650.5

This book is not only the first to set down the basic principles of archaeological stratigraphy; it also contains many new ideas on the subject. In particular, the use of the Harris Matrix, a method for analysing and recording archaeological stratification which was invented by the author in 1973. The book has three main sections. The first examines the historical development of some aspects of geological and archaeological ideas on the theory of stratigraphy, including the excavation and recording of stratification on archaeological sites. The second part considers the individual characteristics of archaeological stratification and methods by which it is recorded and its post-excavation analysis. The final part of the book is a series of appendices outlining modern recording procedures, a brief discussion of the development of the Harris Matrix and a glossary of terms used in archaeological stratigraphy.

Biological Techniques Series

Time-Lapse Cinemicroscopy

P. N. Riddle

October 1979, xiv+122pp., £8.50/ $18.00 0.12.588060.X

The realization of the analytical powers of time-lapse cinemicroscopy, with the increasing emphasis on quantitation, is a relatively new development. Dr. Riddle's work in organizing a highly efficient cinemicroscopy service for cancer research places him exactly in an authoritative position to present this account of apparatus, techniques and their applications. Dr. Riddle's approach is unusually valuable because he looks in detail at a range of instrument types, explaining their interdependencies and linking this to an exploration of how standard techniques may be included in cinemicroscopy. His inclusion of many references indicating where specialized uses may be followed up is most useful. Constructive discussion throughout the text is complemented by frequent references to potential problems and their possible remedies.

The Institute of Mathematics and its Applications Conference Series

The Mathematics of Hydrology and Water Resources

edited by E. H. Lloyd, T. O'Donnell and J. C. Wilkinson

October 1979, xii+138pp., £8.80/ $18.50 0.12.453350.7

Hydrology and water resource engineering are areas which have until very recently enjoyed a lesser degree of support from professional mathematicians than have many of the more traditional engineering disciplines. This conference was arranged with the advertized aim of encouraging communication and interaction between hydrologists and mathematicians, and improving and extending the application of mathematical techniques to problems of hydrology together with the neighbouring fields of civil engineering, meteorology etc.; and mathematics, together with probability and statistics. The main aim of the work is to combine complementary approaches by applied mathematicians and practising engineers for the assistance and edification of water engineers and those carrying out research and advanced studies in hydrology and applied mathematics.

Antibiotic Interactions

edited by J. D. Williams

December 1979/January 1980, xii+184pp., £10.00/ $23.00 0.12.756350.4

The publication of these proceedings marks the first of an occasional series of meetings concerning various aspects of infection which are being held under the sponsorship of Beecham Research Laboratories and are entitled The Beecham Colloquia. The series aims to create the opportunity for multi-disciplinary discussions into various key facets of the control of infection. This first meeting was held at the Medical Society of London and brought together 24 participants from Europe and America. They discussed the development of antibiotic combination therapy and the role of such therapy in the management of infection in man. Ten papers were presented giving up-to-date information and expert opinion on antibiotic interactions and the advantages and disadvantages of combined therapy. A great deal of the subsequent discussion has been included in this book.

Special Publications of the Society for General Microbiology 2

Adhesion of Microorganisms to Surfaces

edited by D. C. Ellwood, J. Melling and P. Rutter

December 1979/January 1980, viii+216pp., £10.00/ $23.00 0.12.236650.6

The problem of bacterial adhesion to surfaces is a rapidly expanding field of interest with great relevance to many diverse areas, from medical and dental research to soil science, from marine fouling to the fermentation industry. This book, which is the second in the series of publications arranged by the Society for General Microbiology, is a timely review of the subject and attempts to introduce a physico-chemical approach to the problem. The contributions are based on papers presented at a joint meeting between the Cell Surfaces and Membranes Group and the Ecology Group of the Society for General Microbiology, and the Microbiology, Fermentation and Enzyme Technology Group of the Society of Chemical Industry. The book starts with two review chapters, the first describing the physical chemistry of adhesion related to small particles, and the second discussing bacteriological aspects of adhesion. The subsequent chapters describe particular situations where bacterial deposition and accumulation is a problem. The final chapter is a provocative discussion of bacterial adhesion to eukaryotic host cells.

Neoplastic Transformation in Differentiated Epithelial Cell Systems *in vitro*

edited by L. M. Franks and C. B. Wigley

December 1979/January 1980, xii+312pp., £14.40/ $33.50 0.12.266260.1

This monograph offers the first review, with much unpublished new information, of some of the epithelial transformation systems now in use in the study of carcinogenesis. Originating from an Imperial Cancer Research Fund workshop for scientists working in the field of epithelial carcinogenesis, it presents papers given at that event and other invited contributions. As well as reviewing recently developed systems, some of the technical problems encountered are outlined and possible future developments are discussed. In short, it provides a survey of the present state of our knowledge of this important new branch of the study of carcinogenesis and offers a useful introduction to the field for fugitives from the fibroblast. Cell biologists, biochemists and molecular biologists, and particularly cancer researchers cannot fail to find this stimulating volume of much interest in their work.

Society for Applied Bacteriology Technical Series No. 14

Identification Methods for Microbiologists **Second Edition**

edited by F. A. Skinner and D. W. Lovelock

December 1979/January 1980, xii+312pp., £14.80 $34.50 0.12.647750.7

Since its original publication in 1968 as volumes 1 and 2 of the Society for Applied Bacteriology's Technical Series, *Identification Methods of Microbiologists* has proved beyond doubt to be of most practical value to the scientist when identifying particular groups of microorganisms. Many significant advances have been made, since then, in identification methods for certain genera and there have also been some changes in the taxonomic structure of some genera following the publication of the new Bergey's Manual in 1974. This second edition brings up-to-date in one volume chapters from both parts of the original edition, enabling the practical microbiologist to use the most recently established methods of identification.

Nature and Origin of Carbohydrates in Soils

M. V. Cheshire

December 1979/January 1980, viii+216pp., £15.80/ $36.50 0.12.171250.8

This volume examines the methods which have been devised to overcome the unique problems of isolating, purifying and characterizing carbohydrates in soils. A number of recommended procedures are given in detail and the physical and chemical properties of the isolated polysaccharides, including structure studies, are described. This account of soil carbohydrates is not restricted to their chemistry but includes discussion of the effects of climate, various agricultural practices, the decomposition of microbial and plant remains and the synthesis of new carbohydrate. Although primarily a reference work for soil scientists, agronomists and workers in related subjects, it is hoped that this book will provide a stimulus to further research on this vital area of soil fertility.

European Monographs in Social Psychology No. 18

Towards Understanding Relationships

Robert A. Hinde

December 1979, xii+370pp.
Hardback: £15.80/ $36.50 0.12.349250.5
Paperback: £7.80/ $18.00 0.12.349252.1

A science of interpersonal relationships which comes to terms with the dialectic between personality and relationships on the one hand, and that between relationships and the social environment on the other, could provide a strong link between diverse branches of social science. One section of the book is concerned with an initial requirement for such a science: an adequate descriptive base. Another main section explores a number of areas which may yield principles for understanding how relationships work or fail to work: studies of relationships in the context of a social group; dissonance and balance theories; learning, exchange and interdependence theories; and relationships seen as systems involving positive and negative feedback. Principles from each of these areas are related to the descriptive base. Finally, some developmental aspects are considered.

Constructs of Sociality and Individuality

edited by P. Stringer and D. Bannister

November 1979, xiv+350pp., £17.20/ $41.00 0.12.673750.9

This is the first book in its field to examine systematically the implications of Kelly's personal construct theory for social psychology. The origins of the work can be found in the papers presented at the 2nd International Congress on Personal Construct Theory (1977). Five of these papers — rewritten and expanded — have been included in this volume. The remainder were written especially for this volume with the exception of Kelly's "Social Inheritance" (1930).The book is divided into three sections, covering theoretical and meta-theoretical implications, the value of methods derived from the theory — for example grid method in socio-psychological fields — and finally a number of exemplary research studies. Many contributions to the work focus particularly on applied fields in social psychology covering such areas as politics, education, psychotherapy, relationship formation, social skills, and the law and rule systems.

Physical System Modelling

P. E. Wellstead

December/January 1979, x+280pp., £18.00/ $41.50 0.12.744380.0

All naturally-occurring physical systems use and process energy; the perceived dynamical behaviour of any system is simply the outward manifestation of this energy transaction. Whilst this notion of energy as a unifying agent is not new, Dr. Wellstead uses it here for the first time as a framework within which to study the various techniques of system modelling. The main part of the text is, therefore, devoted to the established methods of network analysis, variational analysis and bond graph analysis. Some highly specialized areas are excluded to enable the author to introduce a series of case studies that are designed to underline the link between the modelling process and subsequent simulation, design or control studies.

Chemical Thermodynamics

M. L. McGlashan

December 1979/January 1980, xx+345pp., £18.00/ $41.50 0.12.482650.5

This is a book written for chemists by one of the world's leading experts in chemical thermodynamics. Unlike other accounts of the subject, it stresses the fact that thermodynamics is an experiemental field, yet one that is securely founded on exact algebra. Linking these two aspects, Professor McGlashan demonstrates how all the equations of chemical thermodynamics can be deduced from a few axioms and how the physical quantities symbolized in those equations can be measured in the laboratory. Starting out with the aim of showing how and why thermodynamic equations are so useful to chemists, the author discusses those instances when simplifying approximations can usefully be made, whilst indicating the dangers of over-simplifying the notation. The book covers the strengths and limitations of classical thermodynamics, excluding such topics as electromagnetic, gravitational and relativistic effects (which are of little relevance to the chemist) and going beyond classical thermodynamics to discuss Boltzmann's distribution law and galvanic cells.

Symposia of the Zoological Society of London No. 44

Fish Phenology:

anabolic adaptiveness in teleosts

edited by P. M. Miller

December 1979/January 1980, xvi+450pp., £22.40/ $52.00 0.12.613344.1

The great scope of fish phenology is clearly demonstrated in the present volume. Basic topics include treatment of energy partitioning, accumulation, endocrine control, and response to environmental influences. The timing, magnitude, and fecundity of reproductive commitment is discussed for some of the many ecotypes successfuly occupied by the teleosts. A wide range of habitats from savannah pools to the deep sea are considered, as well as phenological modifications required by the migratory life-style of salmonids, seasonality in tropical habitats, and the diminutive adult size seen in many familiar aquarium fishes. Two important areas of fish phenology, not often reviewed, have also been included. These concern the nature of senescence, affecting the duration of individual anabolism, and the genetic transmission of growth and reproductive characteristics.

Na, K-ATPase: Structure and Kinetics

edited by J. C. Skou and J. G. Nørby

October 1979, xii+538pp., £22.50/ $52.00 0.12.647650.0

Since the first international conference on Na, K-ATPase was held in New York in 1973 a lot of new information has been gathered about what one contributor referred to as "this mischievous enzyme system". In order to meet and exchange views a second international conference was held in September 1978, in Denmark on the occasion of the 50th anniversary of Aarhus University. The present volume contains the papers that were presented at the meeting. In the editors' view the book gives a fair account of the present status in the field and, perhaps more importantly, it stresses the problems to be solved before it is understood how energy from the hydrolosis of ATP by this system is converted into transport work. As such it will serve as an extremely useful reference book for future work in the field, and particularly for biologists with a special interest in membranes, ion translocation and ATPase reactions.

Annual Reports on NMR Spectroscopy

Volume 9

edited by G. A. Webb

December 1979/January 1980, x+426pp., £25.00/ $57.50 0.12.505309.6

The major aim of this series is to provide timely accounts of those areas of NMR spectroscopy where significant advances are being made. In recent years the advent of FT-NMR techniques have shifted the emphasis away from ^{1}H NMR towards less receptive nuclei such as ^{13}C and ^{15}N which are now being studied routinely in many laboratories. This shift and the advances being made in the theoretical interpretation of NMR parameters are reflected in this series. In this latest volume, two aspects of the technique discussed in previous volumes are extensively reviewed and brought up-to-date, namely, the NMR of paramagnetic species and heteronuclear magnetic double resonance. Also discussed for the first time is ^{29}Si NMR and recent work on the less common quadrupolar nuclei.

Probability and Mathematical Statistics: A Series of Monographs and Textbooks

Multivariate Analysis

K. V. Mardia and J. T. Kent

December 1979/January 1980, xvi+518pp., £26.40/ $61.00 0.12.471250.9

Broadly speaking the first half of the book contains direct extensions of univariate ideas and techniques, including exploratory data analysis, distribution theory and problems of inference. The remaining chapters concentrate on specifically multivariate problems which have no meaningful analogues in the univariate case. Topics covered include econometrics, principal component analysis, factor analysis, canonical correlation analysis, discriminant analysis, cluster analysis, multidimensional scaling and directional data. Several new methods of presentation are used. For example, the data matrix is emphasized throughout, a density-free approach is given to normal theory, tests are constructed using the likelihood ratio principle and graphical methods are used in explanation.

Proceedings of the Serono Symposia Volumes 20A and 20B

Emotion and Reproduction

edited by L. Carenza and L. Zichella

Volume 20A: November 1979, xx+684pp., £29.50/ $62.00 0.12.159401.7
Volume 20B: December 1979/January 1980, xx+734pp., £29.50/ $62.00 0.12.159402.5

The complex interactions of physiological, psychoneurological, social and cultural factors involved in human reproduction, necessitate an interdisciplinary approach. The 5th International Congress of Psychosomatic Obstetrics and Gynecology, the proceedings of which are presented in these volumes, brought together experts in all these disciplines. In addition to the more traditional topics in reproduction research, the discussions in the first volume cover fertility control, including the approaches to contraception in a number of different cultures, the psychological effects of sterilization, and the role of sexuality and certain behaviour patterns in reproduction. The second volume covers the psychological effects, both for the mother and the child, of the experience of birth; pregnancy and delivery; pain in labour; breast feeding and the bonds with the mother, and the methods of preparation and assistance at birth.

Hormones and Evolution

editied by E. J. W. Barrington

Volume 1: November 1979, xxvi+512pp., £30.00/ $69.00 0.12.079401.2
Volume 2: December 1979/January 1980, xxvi+518pp., £30.00/ $69.00 0.12.079402.0

One theme now prominent in contemporary biology is that of the remarkable adaptive diversity of organisms and the unity that underlies the evolution of this diversity. This two-volume work concentrates on research in this area, bringing together 28 internationally recognized authorities who present, in a broad evolutionary context, comprehensive and critical reviews of the information now available in many areas of comparative endocrinology. With attention concentrated on the hormones themselves, rather than on the glands that secrete them, they show where important advances are being made, and indicate the paths along which new research could profitably be directed. The wealth of authoritative and up-to-date information presented in these two volumes, and accompanied by extensive bibliographies, will make them indispensable to students, teachers and researchers in endocrinology, physiology, genetics and evolution.

Azotobacteraceae:

The Taxonomy and Ecology of the Aerobic Nitrogen-Fixing Bacteria

J. P. Thompson and V. B. D. Skerman

December 1979/January 1980, c450pp., £32.00/ $74.00 0.12.689050.1

In view of its potential economic value, research on all aspects of biological nitrogen fixation is progressing rapidly, and the publication of this thorough systematic study of the aerobic, non-symbiotic, nitrogen-fixing Azotobacteraceae, is indeed timely. The authors assembled a comprehensive collection of strains, using both local isolates and important type and reference strains from collections throughout the world, which were then examined systematically for a wide range of morphological, nutritional, physiological, biochemical and resistance attributes. The combination of the classic, systematic method with the modern, numerical analysis based on a comprehensive new set of experimental data, provides a unique treatment of this family which may serve as a model for similar treatises of other bacterial families.

Advances in Botanical Research Volume 7

edited by H. W. Woolhouse

December 1979/January 1980, xii+698pp., £35.00/ $80.50 0.12.005907.X

The aim of this series is to present authoritative statements in specialized fields of botanical enquiry which are currently in the process of rapid development. Each author places his own work against the general background of research in other laboratories and attempts to outline the possible direction of future developments, expressing his own opinions freely about controversial matters. Although the articles are primarily reviews, several in this volume contain substantial new results, for example the chapter on sodium nutrition in C_4 plants and the discussion on the rapidly-expanding subject of the physiology of orchids. These lively articles provide challenging and informative reading for all botanists whatever their speciality, at advanced undergraduate and research levels.

The Systematics Association Special Volume No. 14

Bryophyte Systematics

edited by G. C. S. Clarke and J. G. Duckett

December 1979/January 1980, x +582pp., £40.00/ $92.00 0.12.175050.7

There is in particular a great deal of new information which has a bearing on the systematics of the bryophytes and this book, the proceedings of an international symposium, organized jointly by the Systematics Association and the British Bryological Society, examines the present state of the subject. The 22 contributions show how recent research has confirmed or changed traditional ideas about the relationships and phylogeny of the wide range of plants that compose the Bryophyta. This volume therefore presents a unique synthesis of the current state of bryophyte systematics which will not only provide a useful and much-needed reference for students, teachers and research workers, but also, because of the critical approach to this complex subject, provide a stimulus to further research.

The Genus *Penicillium* and its Teleomorphic States *Eupenicillium* and *Talaromyces*

John I. Pitt

January 1980, c500pp., £40.00/ $92.00 0.12.557750.7

This is a comprehensive and authoritative revision of the taxonomy of the fungal genus *Penicillium* — the first for 30 years. Revisions of the ascocarpic genera producing *Penicillium* imperfect states — *Eupenicillium* and *Talaromyces* — are also included. The status of all *Penicillium* species described in the literature, now numbering nearly one thousand has been assessed, including the one hundred and eighty reported since the Rapet and Thom *Manual of the Penicillia* was published in 1949. From detailed comparative studies of all known types and other authenticated cultures, together with thousands of fresh isolates, a total of one hundred and fifty *Penicillium* species are recognized together with thirty-seven in *Eupenicillium* and sixteen in *Talaromyces*. For each accepted species is provided a description taken from colonies grown under standardized conditions of medium, temperature and incubation time, in conjunction with illustrations of colony appearance and microscopic morphology. Keys to all recognized species are also provided.

Announcing a New Journal from Academic Press

JOURNAL OF HOSPITAL INFECTION

Editor: G. A. J. Ayliffe
Hospital Infection Research Laboratory
Dudley Road Hospital, Dudley Road, Birmingham, England

Assistant Editors: P. D. Meers, P. Sanderson, D. C. Shanson

Editorial Board

A. Balows, J. Bennett, R. Blowers, M. W. Casewell, F. Daschner, H. Gaya, G. L. Gibson, O. M. Lidwell, E. J. L. Lowbury, W. Newsom, B. Nystrom, M. M. T. Parker, G. Reybrouck, M. Rotter, J. D. Williams.

Publication: Quarterly

Subscription: Volume 1, 1980
£19.50 (UK) $57.00 (overseas)

The changing pattern of hospital acquired infection and its prevention continues to cause problems. Prevention of spread of antibiotic-resistant strains of bacteria, the increasing use of immuno-suppressive drugs, and of complex heat-labile medical equipment have all provided new problems for clinicians, nurses and infection control staff. Infection control will have to improve as legislation imposes stricter standards.

It is hoped that the journal will promote collaboration between the different disciplines involved in infection control in many countries, and will particularly encourage the publication of scientific studies. It will publish original articles on all aspects of hospital acquired infection and its prevention. This will include surveillance, epidemiology, aseptic, hygienic and isolation techniques, disinfection and sterilization. Review articles, letters, short articles on special problems or outbreaks of special interest, questions and answers, and book reviews will also be published. The journal should be of particular interest to hospital microbiologists, epidemiologists, infection control nurses, environmental health personnel, infectious diseases consultants, as well as surgeons, paediatricians and clinicians working in high risk units such as intensive care, leukaemia, transplant and dialysis.

Please direct your enquiries to the Publisher at the appropriate address given below.

Gaia

A New Look at Life on Earth
J. E. Lovelock

'This is the most fascinating book that I have read for a long time . . . . Lovelock writes beautifully. A book that is both original and well written is indeed a bonus . . . . Only a genius thinks of the obvious and Lovelock deserves to be described as a genius. He has the same ability as the late August Krogh to throw out bright ideas in quick succession, each one of which would have satisfied most men for a long time.' *New Scientist.* £4.95

Applied Semigroups and Evolution Equations

A. Belleni-Morante

This is an introduction to the theory of linear semigroups and of linear, semilinear, and quasilinear evolution equations with particular emphasis on applications. It is intended as an introductory course for final-year undergraduate and graduate students, as well as for physicists and applied mathematicians who wish to see how an abstract theory can be used in connection with concrete problems. £9.75 *Oxford Mathematical Monographs*

Auditory Investigations

The Scientific and Technological Basis
Edited by H. A . Beagley

This book is intended for the wide and increasing body of professionals who are concerned with otology, audiological medicine, and audiological science. It provides a review of current techniques for carrying out investigations and research into the problems of hearing and hearing loss, and gives full attention to the most recent work. £35 *Oxford Medical Engineering Series*

An Introduction to Human Biochemistry

C. A. Pasternak

The aim of this book is to present in one volume the biochemistry and cell biology necessary for an understanding of the molecular basis of medicine. In so far as human biochemistry is studied in order to relate it to human disease, the book explains in molecular terms the basis of that relationship, and thus provides a useful introduction to the subject for all preclinical medical students, nurses, and biology students taking courses in Biochemistry. Illustrated £14.50 paper covers £6.95

Dear Health-Conscious

You care about the way you look. You feel fitter without those extra pounds and inches. Last year, HMSO published a reference booklet to help you make a well-informed choice about your diet. Already it has sold 49,000 copies. A further 7,500 are now being printed.

"Eating for Health" sets out what is known about food and its effect on your body. Topics covered include height, weight and food; how the body uses food; breast feeding; expectant mothers; vitamin deficiency diseases; slimming aids; coronary heart disease; convenience foods; and young children and adolescents. A reference book you cannot be without and its only 95p!

ISBN 0 11 320665 8 84pp **95p** *(By Post £1.08)*

Another HMSO publication you may be interested in is **"Doctors Talking to Patients.** *A Study of The Verbal Behaviour of General Practitioners Consulting in their Surgeries."*

This study of GP's verbal behaviour provoked much discussion in 1976. It is still very much to be taken to heart.

ISBN 0 11 320652 6 196pp **£3** *(By Post £3.25)*

HMSO BOOKS

Both publications are now available from:
HMSO, PM1C,
Freepost,
London EC1B 1DD (N.T.)
(no stamp needed).

We look forward to hearing from you.

DIGITAL METHODS FOR SIGNAL ANALYSIS

K. G. Beauchamp and C. K. Yuen

Digital Methods for Signal Analysis is concerned solely with digital techniques in signal analysis. The book is a wholly reworked and new edition of *Signal Processing, Using Analog and Digital Techniques* (1973), which takes full account of changes since then, particularly in the areas of special-purpose data acquisition design and on-line processing systems.

The book is written primarily for people who are studying information which can be expressed as a signal, and who need to analyse the signal to produce results that are useful to their work. To this end, the authors strike a balance between theory and practice. Without requiring advanced mathematics or probability theory, they introduce the reader to the basic theoretical concepts of signal processing and demonstrate their relevance to the selection, design and analysis of computation procedures.

Dr K. G. Beauchamp is Director of Computer services at the University of Lancaster. He has been concerned with signal processing for a number of years at Cranfield Institute of Technology and the Atomic Weapons Research Establishment. Dr Y. C. Yuen is a Senior Lecturer in Information Science at the University of Tasmania.

Circle No. 15 on Reader Enquiry Card.

Observatory . . . trekking through the California high desert" and even "flying low over a Minnesota lake on the trail of timber wolves". The full weight of "the largest and most experienced staff of science reporters of any newspaper in the country" has produced journalism that is poorly researched and badly written. Surely the US national newspaper of record can produce better.

A collection by Isaac Asimov (*Life and Time;* Doubleday: New York; $9.95) is, in its own way, not much different. In place of nine reporters we have the Asimov factory — 198 books in 20 years. Asimov is a clear writer, now victimised by his own success. His *Fantasy and Science Fiction* essays are issued in book form "every 17 months", he writes for an amazing range of magazines from *TV Guide* to *Penthouse*; and he is on call to editors all over the country for articles on topics as diverse as special relativity, taxonomy, world government and space law. He is now a writer who tells his "Gentle Readers" that "my cheerful self-satisfaction is no evidence in itself that everything I write is routinely accepted". (An article on memory was rejected by *Playboy*.)

This collection, which includes cast-offs, previously unpublished works, out of print essays and duplicated material expresses little more than Asimov's "relentless determination to see that everything I have written (within reasonable limits) receives the relative permanence of book publication". Asimov has had little criticism of his work in his long career — and it shows. "I write as much as ever and the material I turn out seems to be as good as ever; not in my opinion only, but in those of my editors and readers who have no reason to lie to me".

Asimov has managed to avoid the errors of the daily journalists; he is thorough and generally accurate in reporting the facts. But his attitudes and opinions are superficial and anachronistic. There is a reflexive and unthinking defence of genetic engineering, a male chauvinist defence of the use of the word "man" in place of human, a superficial technocratic account of world politics and a nationally chauvinistic advocacy of space colonisation to be "carried through as wisely and as farsightedly as the colonisation of the American West". The Asimov of the negative solubility hoax has disappeared and he now writes as a pompous elder statesman out of touch with changing world conditions — from the job crisis in science to the emergence of revolutionary Third World political movements. His success is a success of the early 1960s and he shows little inclination to change his formula.

Joe Schwartz

Joe Schwartz is on leave from the City University of New York.

Affection for birds

BIRDS give more pleasure to humans than any other class of creature, their own kind excepted. This pleasure takes many forms and finds expression in ways which not infrequently conflict. Many who delight in birds which visit their gardens deplore those who enjoy birds caged, who in turn despise the wildfowler, who deprecates the egg-collector, who dislikes the conservationist. Thus, each forgets that he is united to the other by a bond of common interest — affection, however expressed, for birds — and that sometimes one is in another's debt.

It is an intriguing irony that the conservation of Britain's most significant contribution to the world's avifauna is entirely dependent on a section of the shooting fraternity. The red grouse — a distinctive subspecies of the willow grouse — is found only in the British Isles and would be far less numerous than it is today were it not for shooting, while the moors where it lives would be sheepwalk or sitka spruce and biologically much less interesting. In *Going to the Moors* (John Murray: London; £11). Ronald Eden traces the social history of grouse-shooting and tells something of the development of moor management and shooting techniques. In the eighteenth century, the shooting of upland game was a rugged and expensive affair — a rich man's expedition which, though the support staff might bring up supplies of cheese, sherbets and champagne, was nonetheless a serious operation. Then the romantic poets began to work their influence on good taste, which had long eschewed wild landscapes; Albert and Victoria set the seal of approval on the Highlands and suddenly the numbers of those travelling north became a multitude. In response, traders and entrepreneurs were quick to smooth the way and line their pockets. By the latter half of the nineteenth century the grouse season was part of the social calendar. Grouse management slowly became a science, designed to produce the maximum number of birds for the guns. But the grouse ceased to be a bird, a thing of beauty with a biology and behaviour of considerable intrinsic interest: for most of those involved it became a symbol and an excuse for quite unrelated pleasures: even those who actually saw and shot the birds were preoccupied with bags and performance. The book is copiously illustrated in black and white and entertainingly written to appeal to those who are or would like to be part of the grouse season society.

It is a far cry from the organised and luxurious pursuit of grouse to the unpredictable and often uncomfortable pursuit of greenshank. Desmond Nethersole-Thompson's dedicated and untiring study of this uncommon and elusive species began in 1932. With his wife, he describes in *Greenshanks* (T. & A.D. Poyser: Berkhamsted, UK; £8.80) not only their findings on the biology and ecology of the birds but also the trials and rewards that have been part of the experience. Greenshanks breed in the most lonely and desolate parts of Britain — places like the flows of Sutherland which not a few naturalists dismiss as "Mamba" — miles and miles of nothing at all. But to the Nethersole-Thompsons it is clearly a place of enduring fascination. The wildness and the wetness of this still almost immaculate wilderness are for them not the least of its charms and one must admire the cheerful acceptance of storm-bound days huddled in sleeping bags, thus saving food and fuel, until the weather improves enough to permit a return to field work. Greenshank nests are notoriously difficult to find and were once the "Cordon Bleu" of the egger: in describing the problems of nest-finding, the book conveys much of the author's own enthusiasm, and throughout there is a pleasant and rare mix of thorough scientific analysis with abiding affection for the subject. Though centred on the authors' own findings in Scotland, the book draws together other sources in Britain and Europe to form a comprehensive appraisal of current knowledge. Occasionally, the casual reader

Walking-up Grouse, by Edward Neale, 1893

Taken from *Going to the Moors*

will wish to skip minutiae but it is no disadvantage that they are included for the specialist.

Rarity and the challenge it represents appeal to many naturalists and thus they may overlook opportunities for research and enjoyment on their own doorsteps. The town pigeon lives a life of dependence on man, treating his buildings like the cliffs inhabited by its wild progenitor the rock dove and treating man himself like the cattle or goats amongst which rock doves walk unconcerned. In *The Public Life of the Street Pigeon* (Hutchinson: London; £6.95), Eric Simms takes a comprehensive look at a bird which has lived with man for well over 6,000 years. The first part of his book looks at the general biology and relationships of the order, and at the pigeon's past and present relationships with man, who pets it, eats it, races it, breeds it into bizarre forms, uses it in war and wages urban war against it, experiments with it or on it, and is photographed with it standing on his head. While grouse shooting has the social cachet and is today a not insignificant earner of foreign currency, pigeon racing outstrips it on several counts with, at Simms' estimate, several million birds kept by 100,000 pigeon fanciers and exceptional individual birds changing hands for several thousand pounds. One thing might unite these interests — a common dislike of that impartial predator the peregrine falcon. In fact, it was the pigeon racer's outcry that encouraged British conservation bodies to look at peregrine populations 20 years ago and thus discover that they were declining because of an unrecognised group of environmental pollutants, the organochlorines. The second half of the book is devoted to the street pigeon at home, its biology and behaviour, revealing how much of value and importance can be learned from the commonplace. The book contains much information, presented in succinct and entertaining style and generously illustrated in black and white.

Man's relationship with parrots is also one of some antiquity but founded on different emotions. Pigeons lack the anatomy to swagger or swear. Parrots do not provide us with a source of fresh meat in winter. The modern pigeon fancier is much preoccupied with successful breeding but the parrot keeper apparently sees his bird more as an ornament than an organism, making little attempt to provide conditions under which the birds can behave reasonably naturally, let alone breed. *Lovebirds and Related Parrots* by G.A. Smith (Paul Elek: London; £15) necessarily reflects this attitude as well as reminding us of how little is known about birds which do not occur in Europe or North America. Thus, the section on ethology occupies four pages compared with that on "simple genetics, colour mutations and colour definition" which runs to thirteen, plus an apology for compressing the subject into so small a compass. The bulk of the text summarises the pitifully little that is known of individual species in the wild. To give fair credit, the author places great emphasis on captive breeding — aviculture can no longer regard wild populations as an inexhaustible source of supply: its own depredations have had severe effects on rarer species and many others have suffered greatly from recent habitat changes. By drawing attention to problems and partial solution, the book could be a valuable contribution to the conservation of parrots.

Though scientific ornithology has only lately begun to discover much of birds' basic biology and behaviour, they were not unnoticed by previous generations, whose dialect names can provide useful insight into the earlier distribution and abundance of species. *All the Birds of the Air* by Francesca Greenoak (André Deutsch: London; £6.95) collates many, but not all, the British names. Some one suspects of being Victorian contrivances and there are some mis-attributions. The author gives a very personal view of each bird's place in lore and literature, making a pleasant if sometimes inaccurate read for the sentimental bird lover.

Christopher Perrins combines accuracy with readability in *British Tits* (Collins: London; £6.50). In the best New Naturalist tradition, the author covers the seven species of British tit, drawing together all available material from sources throughout their world range but in particular from Holland, where studies have gone on almost without a break since 1912, constituting one of the largest series existing for any bird anywhere in the world. In Britain, intensive study at a site near Oxford began in 1947 and has continued since, providing not only a direct opportunity for observation but also a comparison between the British and Continental subspecies living in subtly different woodlands. Tits are apparently a highly intelligent order, having mental and manipulative skills evolved for the survival of invertebrate eaters in a cold climate. As such, they are of particular interest in behavioural studies. The book commences with a chapter summarising the biology of each species and then goes on to examine them as a group, comparing ecological differences, food requirement, feeding habits, breeding, population dynamics and the relationship between tits, their prey and predators, respectively. The illustrations are apposite and there is an exhaustive bibliography and index. Perrins' style is eminently readable: a mass of complex information is organised with an unobtrusive precision that belies the meticulous care necessary in such work. Nor is he afraid to develop into the field of stimulating speculation an argument based on observed fact. There are still all too few such studies.

Birdwatching guides

NEW bird books keep coming on the market at such a rate that it is difficult to keep up with them or to know whch ones are worth having. This review covers six smallish books which have been published in the past twelve months or so, mostly very recently. As will be seen, the books are quite disparate in their aims, so much so that comparisons between most of them are not profitable: the choice will be governed by the reader's requirements.

A Field Guide to the Seabirds of Britain and the World by G. Tuck and H. Heinzel (Collins: London; £5.25) is the most specialised of the works discussed here. This is a "standard" type of field guide, with a coloured picture, often showing more than one age group or plumage, of each species together with a descriptive text and a distribution map. The text concentrates almost entirely on identification/plumage and range. However, short sections at the beginning of each family or group amplify this with descriptions of behaviour and nesting habits. The text also contains a large number of line drawings, some of them adding additional identification features.

As already mentioned, this is a book for the *afficionado* or the globe-trotter. Although it covers almost 300 species of seabird, only a couple of dozen of them breed in the United Kingdom and several of these are rare. This edition has an extra 24-page section at the back describing British birds in greater detail with larger distribution maps for the British Isles only; apparently there will be later editions in which the resident birds of other areas of the world will be covered in greater detail.

It is a difficult task to attempt but, although it is not without its faults, it has on the whole succeeded. Both plates and text will be valuable for bird-watchers; and in ecological terms it certainly fills an empty niche. My main comment to the user would be a word of caution. The text describes differences (for example, between the shearwaters) giving the impression that the species concerned can be reliably separated in the field. Some of the characters given, such as leg colour, can be virtually impossible to see unless the bird is in the hand. In areas where numbers of closely related species occur, it takes a very experienced fieldworker to identify the birds with any degree of reliability.

Wetlands — estuaries, marshes or even reservoirs — are often rich in birds. Malcolm Ogilvie's book *The Birdwatcher's Guide to the Wetlands of Britain* (Batsford: London; £4.50) describes the main wetlands of England, Wales or Scotland (but not Northern Ireland), how to get there and what one is likely to see there. The text concentrates on the better areas in each county and on the wildfowl and waders. These two groups of birds are often present in impressive, even spectacular numbers, and in recent years, because pressures on land use have led to many 'development' plans for such 'waste' ground, ornithologists have been counting the birds on these areas. Doubtless partly because of our relatively mild winters, they have found that our wetlands harbour enormous numbers of wildfowl and waders. Birds from other areas of Europe and from the Arctic visit us in great numbers. In mid-winter British wetlands may play host to very large proportions of the populations of these birds; and therefore the conservation of our wetlands is of pressing urgency.

The book is divided by county and each major water is briefly described with information on how it might be reached. There follows a list of the most important species of wildfowl and waders together with the range of numbers which may be expected. Although more detailed figures are available to the specialist, for the casual reader these are the only figures readily available. Other species of special interest in each area are mentioned very briefly; I would have welcomed a slight expansion of this section. The book will be useful, especially to those who like to travel some distance for their birdwatching.

Peter Conder's *RSBP Guide to Birdwatching* (Hamlyn: London and New York; £2.50) is a useful little book and good value for its price. I found the title not wholly descriptive of the work. The early part is indeed a useful initiation to birdwatching, covering books, binoculars, places to go, how to keep records, and so on. However, almost two-thirds of the book comes closer, to my mind, to bird study. It covers aspects such as counting birds (usually not as easy as it may seem at first sight!), the lives of birds (flight, feathers, moult, bill, legs, and so on), migration and ringing, territory and song, nesting, distribution, habitats, ecology and food. In each of these sections the subject matter is described simply and clearly, and the ways in which the reader might make his or her own observations are suggested. There is a final section on conservation and protection, and there are useful appendices on books and other literature of ornithological societies. Useful for the beginner.

The Birdhouse Book by D. McNeil (Pacific Search Press: Seattle, Washington; paperback $8.95) contains useful sets of instructions on how to build nest-boxes and bird-feeders of a wide variety of designs. Beware, however, if you fancy the design of a nestbox, that the bird for which it is designed breeds in Britain, as the book was written for the American market. Although this is a well-illustrated book with clear construction plans, a better work for European readers is the booklet *Nestboxes* published by the British Trust for Ornithology (Tring, Herts, UK).

Circle No. 24 on Reader Enquiry Card.

(Whizzard Press/André Deutsch: London; £4.95) is, as its name suggests, an introduction to bird-watching. It introduces the subject with sections on note-taking, how to identify birds, and so on. It then goes on to take the reader to seven selected bird-watching areas, such as the Isles of Scilly and the Cairngorms. For each, it describes the area fully and then the kinds of birds that one might see there. It is an attractive narrative without going into too much depth. The aim is to describe the typical birds of different areas rather than all the birds in Britain. It is lavishly illustrated by the author's pleasing line drawings and coloured sketches. In addition there are many photographs by Philip Sayer; the black-and-white ones do not always seem to have reproduced well, but the coloured photographs of the habitats are, as a group, among the best I have seen anywhere.

Alan Richards' *British Birds: A Field Guide* (David and Charles: Newton Abbot, UK; £4.95) is a departure from the standard field guide which illustrates each species with small coloured sketches designed to show the key field characters. Many current field-guides include the birds from a very large area; the British beginner must therefore sort through large numbers of species which are unlikely to occur. This book concentrates on British breeding species plus the regular winter visitors. On the whole the selection seems pretty good, though a few birds likely to be seen by the beginner get only a brief mention (for example, Bar-tailed Godwit, Great Skua, Firecrest, Rock Pipit). In this book there are two illustrations for each species, a line drawing and a coloured photograph. The text amplifies the pictures for the description and carries extra information on voice, habitat, nest and status. On the whole, this is a successful work and will be a useful addition to the beginner's library. The photographs are usually adequate for identification, but I wish fewer of them were taken at the nest, as this does not always give the right 'jizz'. For example, the waders are usually seen in other habitats where they look quite different. Also, at times, the bill shape is obscured by a beakful of insects. Apart from this, they are a pleasing collection of photographs and the general production is attractive.

Pretty birdies

The series of books of paintings and photographs reviewed here reflects again the publishers' interest in the market provided by the ever-growing number of those attracted by birds: in the last four years over 100,000 people have joined the RSPB, bringing its total membership to over 300,000. Sadly, the contents of books published for this market are often of poor quality: either the paintings or photographs are hardly worth publishing — or buying — or else the text is ordinary, repeating *ad nauseam* the description of birds and their behaviour that can be found in the usual textbooks. Sad it is, too, that few authors whose books are reviewed here have tried to match the artist or photographer with original or more personal observations.

An example of this discrepancy is Illustrated by the *Country Life Book of Birds of Prey* (Country Life Books/Hamlyn: London; £20). Gareth Parry, a young Welsh artist still in his twenties, is a meticulous draughtsman who paints almost every barbule and barbicel. But he has not mastered the art of perspective and some birds look flat: a young kestrel really has got its underparts in a twist. Parry also falls into the habit of portraying breaks in the feather vanes, presumably to give a verisimilitude to the picture which is in fact artificial. In spite of these criticisms, however, Parry is a promising artist of the barbicel school of painting. Photographic as his pictures often are — and I am not implying that they are copied — they capture the atmosphere of the bird and its habitat; the winter paintings of the gyrfalcon on an estuary and the white-tailed sea-eagle made me shiver. The book covers all British diurnal and nocturnal birds of prey, but the vignettes by other artists seem out of place. The text by Rory Putnam is competent but it contains nothing original. The book is worth looking at but at £20 I wonder if we are not paying for the name of the publisher.

T. Lambert and A. Mitchell's *Birds of Shore and Estuary* (Collins: London; £6.95) is another coffee-table book produced for popular appeal, with just over 50 paintings of a range of sea and shore birds. Like Gareth Parry he paints in great detail but not so accurately. The colouring of the feathers, as well as the shapes of some of the birds, is so unreal as to make identification a puzzle, and it is difficult to see how some of the birds depicted flying could get their wings into the positions the artist has contrived for them. Alan Mitchell writes a short essay introducing the four groups of paintings: gulls, terns and skuas; breeding birds; ducks and geese; and finally, birds of estuaries. Each picture is accompanied by a short, popular commentary of about 300 words.

A contrast to these books is found in Réna Fennessy and Leslie Brown's *Birds of the African Waterside* (Collins: London; £12), although it is another large book of 24 paintings depicting 30 species. The paintings are warm, as befits a book on African birds. Her painting is less representational than that of Parry and Lambert and is generally very successful, although the white-starred bush robin has a badly tailored skin with wrinkles down its back — another painter's cliché which may fool the unwary. The remaining paintings are attractive studies of the waterbirds most likely to be seen on the edges of African lakes and rivers. The text is further decorated with sketches of birds and habitats. Sadly, two plates are transposed: those of the collared pratincole and the three-banded plover.

As one would expect from Leslie Brown, the text has original touches: the introduction is an account of the author's safaris up and down rivers and lakes rather than an essay on the different types of wetland, although as Leslie Brown has wandered over great sections of Africa he arrives at a good summary anyway. The text accompanying each of the plates contains more original observations and anecdotes than one usually finds in a book of this sort.

The late C.F. Tunnicliffe's *Sketchbook of Birds* (Gollancz: London; £7.95), introduced briefly by Ian Niall, is by far the most worthwhile of the books of paintings I have been reviewing. It is made up of 132 colour reproductions of pages from his early sketchbooks dating from the early 1930's to the early 1950's. The sketches are arranged in five groups: sea birds; waders; geese, ducks and swans; birds of prey; and finally miscellaneous birds. They are of value to the serious ornithologist and bird artist and will give lasting enjoyment to all who, in one way or another, are intrigued by birds. Often detailed, the feather by feather drawings, from which the later paintings were made, show changes in plumage from season to season, different feeding methods, a range of typical postures — relaxed, wing stretching and so on. Others are studies for future pictures in water colour or in crayon. On some of the plates Tunnicliffe's own descriptive notes appear. Legends give details of identification, place and date of drawing. These sketches confirm him as an outstanding artist, arguably one of the greatest bird painters of all time, ranking with or above Bewick, Audubon, Liliefors. Since the present group of sketches was taken from the earliest sketch books I would hope to see more of his later sketches. Finally, as well as being the best book in this group it is also the least expensive.

Eric Hosking's Birds (Pelham: London; £10.50; published as *A Passion for Birds* by Coward, McCann and Geoghegan: New York; $25) is an excellent title for a selection of photographs by the grand master of his profession. What Tunnicliffe was to bird painting Eric Hosking is to bird photography and, like Tunnicliffe, his photographs have stimulated the growth of interest in birds. The book consists of some 200 photographs, many of them classics, of which 80 are in full colour. It is often the reproduction of the photographs which has let this book down: some of the photographs have been cropped and enlarged to the extent that definition is poor and the rendering of the colour photographs rather pale. Eric Hosking and Kevin MacDonnel have contributed a short text in 13 chapters, a mixture of rather elementary nature notes and interesting photographic information. It is a pity that Eric Hosking did not write more about his photographic experiences. Finally, full photographic details of each photograph are given in the appendix. In spite of these criticisms it is still a very worthwhile book, with many photographs which are not only beautiful to look at but from which it is also possible to learn.

The bird photographs of Frederick Kent Truslow, a photographer well known in the US, have been treated rather differently. In *The Nesting Season* (Studio Books/ Viking: New York; $25; Elm Tree Books/ Hamish Hamilton: London; £15), the photographs are arranged in the sequence of the breeding cycle. The first half of the book, which is dominated by a popular but well written account of the nesting season by Helen D. Cruickshank, is illustrated by black and white photographs, of which few occupy more than a quarter of the page, thus giving the text more prominence than is usual in a book of this kind. The photographs lose nothing; they are all pin-sharp and seem much better printed the in *Eric Hosking's Birds.*

The second half of the 136-page book is entirely composed of colour plates, most of which are excellent but others have been over-enlarged, depicting the bird at least twice life-size, resulting a poor definition and colour reproduction. In those where the picture is given a two-page spread the middle portion of the bird is lost in the binding. Some photographs are superb, particularly the blue heron, mutual preening of moorhens unfortunately labelled "battle for dominance", and the American national bird — the bald eagle — has a striking portrait. Unique are three photographs showing a pileated woodpecker carrying its three eggs to a new site after the top of the nest tree had broken off, exposing the nest. An appendix gives some of the photographic data but lacks details of film stock and camera.

The five volumes published by Orbis entitled *Birds of Ocean and Estuary, Birds of Mountain and Moorland, Birds of Marsh and Shore, Birds of Heath and Woodland* and *Birds of Hedgerow and Garden* (Orbis: London; £7.50 each) have made two previous appearances in Europe as a part-work, first in Italy and then in Britain under the title *The Orbis Encyclopaedia of Birds of Britain and Europe.* In Italy it was nothing more than an encyclopaedia of European birds, describing 642 species in systematic order with poor paintings of birds — nearly all the beaks, for instance, were too small, the colours were not always representative and often the shapes are inaccurate. For the English part-work John Gooders made the best of a bad job and wrote a number of popular essays on various aspects of a bird's life, added many excellent photographs and, particularly useful, colour plates of the wing patterns of nearly every group of birds. This third version is the same English part-work now in five hard-backed volumes with the misleading titles given above. The titles are misleading because as the cover admits in small print, the work lists the birds in systematic order. Consequently, the first volume, entitled *Birds of Ocean and Shore,* includes most ocean or shore birds but omits waders, passerines and so on which regularly visit the shore. The same criticism can be made of the other volumes. *Caveat emptor* applies and the £37.50 for the five volumes might be better spent elsewhere.

Peter Conder

Peter Conder is a writer and a wildlife management consultant who has recently been working for IUCN/WWF in Pakistan and Jordan.

Blackie

Invertebrate Neuropharmacology

Lucy D Leake
Robert J Walker

The invertebrates, with their less complicated nervous systems, are being increasingly used to model the neuronal activity of vertebrates. In reviewing progress in the field to date, the authors of this book highlight the benefits and shortcomings of the applications of invertebrate studies to the vertebrates, and indicate possible future developments. A comprehensive, current bibliography is an important feature of the book.

This will prove an important source book in a developing area for researchers in pharmacology.

Wildlife in danger

THE conservation band-wagon trundles on, dropping a seemingly endless shower of new books about endangered species and their approaching extinction. One may wonder how many hundred square miles of virgin forest are clear-felled every year to make pulp for the paper on which they are printed, and what happens to the inhabitants, plant and animal, of the biome destroyed. Some of the books are worth the sacrifice, but as for others — less talk might result in more conservation though fewer royalties for the riders on the wagon.

Australian Endangered Species (Cassell: London; £15) by Professor Derrick Ovington, formerly Professor of Forestry at Canberra and now Director of the Australian National Parks and Wildlife Service, is one of the best books on the problems of the conservation of nature to have appeared for a long time. Although it deals specifically with the fauna of Australia, much of its information is applicable to any part of the world. The author writes as a scientist and deals with his subject objectively without sensationalism, and the resulting clear and sympathetic account of the history, present state and future prospects of the Continent's fauna and flora makes fascinating reading. The early white pioneers, isolated in an alien world and facing incredible hardships, understandably felt an overwhelming urge to subdue and transform the wilderness in order to survive. Many species of the fauna were abundant and were killed for food or recreation, or, when farming was established, as vermin. The early settlers did not understand that breaking-in the wilderness for agriculture or stock-raising so altered the environment that some native species could not survive. Furthermore they could not foresee the dire results of the well-meant introduction of alien species for practical or sentimental reasons. The extinction or extreme rarity of many species is attributed in frequent instances to habitat alteration by stock or rabbits, and to introduced predators such as the cat and the fox, so that species once widespread and abundant have suddenly become scarce or disappeared. "Like fresh water or clean air, wildlife is liable to be taken for granted and its value underestimated until supplies run short".

The heart of the book deals with the 23 Australian mammal, 18 bird, and 2 reptile species that are regarded as endangered. Each species is depicted in a full-page coloured illustration facing a page with its description and biological details, and a map of former and present distribution; the pictures are beautifully done and well printed. The book concludes with an account of what has been done, and what remains to be done, in conserving Australian wildlife, emphasising the need for massive further research and for education: "the dissemination of information about wildlife to many people and agencies is essential if sympathy with wildlife protection measures is to be translated into active support and adequate funds are to be made available." This is a splendid book that will be valued by specialist and layman alike.

The Living Swamp (Orbis: London; £5.95), by A. Borgioli and G. Cappelli, describes the different kinds of marshes, swamps, fens and bogs that occur throughout the world, and illustrates their flora and fauna with many excellent colour photographs, all of them beautiful and many dramatic. The first of the four chapters deals with the aquatic environment and explains the origin and evolution of marshland, pointing out its inherent instability under the influence of natural forces as well as under the activities of man. Many are threatened with destruction through efforts to reclaim wastelands for agriculture or other purposes, such as the construction of airports for commerce or marinas for amusement. The second chapter displays the "marsh microcosm" and the food chain, ranging upwards from unicellular algae to vertebrate animals, based on the rich primary production of organic material synthesised by plants. The illustrations of this chapter include many unusual photographs of invertebrates, mainly insects, and excellent pictures of amphibians and reptiles. A well illustrated chapter on birds, "the lords of the marsh", then follows, pointing out how few mammal species compared with the host of birds are able to take advantage of this environment. The final chapter describes the characteristics of the major marshlands of the world and lists them by countries, noting the national parks and reserves where conservation of this specialised habitat is practised. The text well matches the illustrations to make the volume more than merely a coffee-table book; it has, however, suffered here and there in translation from the Italian, particularly with names of species, as where it mentions "greylag" geese in Argentina.

White-fronted lemur, San Diego Zoo

Taken from *Lifeboats to Ararat*

In 1903 certain sportsmen, fearing that the stocks of big game that they hunted were diminishing, founded a Society for the Preservation of the Wild Fauna of the Empire, with the object of establishing game reserves and preventing the natives poaching the animals the alien whites wished to kill; no wonder the popular press lampooned them as "penitent butchers". Mr Richard Fitter has adopted the nickname as the title for his short history of the society (*The Penitent Butchers: 75 Years of Wildlife Conservation*; Collins/Fauna Preservation Society); Sir Peter Scott has done the drawings. Wildlife protection has always begun as an attempt to preserve game animals from overshooting or overhunting: "one of the few amenities that could be offered to soldiers (officers only, of course) and administrators marooned in darkest Africa . . . was shooting big game." The move from the protection of game to the protection of all wildlife came slowly, and it was not until well after 1945 that the conservation of whole ecosystems gained acceptance. The author devotes a chapter to breeding rare animals in captivity in order to return stocks to the wild, a measure that has had several successes, but is a last desperate remedy that for many reasons cannot hope to be repeated often.

The difficulties of breeding rare animals in captivity to save them from extinction are discussed in some detail by Sheldon Campbell in *Lifeboats to Ararat* (Weidenfeld and Nicolson: London; £6.50). This book, by a former zoo-keeper, is a chatty anecdotal account of life "behind the scenes" in zoos round the world and particularly in the San Diego zoo of California. The author says, "no activity by zoos has received more lip service and been less seriously undertaken than captive breeding. All zoos subscribe to the idea, but few are really doing much about it." A major obstacle to success in returning captive-bred animals to the wild is the difficulty of gettting them to earn their living when they have known only the soft life of a zoo "welfare state". The difficulties are such that the author concludes: "the probability is that zoos will hold many captive-bred species far into the foreseeable future, and, possibly, some for ever."

The truth of this statement is well illustrated by Peter H. Beard in *The End of the Game: The Last Word from Paradise* (Collins: London; £10), an unusual but interesting and instructive book. It is the story of the elephants of the Tsavo region of Kenya, teeming with wild animals at the beginning of the century, but which, after being made a National Park, degenerated into an empty desert strewn with dead trees and the skeletons of the elephants it was intended to preserve. When the wardens and rangers of Voi Force finally stamped out poaching in the Tsavo Park in the 1950s they unwittingly sealed the fate of Tsavo,

Plasma Proteins

edited by **B. Blombäck**, *Institution for Coagulation Research, Karolinska Institute, Stockholm,*
and **L.A. Hanson**, *Department of Immunology, Institution for Medical Microbiology, University of Gothenburg, Sweden*
Coordinating editor: **H. Winberg**, *AB KABI, Stockholm, Sweden*

This book provides a survey of the developments in the field of the chemistry of the plasma proteins. The biochemistry, physiology and clinical aspects of the more important proteins are discussed in special chapters. A detailed and up-to-date section at the end of the book is devoted to laboratory diagnosis in connection with the plasma proteins. The various methods which are available are described together with their value and usefulness in diagnosis and clinical application.

October 1979 — 420 pages
0471 99730 7 — $62.00/£22.50

Human Plasma Proteins:
Their Investigation in Pathological Conditions

by **J.W. Keyser**, *Department of Medical Biochemistry, The Welsh National School of Medicine, The Royal Infirmary, Cardiff*

This book discusses plasma protein changes found in disease and after injury. There are also chapters on cerebrospinal fluid proteins in neurological diseases and urinary proteins in renal diseases. Significant fundamental research on special topics such as the mechanism of the post-trauma 'acute-phase' protein response is described, but emphasis is on the practical value of protein measurements in diagnosis and in the management of patients. Appendixes describe selected practical methods of protein analysis.

November 1979 — 330 pages
0471 27598 0 — $50.00/£18.50

Flow Cytometry and Sorting

edited by **M.R. Melamed**, *Memorial Sloan-Kettering Cancer Center, New York,*
M.L. Mendelsohn, *University of California, Livermore*
and **P.F. Mullaney**, *Los Alamos Scientific Laboratory, New Mexico*

An important new book covering the wide scope of present applications and future possibilities in the new and rapidly growing field of flow cytometry. It discusses all the theoretical and practical aspects of instrumentation, methods of cell preparation and staining, precise quantitation of cellular DNA, nuclear chromatic structure analysis, cell sorting, automated karyotyping, cell cycle kinetics, and a comparison and description of available commercial instrument systems.

November 1979 — 734 pages
0471 02078 8 — $85.00/£39.50

Liver and Biliary Tract Disease in Children

by **D. Alagille**, *Hôpital d'Enfants de Bicetre, Université de Paris (Paris-Sud) and INSERM*
and **M. Odievre**, *Université de Paris (Paris-Sud);*
translated by **Micheline Sainte-Marie**

Based on the authors' distinguished experience in the investigation of hepatic disorders in childhood, this volume serves as a cornerstone for paediatric hepatology, detailing disorders both common and rare.

October 1979 — 376 pages
0471 05256 6 — $50.00/£23.00
Not available from Wiley Ltd. in France, Belgium or Switzerland

Basic Physics in Diagnostic Ultrasound

by **J.L. Rose**, *Drexel University, Philadelphia,*
and **B.B. Goldberg**, *Thomas Jefferson University Hospital*

An introduction to principles of the basic physics necessary for understanding diagnostic ultrasound. The coverage also extends to fundamentals of related disciplines, including mechanics, electronics, and mathematics, and their application to ultrasonics.

November 1979 — 356 pages
0471 05735 5 — $33.50/£15.50

Radiation Shielding and Dosimetry

by **A.E. Profio**, *University of California, Santa Barbara*

An up-to-date reference and text that discusses the design of shields for radioactive sources, X-ray machines, low energy accelerators, and nuclear reactors. It introduces dosimetry in industry and medicine, examining the predition and measurement of dose in the body from external and internal sources, and the biological effects of ionization radiation.

Nephrology

edited by **J. Hamburger, J. Crosnier** and **J.-P. Grunfeld**, *all of the Hôpital Necker, Paris*

This up-to-date and comprehensive single source of information on nephrology combines the expertise of ninety-two world-renowned specialists in the field. It presents in-depth discussions of all relevant topics, from basic data to detailed and practical descriptions of techniques used in nephrology. The latest pathological entities and improved techniques are featured along with a background of immunology and genetics.

A Guide to a Regional Dissection and Study of the Human Body 4th Edition

by **R.C. Crafts** and **R.T. Binhammer**, *both of the University of Cincinnati College of Medicine*

A working guide for the dissection of the human body, with step-by-step procedures for actual dissection and observation. Organized by region, it is designed to be used in conjunction with Craft's *A Textbook of Human Anatomy*. Pertinent questions are interspersed throughout, and a sufficient amount of writing space is provided.

NEW GEO BOOKS FOR OUR TIMES

Fundamentals of Reservoir Engineering

by L. P. DAKE

(Developments in Petroleum Science, 8)

TEXT BOOK

"There have been few books published covering Reservoir Engineering since the classic by Craft and Hawkins 'Applied Petroleum Reservoir Engineering' which has been the standard text in the industry since 1959. This book by L. P. Dake may well take its place. It gives a clear up-to-date account of the basics of Reservoir Engineering, starting with the essential physics and leading on to the theory and practice of oil and gas well testing, pressure analysis methods and finally water influx and fluid displacement techniques. The text is clear and is well illustrated by worked examples. Our students have found it most useful."

- Dr. R. A. Dawe, Lecturer in Petroleum Engineering at the Imperial College of Science & Technology, London

1978 2nd repr. 1979 xvi + 444 pages
US $29.25/Dfl. 60.00 Paperback ISBN 0-444-41830-X

Ground Freezing

edited by H. L. JESSBERGER

(Developments in Geotechnical Engineering, 26)

Contains the proceedings of the First International Symposium on Ground Freezing held in Bochum in March 1978. The application of the ground freezing technique in geotechnical engineering has increased rapidly throughout the world in recent years and this symposium provided international scientists with the opportunity of exchanging information about engineering with frozen soils and related frost research problems.

Elastic Waves in the Earth

by WALTER L. PILANT

(Developments in Solid Earth Geophysics, 11)

Based on a one-year course taught to graduate students at the University of Pittsburgh, here is an advanced textbook on theoretical seismology which provides a complete and up-to-date account of elastic wave propagation.

1979 xii + 494 pages US $48.75/Dfl. 100.00

Geosounding Principles, 1

Resistivity Sounding Measurements
by OTTO KOEFOED

(Methods in Geochemistry and Geophysics, 14A)

During the past decade, tremendously important innovations have been made in the methods of interpreting resistivity sounding data, and the advent of smaller, cheaper computers and calculators has made accurate interpretation possible at a reasonably low cost. This book is the first to incorporate all these developments and it will be invaluable both to researchers and to those who apply the resistivity sounding method in practice.

Climates Throughout Geologic Time

by L. A. FRAKES

The first modern book on paleoclimates, this is a concise, integrated history of the climatic conditions of the Earth throughout all geologic time. Its broad scope and the integrated approach to the subject makes this work of great value to all those involved in paleoclimatology.

1979 xii + 310 pages US $58.50/Dfl. 120.00

Karen Blixen and Ingrid Lindstrom, Ngong, 1921

Taken from *The End of the Game*

for the elephants multiplied, and when the great drought came they destroyed their habitat and perished in the wilderness they had made. The book is lavishly illustrated with photographs of animals and men from the early days of colonial settlement until the present, a fascinating collection. The coming of the white man who built a railway and imposed his will on the land and its inhabitants was "attended by glory and courage, ennobled by sacrifice, enriched by science, medicine and law. But it marked the beginning of the end in a land where nature herself had always been sovereign . . . It is too late to undo what has been done . . . we have conquered nothing at all."

L. Harrison Matthews

L. Harrision Matthews was formerly Scientific Director of the Zoological Society of London, and a member of the scientific staff of the Discovery Expedition, 1924-28. He has also done zoological research in the Arctic, South America, and Africa.

Making a living

THE word 'predator' immediately conjures up visions of a lion tearing at a carcass or of a peregrine falcon swooping on to its prey, but smaller and more numerous predators are at work everywhere if only we look for them. There is all the drama of the predator and its prey when a wasp butchers a butterfly or when a dragonfly pursues its insect victim over a garden pond. *The Hunters* (Hamlyn: London and New York; £5.95) by Philip Whitfield takes an imaginative and exciting new look at the world of predators and will inspire student and layman alike. It covers the whole range of hunters from tiny single-celled protozoa to large mammalian species. There is an introduction on population numbers and food chains and then a series of chapters that group predators together under the methods they use for hunting.

Tigers, praying mantis and chameleons all hunt by stealth, relying on concealment to enable them to get close to their quarry. Some animals hunt in groups like soldier ants, pelicans and hunting dogs. Others, such as burying beetles and vultures, scavenge for dead animals. Ciliate protozoa, flamingos and baleen whales all use filtering mechanisms to catch their aquatic prey. There are also chapters on predators that use tools or traps and those that are specialised in the food they eat or in their methods of detecting prey. Every predator is given a double-page spread of text and diagrams which explain its hunting method; and the book is illustrated with some superb drawings by Richard Orr and Michael Woods. These include a walrus disembowelling a narwhal, an anemone engulfing a fish, a boa constrictor crushing an ocelot and a brown bear sweeping a salmon out of a torrent.

These two artists have produced some more beautiful and informative diagrams and drawings for another book in the same series, *The Animal Family* (Hamlyn: London and New York; £5.95) edited by Philip Whitfield. This looks at the diverse ways in which animals find mates and rear their young. Like the previous book, it illustrates various topics with reference to examples chosen from the whole Animal Kingdom. The mechanics of sexual reproduction are explained, including the structure and function of the reproductive organs, hormones, fertilisation, and the strange animals that change sex. There are clear diagrams illustrating the variety of visual and vocal courtship displays, territorial behaviour and nest sites. Some examples of family life are considered in detail, such as the caste system of social insects, the complex social relationships in monkeys and apes, and parental care in crocodiles.

It is a pity that the text suffers so badly from the fact that several authors have contributed to the book. In one chapter the selfishness of courtship is rightly emphasised together with the conflict of interests between male and females and the diverse ways in which males compete with each other for the opportunity to mate. In the next chapter, however, we read all about harmonious pair bonds and are told that sneaky male mating strategies are not favoured because this would be harmful to the population. We even go right back to the old, and surely wrong, view that territorial behaviour exists to ensure that the population never grows too large and that fighting is ritualised for the good of the species.

The migration of animals has astonished man since the earliest times. The first explanation of the seasonal emigration of some species and the simultaneous appearance of others was the transmutation hypothesis. In summer, robins were supposed to change into restarts and hawks into cuckoos. Swallows were imagined to sleep all winter in the mud at the bottom of ponds while geese were thought to grow from barnacles. We now laugh at these old ideas but in *Animal Migration* (Orbis: London; £5.95) John Cloudsley-Thompson shows that the true explanations can be just as strange.

Tiny warblers flicker by night across thousands of miles of desert and ocean; spiders balloon about the skies on threads of silk; and salmon return from the sea to the exact streams in which they were born. There is a chapter on how the Sun, the stars and the Earth's magnetic field are used for navigation; and then the bulk of the book is divided into three sections: migration by air, land and water. Examples from all over the world are described with a clear and lively text, illustrated by abundant drawings, maps and colour photographs. All extremes are considered from the few centimetres that limpets wander round their

L. Harrison Matthews and Desmond Morris at London Zoo

Taken from *Animal Days*

home base on a rock to the vast wanderings of the shearwater over the polar seas.

There are good accounts of the migration of large mammals, the movements of plankton, fish, turtles and whales in the sea, and of bird, bat and butterfly migration in the air. It is emphasised that animal movements on such a vast scale, without respect for international frontiers, present serious problems for conservation. What is the use of restricting whale kills in one part of their range if the restrictions are violated when they migrate elsewhere? The book is an excellent portrayal of the wonders of migration but has little to say on its evolution or adaptive significance which is dismissed as "one of science's many unsolved mysteries". Migration is said to be a widespread "instinct" of advantage to the species, which obscures the important point that different individuals within a species may migrate in different ways. Readers are referred to Robin Baker's recent book, *The Evolutionary Ecology of Animal Migration* (Hodder and Stoughton: London, 1979) for an up to date account of this problem.

In *Colour for Survival* (Orbis: London; £6.95) Peter Ward looks at the ways in which colour influences animal behaviour and ecology. The book is illustrated with spectacular colour photographs most of which are by the author himself, who has travelled widely in Africa, Asia and Central America and has first-hand knowledge of the animals he describes. It gives us an exciting insight into the use of colour in animals for camouflage, mimicry, warning and display. There are some marvellous examples, such as the caterpillar that looks like the seed-packed excrement of a frugivorous bird and another that resembles a feather stuck to a wet leaf. The diverse uses of colour are described in insects, lizards, frogs, birds and large mammals. My favourite is the flower mantis from Borneo which has bright white petal-like extension of the body that lure flower visiting insects to their unsuspecting death.

Animals and their World (Blandford: Poole, UK; £8.95) by Mary Parker Buckles, which is subtitled "The astonishing story of how mammals live in their own ecological zones", left me mystified rather than astonished. The book is divided into chapters which deal with the major habitat types such as tropical and temperate forests, grasslands, tundra, desert, and the oceans. Every chapter begins with a brief ecological description and there then follows an idiosyncratic list of some of the mammals of the habitat with photographs and brief notes on each species. There is little relationship between the examples given and the ecological comments at the start of the chapter, and no attempt has been made to show how the different species are adapted to their various habitats. Because the book restricts itself entirely to mammals, there is no detailed account of how plants and other animal types influence mammalian life-styles and the reader is left in a sea of examples wondering what to conclude.

A second book which uses the same plan, but with great success, is *The Living World of Animals,* another outstanding publication by the Readers Digest Association (London; £9.95) in association with the World Wildlife Fund. The main part of the book is devoted to sections on the different ecological zones of the World and shows, with an authoritative text and an abundance of excellent colour photographs and diagrams, how animals make a living in their various environments. There are also chapters on animal distribution, evolution and behaviour, and relationships with man. The book manages to convey the beauty and magic of the natural world, from the cold white silence of the polar regions to the richness of the tropical forests, and at the same time gives an up-to-date account of our knowledge on animal adaptations. As such it must be one of the best natural history bargains on the market.

Desmond Morris has spent most of his life surrounded by animals, from student days with a laboratory that was filled with dozens of fish and birds to the years as curator of mammals at London Zoo where his office was a cage with a desk inside! In *Animal Days* (Jonathan Cape: London; £5.95) he recalls the people and events that have influenced his life. The result is a book that is great fun to read, a mixture of rich observations on animals and stories that are always amusing and sometimes hilarious. With varied interests that included film-making and paintings as well as Natural History, it was lectures by Niko Tinbergen and Konrad Lorenz that finally inspired Morris to take up zoological research. Baptised and then confirmed by these two great fathers of ethology, he moved to Oxford to study for a doctorate under Tinbergen. Here he made some fascinating observations on homosexual behaviour in sticklebacks and divorce in finches. He reared a pet crow that invaded nearby gardens and learned to squawk "Go away" in the cultured accent of an Oxford don. There were amusing meetings with J.B.S. Haldane and Julian Huxley and a wonderful story about Lorenz and a tame raven which I will not spoil for the reader.

Later on, in London, the author started the successful weekly television programme 'Zootime'. In front of the cameras the animals did not always behave as expected, like the time that the giant tortoise, roused to great activity by the warmth of the television lights, charged around knocking over the cameras and crew. The days at the Zoo also showed how sometimes hand-reared, captive animals could be reduced to hopeless mental hybrids, like the panda Chi-chi who preferred humans to her Russian spouse An-an. The famous artistic chimpanzee Congo and Guy the gorilla also rejected their own species as mates. Ethological research has helped us to understand the social and environmental needs of different species and Morris emphasises that modern zoos must provide these so that we can see the animals behave in their normal way.

There is, however, no substitute for observations in the field, although this can often be a time-consuming and frustrating occupation, as Alan Goodall shows in *The Wandering Gorillas* (Collins: London; £6.50). The book is mainly about the wanderings of the author in central Africa and the difficulties of life in the forest although we do get some occasional glimpses of the elusive gorillas themselves. By behaving like a gorilla, chewing leaves and beating his chest, Goodall was sometimes able to observe them at close range. On other occasions he experienced the terrifying bluff charges where a male would stop his advances only a couple of metres away! The gorillas are threatened by extinction, partly from local superstition (one group of six was stoned to death) but mainly by destruction of their natural habitat. Alan Goodall concludes with a plea for international aid to enable the central African governments to offset short-term economic losses and leave the forests intact so that these gentle giants are able to continue their wanderings in peace.

Nicholas Davies

Nicholas Davies is a Demonstrator in Zoology and Research Fellow of Pembroke College at the University of Cambridge, UK.

Intricacies of Nature

THERE seems to be no end to the flow of new books by experienced naturalists whose purpose is partly to educate the public in the intricacies of nature and partly to provide a forum for their authors' reminiscences. *A Natural History of Britain and Ireland* by Eric Simms (Dent: London; £6.95) has a flavour of the nineteenth century about it — accentuated by Robert Gillmor's exquisitely drawn vignettes at the head of each chapter. The author describes the very varied countryside of Britain in terms of its history and of its geographical differences. The book is divided into 15 chapters each of which deals with a different region that typifies a distinctive type of habitat. The book is also largely biographical, recalling the author's many experiences of wildlife in different parts of Britain. It does not make very easy reading — many of the accounts of specific localities, such as the Cheddar Gorge, consist largely of lists of species that the author has seen there. So much information is presented that the underlying theme of the book, an analysis of the factors that have produced the natural history that we see today, is frequently submerged.

Also by Eric Simms, *Wildlife Sounds and their Recording* (Elek: London; £5.95) goes in great depth into one aspect of natural history study, the recording of animal sounds. The book deals with detailed techniques and descriptions of recording equipment, the history of wildlife sound recording and something of the biological significance of auditory communication in animals. There is much interesting information about techniques and about the kinds of sounds that animals make. Unfortunately, the chapter on biological aspects of animal sounds is rather dated. In particular there is little mention of the highly fruitful use of playback experiments in which recorded sounds are played to animals in the field. This has been notably successful in increasing our understanding of the nature of territoriality in birds, competition between red deer stags, and mating strategies among frogs and toads, where synthetic sounds have proved very useful. The book contains a number of interesting photographs, particularly those of early recording equipment.

Encounters with Nature by Leslie Brown (Oxford University Press: Oxford; £6.50) is more revealing of the author than informative about wildlife. Consisting of a series of essays about encounters with animals that the author calls "golden moments" in his life, there are chapters on the aardvark, badgers, flamingoes and pelicans among others, seen mostly in East Africa and Britain. Some of the observations of animals in their natural state are evocative, exciting and informative but too much of the book is devoted to the author's opinions about the state of the world as he has found it during his life. The book is introduced by a series of contemptuous remarks about "scientists" and is punctuated throughout by comments that reveal that Leslie Brown yearns for the good old days of the British Empire when natural history was a hobby for a few privileged amateurs. While reading this book one inevitably finds that its rather sour, misanthropic tone contrasts with Gerald Durrell's much more amusing and sympathetic treatment of humans as well as animals. The book includes a series of attractive drawings by Doris Tischler.

In marked contrast to Brown's book, with its emphasis on more exotic and spectacular forms of wildlife, Ken Hoy's *On Nature's Trail* (Mitchell Beazley: London; £6.95; ALW: New York; $14.95) brings us back to the minutiae of wildlife in our immediate surroundings. This excellent and attractive book is a practical guide, telling the reader what to look for, where to find it and how to interpret what we find. It tells us what we can learn from animal droppings and tracks, what we can do to help injured or orphaned animals, how we can appreciate the complexity of life within a single tree, and much more besides. The book is generously illustrated with excellent photographs. As well as making a very good companion for any young enthusiast, this book should prove useful to teachers in search of ideas for nature trails and school field projects.

Another immensely useful book is *A Day in the Country* by John Gooders (André Deutsch: London; £5.95). This provides a pocket guide to naturalists and more casual observers of wildlife, telling them what they might see in any part of Britain. The book is divided into two parts. Part 1 lists all the National Parks, Forestry Commission areas, RSPB reserves, and many other official localities. Clear maps and lists of addresses make the planning of visits to such places a simple matter. Part 2, which takes up the greater part of the book, deals separately with eleven areas that together cover the whole of Britain. For each area there is information about footpaths, areas of outstanding natural beauty, wildlife parks and zoos, stately homes and many other places of interest to the naturalist. For each locality there is a list of the more interesting and unusual animals and plants that the visitor might expect to see. Illustrated by a number of very attractive sketches by David Thelwell, this book makes a truly valuable contribution to the enjoyment and appreciation of Britain's wildlife.

Tim Halliday

T.R. Halliday is Lecturer in Biology at the Open University, Milton Keynes, UK.

Wildlife of Europe

THE quartet of books reviewed here ranges from the broad canvas of the classification of the Animal Kingdom to narrower studies on groups and single species of carnivores. Naturalists will find the first useful, the rest diverting as well as informative.

Mammals: Their Latin Names Explained by A.F. Gotch (Blandford: Poole, UK; £5.95) clothes the dry bones of taxonomy for the benefit of those without a classical education. The scientific names of animals are, on the whole, indicative of their appearance, provenance or discoverers, and much is hidden from those who cannot derive the roots from which the names are composed. Thus the New World cottontail is known to zoologists as *Sylvilagus floridanus* which tells us that it is a 'woodland hare from Florida'. English names vary locally and lack the diagnostic precision of the scientific name.

The author of this book deals first with the phyla and subphyla of the whole Animal Kingdom from *Amoeba* to man, then with the vertebrates, down to orders in the case of mammals, and finally — the bulk of the book — with mammals down to families and selected species. The principles of nomenclature are explained, although it is surprising that the importance and adequacy of the first published description of a species are not more emphasised. At every step the Latin or Greek derivation of names is carefully expounded and — particularly valuable — a biographical note is given about explorers and scientists, after whom many animals are named. There are a few misprints and the odd contentious derivation; for example, I do not believe that the name *Didelphis* for the opossum refers to the pouch as a "secondary womb" (page 37): surely it indicates the double nature of the female reproductive tract in marsupials. In any case *Didelphis* does not have a pouch.

This book is a mine of information and illumination to naturalists who have used these names for years without understanding their import.

Carnivores of Europe by Robert Burton (Batsford: London; £8.50) is a timely evaluation at second hand of the status and prospects of the terrestrial, carnivorous mammals of Europe. These most interesting animals have been subjected to intense persecution by man, both as competitors for his domestic stock and as providers of warm and elegant clothing. Now that predatory animals are acknowledged to play a salutary rôle in the economy of nature, Mr Burton's book, giving up-to-date results of recent researches, helps us to assess probable future trends in numbers, both down-

Eris Simms with reflector microphone

Taken from *Wildlife Sounds and their Recording*

wards, due more now to fragmentation of habitats than to direct killing, and, surprisingly, upwards because of ill-judged introductions — for example, American mink and raccoon dogs. In addition, we have to face the possibility that extremely adaptable species, for example, the fox, are now flourishing in urban and suburban environments and could become a menacing carrier of rabies, which would be far more serious than the presumed agency of the badger in transmitting bovine tuberculosis.

The predator which seems to have the least hope of avoiding ultimate extermination, is the wolf. B.H. Lopez in his book *Of Wolves and Men* (Dent: London, £7.95) has produced an impressive and extensively documented survey not only of the natural history of this species but also of the significance of the wolf in hunting societies and of the bitter enmity that exists to this day between it and pastoralists. Most of the book is the outcome of tireless research among the literature but the author has been at pains to spend long periods in the field with Esquimaux in Alaska and to come to an understanding of how wolves are an intimate part of their world. If the wolf has to go, then this book will compose a worthy obituary.

Lastly, we have *Lutra, the Story of an Otter* by Philip Wayre (Collins: London; £3.95). This is the latest in the series *Collins Animal Lives*, each written by a specialist but with a presentation and an outlook which make easy reading for the layman and children. Because the otter is a declining species in England now, much sound and fury has been raised by protectionists to abolish otter hunting and to declare it a protected animal. The results of recent fact-finding surveys suggest that powerful causes of the otter's decline are pollution of our waterways and the increasing pressure of man's activities on them; in which case the establishment of the Otter Trust in Norfolk, of which Mr Wayre is Honorary Director, and the creation of quiet areas as refuges hold out the best hope of rehabilitating this very attractive animal. Mr Wayre's little book, which describes a year and a bit in the life of a bitch otter in East Anglia and is enlivened by the delightful sketches of John Edwards, will make many of his readers wish to do their bit in conserving the species.

Common hamster

H. N. Southern

H. N. Southern was until his recent retirement Senior Research Officer of the Animal Ecology Research Group in the Department of Zoology, University of Oxford, UK.

Seal saga

DURING the past century the grey seal has increased in numbers in British waters mainly because of the decrease in seal hunting by man. In the same period the status of most stocks of commercially valuable fish in the seas off the Scottish coasts, where the grey seal is most numerous, have declined due to overfishing by man. Seals and man both eat fish, but the quantity and quality of the seal's diet is, for a variety of technical reasons, inaccurately known. Assuming a grey seal eats 7 kg fish daily there is a postulated loss of some 56,000 tonnes per annum to the British in-shore fishery, estimated at £15 million. Unfortunately, the science of both the fishery and seal conservation aspects of the issue are riddled with assumptions and untested hypotheses.

These are the ingredients of a roaring conflict which has arisen and has already been staged between fishery and nature conservation interests in Orkney and North Rona during the breeding season of grey seals in 1978. A thoroughly objective review of the whole affair is difficult to obtain, firstly because of the formidable dossier of evidence and often conflicting expert comment and secondly, because of the emotive aspects of killing animals of such immense human appeal as seals. Nonetheless, in *Seal Cull: The Grey Seal Controversy* (Penguin: Harmondsworth, UK; 95 pence), John Lister-Kaye has come close to providing an account which is fair to both sides.

Lister-Kaye has provided a first class documentary of the grey seal-fishery issue in which he has systematically presented the information in a form which is useful to statesman, politician, scientist, fisherman, conservationist and interested layman alike. He writes not as a completely detached observer and is not afraid to state his own opinion on main issues and attribute blame or praise where he thinks fit. He also gives thought to the primaeval roots of the problem in "man and dog" relationships and very sensibly relates the conflict to the international scene and to harp seal harvest in Labrador from which the grey seal issue in Britain derives impetus. A set of personal interviews with prominent personalities shows them to be to a great extent in ignorance and disarray on major aspects of the controversy.

Seal pup

Taken from *Seal Song*

In conclusion there is a personal view in which the author, though hard hitting in some respects, does not damage his balanced treatment. The book does nothing but good in suggesting guidelines by which a compromise in grey seal conservation can be achieved.

In 1978 Orkney was a focus of national public interest because of the cull of grey seals there and at North Rona. In the arena Greenpeace and a local action group called 'Selkie' (Orcadian for 'seal') were pitted against Norwegian seal-hunters who were the contractors brought in by the then Secretary of State for Scotland, Bruce Millan. For every contestant in the field, there was at least one media man. The prospect of shooting, blood and confrontation brought the reporters and photographers in a swarm to Kirkwall.

Sue Flint, a seasoned campaigner for good causes in Orkney, was a moving spirit in the local Selkie group and painstakingly

Forthcoming publications from
COLD SPRING HARBOR LABORATORY

MOLECULAR BIOLOGY OF TUMOR VIRUSES, 2nd Edition

Completely revised in three parts

Since its publication in 1973, *The Molecular Biology of Tumour Viruses* has come to be regarded as a classic text in its field. To maintain this book as the basic reference source it has become, the Cold Spring Harbor Laboratory will publish a complete revision, in three separate volumes, over the next 12 months. This expanded edition will report on the most recent work of the leading researchers in the rapidly advancing study of tumor viruses.

DNA TUMOR VIRUSES
Part 2 of Molecular Biology of Tumor Viruses

Monograph 10B

Edited by **John Tooze,** *European Molecular Biology Organization*
945 pp., (approx.), illus., index
Cloth, $55 0-87969-126-3
February 1980 LC 79-19882 CIP

DNA Tumor Viruses describes the cellular microbiology of polyoma virus, SV40, adenoviruses, papilloma viruses, human papovaviruses, adenovirus-SV40 hybrids, and the herpesviruses. The book discusses in detail the structure and composition of each of these viruses, their replication, and their interactions with semipermissive and nonpermissive cells leading to transformation. The volume should be invaluable to advanced undergraduates, postdoctoral students, and research workers as a source of information on the molecular biology, biochemistry, and cellular biology of these viruses; to anyone interested in these viruses in transformation as a model for studying tumorigenesis or for using these viruses as cloning vehicles; and to medical doctors interested in the basic methods of carcinogenesis.

Appendixes containing the following DNA sequences: SV40, Polyoma, Human Papovavirus BKV, and Adenoviruses 5, 7, and 12 were contributed by A.R. Buchman et al., B.E. Griffin et al., I. Seif et al., J. Maat et al., R. Dijkema et al., and H. Sugisaki et al.

RNA TUMOR VIRUSES
Part 3 of Molecular Biology of Tumor Viruses

Monograph 10C

Edited by **Robin A. Weiss** and **Natalie M. Teich,** *Imperial Cancer Research Fund Laboratories*
Proposed 1980

Contents
General Introduction: Historical background. Classification. Pathology. Structure. Replication and transmission.
Retrovirus Groups: Compendium of retroviruses. Biological characteristics. Modes of assay. Oncogenic and pathogenic potential.
Viral Genome and Genetics: Structure of genome. Other viral nucleic acids. Definition of viral genes and their products. Organization of genomes. Nondefective and defective viruses. Helper viruses. Phenotypic mixing. Recombination. Viral mutants.
Replication Cycle: Adsorption and penetration. Provirus hypothesis. Synthesis and integration of viral DNA. Restriction maps. Transcription and processing of viral RNA. Translation. Host factors in replication cycle.
Viral Proteins and Assembly: Biosynthesis, cleavage, and processing of virion proteins. *gag*, *pol*, and *env* products. Virus assembly and maturation.
Transmission
Pathogenesis I: Retrovirus diseases. Oncogenesis. Anemia. Neural disease. Osteopetrosis. Viral oncogenes.
Pathogenesis II: Oncogenesis in vivo. Host response, genetic and immunological.
Conclusions and Perspectives: Human retroviruses.

THE TRANSFORMED CELL
Part 1 of Molecular Biology of Tumor Viruses

Monograph 10A

Edited by **John Tooze,** *European Molecular Biology Organization*
Proposed 1980

The aim of this book is to provide a comprehensive treatise on the properties of cells in culture, especially as they relate to the study of tumor viruses and oncogenesis.

Contents
History of Cell Culture
Molecular Biology of Eukaryotic Cells
DNA structure/replication; Transcription-processing; Translation; Cytoskeleton; Cell surface; Intermediary metabolism and internal signals
Transformation and Selection
Cytoskeletal and Surface Changes
Growth Factors and Hormones
Tumors and Transplantability
Proteases

ENTOMOLOGY

The first authoritative and comprehensive account of all aspects of the insect egg

Biology of Insect Eggs

Published in 3 volumes.
H. E. Hinton †

***Save US$80.00 (£40.00) with the pre-publication offer – valid on all orders received before 31 March 1980.**

*** 1500 pages, including detailed illustrations, subject and species indexes, and over 6000 references.**

This unique reference book is the definitive work in its field with an encyclopaedic coverage of subjects of major importance for academic zoologists, agriculturalists and those concerned with pest control. It takes two approaches. The first consists of a study of the role of specific physiological structures and aspects of behaviour in egg biology throughout the class. The second comprises a review of the biology of eggs in the various orders of insects. This work wil not only inform and guide entomologists with different interests throughout the world of the insect egg, but will also provide a stimulus to further investigation into a fascinating area of study.
This work is extensively illustrated throughout with hundreds of original high-quality electron micrographs and line drawings. Many were personally prepared by the author and are previously unpublished.

Volume 1
GENERAL BIOLOGY – begins with a brief and purposefully controversial discussion of important general points including egg size, metamorphosis, apolysis and ecolysis. It continues with a review of the factors affecting the number of eggs, oviposition sites and responses, and considers (among other topics) the structure, physiology and evolution of egg respiratory systems.
Contents: Introduction: Number of Eggs. Oviposition. Respiratory efficiency of egg plastrons. Hydropyles and water relations. Colleterial Glands. Oothecal and shell proteins. Enemies of eggs. Defensive devices. Parental care. Techniques.

Volume 2
THE EGGS OF INSECT FAMILIES – presents more general considerations of the structure of the female reproductive system, vitellogenesis and the development of the micropylar complex. It is chiefly devoted to accounts of eggs found in each insect order.
Contents: Ephemeroptera. Odonata. Dictyoptera, Isoptera and Zoraptera. Plecoptera and Embioptera. Orthoptera. Cheleutoptera. Psocoptera. Phthiraptera. Thysanoptera. Hemiptera (Hemoptera, Heteroptera). Megaloptera and Neuroptera. Coleoptera. Hymenoptera. Trichoptera. Lepidoptera. Mecoptera. Diptera.

Volume 3
Contains the subject and species indices. The extensive bibliography of over 6000 references includes many references to each particular topic and provides extensive, easy coverage of such a wealth of literature.

1500 pp Illustrated Over 6000 literature references
Sold only as a 3-volume set. Due Autumn 1980
Pre-publication offer valid on all orders received before 31 March 1980

AGRICULTURE

*Irrigation of Field and Orchard Crops under Semi-Arid Conditions

Editors: J Shalhevet, A Mantell, H Bielorai & D Shimshi

A summary of field experiments conducted in Israel which were designed to establish the optimum irrigation regimen for various field and orchard crops, and to increase water-use efficiency.
110pp 1979
0 08 025511 6 **US $9.00 £4.50**

*Irrigation Equipment Manufacturers' Directory, 2nd Edition

Editor: The International Irrigation Information Center, Bet Dagan, Israel

This book provides an alphabetical listing of over 400 manufacturers of irrigation equipment, giving details of the names and addresses of all their offices and products. It includes a classified equipment index and a country index.
312pp 1979
0 08 025512 4 **US $50.00 £22.50**

*Quality of Irrigation Water

I Shainberg & J D Oster

An up-to-date summary of present knowledge on salinity and sodium problems resulting from irrigation. It provides a concise account of the basic principles of water, soil and crop in relation to salinity and soilicity, as well as practical suggestions for irrigation management for salinity control.
A table of the salt tolerance of many crops is included.
72pp 1979
0 08 023822 X **US $11.00 £5.50**

NEW PUBLICATIONS

INVERTEBRATE ANIMALS
COLLECTION & PRESERVATION

Compiled by R. J. Lincoln & J. G. Sheals

Morphology, classification and biology of all invertebrate groups, except for insects. Collecting equipment, techniques and preservatives. A comprehensive well-illustrated manual for undergraduates, research workers and operatives 'in the field'.
Co-published with Cambridge University Press.
Paperback £3

BRITISH MARINE AMPHIPODA:
GAMMARIDEA

R. J. Lincoln

Descriptions and figures of all 271 species recorded from British coasts and the adjacent continental shelf.
Hard bound £50

PARASITIC COPEPODA OF BRITISH FISHES

Z. Kabata

Keys to, and descriptions of, all species known to parasitize fishes in British waters to time of writing. Over 2,000 illustrations.
A Ray Society publication.
Hard bound £30

BRITISH TORTRICOID MOTHS
TORTRICIDAE: OLETHREUTINAE

J. D. Bradley, W. G. Tremewan & A. Smith

The second of two matching volumes covering all 319 species of Tortricoid moths found in the British Isles. The 22 colour plates in this volume depict 500 individual moths and were specially prepared by Brian Hargreaves.
A Ray Society publication.
Hard bound £40

BRITISH TORTRICOID MOTHS
COCHYLIDAE & TORTRICIDAE: TORTRICINAE

The companion volume to the above, 1973.
Hard bound £20

Catalogues of all British Museum (Natural History) publications free on request.

The Darwinian Revolution

Science Red in Tooth and Claw

Michael Ruse

The Darwinian Revolution is a panoramic and comprehensive review of this pivotal episode in the history of science, setting Darwin's ideas, and those of his progenitors and competitors, in the context of Victorian religious, social and scientific attitudes. Ruse gives an overview of the intellectual climate of the Darwinian age: religious beliefs and their relation to the science of the day; the scientific community, particularly the established societies whose help or rejection often arbitrated scientific 'truth'; social and political factors; and the thinking of the various branches of science from which Darwin's *Origin* emerged as a logical extension. December 1979, £12.00.

Charles Darwin and the Problem of Creation

Neal C. Gillespie

In this book Gillespie analyses the conflicting creationist and positivist theories of science, Darwin's conversion to the theory of evolution, the role played by Darwin's religious beliefs in the *Origin of Species*, and shows how his opposition to creation rested on theological as well as scientific grounds. November 1979, £9.90.

Genesis & Development of a Scientific Fact

Ludwik Fleck

edited by Thaddeus J Trenn and Robert K Merton
Translated by Fred Bradley & Thaddeus J Trenn
Foreword by Thomas S Kuhn

First published in German in 1935, this monograph argues that every scientific concept and theory, including Fleck's own, is culturally conditioned. As Thomas Kuhn observes, "Though much has occurred since its publication, it remains a brilliant and largely unexploited resource." December 1979, £10.50.

wrote a diary of events which appears in *Let the Seals Live!* (Thule Press: Sandwich, Shetland; £5.50). This is the story from the Selkie side of the action which, understandably, portrays their action as verging upon the heroic. It is primarily about people, secondarily about seals. If Mrs Flint did not write with such a light touch and with such humour and feminine charm, the book could be a tedium of trivia enlarged to assume an importance far beyond reality by the ambient tension which gripped Orkney at the sight of the Norwegian sealer, *Kvitungen,* closely shadowed by Greenpeace's vessel, *Rainbow Warrior.*

However, much more can be read from this book than a faithful account of a local and national campaign to save the Orkney and North Rona seals from slaughter. It shows clearly the delicate balance which is struck between the rational behaviour of ordinary people and that of the same moving on a sense of bitter outrage. It also shows that the same local people can expect strong national and international support, not just in words but in action on the spot, in very difficult conditions. It also shows how extended, exhausted and near to collapse was the local expeditionary force. The book has many mistakes and shows all the signs of having been rushed. It is, however, something of a latter-day Orkney saga — both informative and entertaining.

Seal Song (Allen Lane/Penguin: London and Harmondsworth, UK; hardback £4.95, paperback £2.50) is a sensitive portrait of the harp seal created in words by Brian Davies with photographs by Eliot Porter. Davies is the executive director of the International Fund for Animal Welfare which has been, through his personal energies, responsible for the campaign against the annual hunt mainly of harp seals off Newfoundland and Labrador.

The book, produced in 'coffee-table' style, described the author's commitment to the battle against the cruelty inflicted by mankind upon wildlife for economic gain. He finds in the harp seals the quintessence of natural beauty, evolutionary adaptation and a subtle psychological, perhaps mystical relationship between man and beast. His reactions are instinctive of a person who is repelled by any sense of pain or bloodshed and there could not be a more vivid subject for such reactions than the slaughter of the fluffy, white seal pups and their sleek, silken dams in the crazy, white world of the sea-ice.

Inevitably, therefore, this is an account which is heavily charged with emotion; while providing some salient scientific information and assessment of the social and political issues, the author makes a direct case for the cessation of the seal hunt on grounds which are mainly humanitarian. His fears for decimation and possible extinction of the harp seal are, however, very real when seen against the potential for exploitation embodied in a sealing vessel such as that shown in this book.

There are compelling descriptions coupled with excellent full-page colour photographs of the harp seals both on the ice floes and in the strange phantom light in the sea under the ice. Porter's photographs provide superb contrast in texture; the soft, downy warmth, black muzzle and watery, wide-awake eyes of the pups seen against the hard angular shapes of the sea-ice.

The book concludes with a personal account of efforts made by Davies and others against great odds to fly the world's press to the scene of the hunt, in which he risked his life. An outstanding piece of publicity against the seal hunt, it is short, easily read, lavishly illustrated and has instant impact.

A seal emerging from the sea is like a stranger from another world; yet for a few crucial days each year the grey seal must come ashore above high water mark to give birth and mate. They are then so vulnerable to hunters and available for study by scientists. In the 1930s the late Sir Frank Fraser Darling started the scientific work in the Hebrides and this was continued after the war by Dr Leo Harrison Matthews and his friends Professors E.C. Amoroso, Richard Harrison and the late Humphrey Hewer. They became fascinated by the behaviour, reproductive anatomy and physiology of both the grey and common seal and spent many enjoyable days in the field and laboratory piecing together their biology, particularly the evidence of delayed implantation of the blastocyst, possibly related to the spring moult in the grey seal.

The story is told in the style of a biographical novel by Harrison Matthews in *The Seals and the Scientists* (Peter Owen: London; £7.50). A series of conversation pieces with his zoologist companions in strange places are interspersed with contrasting descriptive sketches of the Welsh Islands and the Wash. There are some exciting moments in coming face to face with the heroine — a grey seal cow called Mrs Mopp!

The discussions of the academics are full of accurate scientific information presented systematically in informal guise. However, the book deals only with the early years of a period of great expansion in seal biology in Britain and the relationship of seals to sea fisheries. That a book of this title and character should have been published in 1979 without greater mention of the seals and fishery issue and some of the main personalities (because it is about people as well as seals) is a great pity. Though sprinkled with many technical and scientific terms, the book will be enjoyed by both naturalist and layman.

J. Morton Boyd is Director for Scotland of the Nature Conservancy Council, Edinburgh, UK.

Living with cetaceans

SCIENTISTS have seldom been able to study living cetaceans directly, but have usually had to work like detectives building a story either from clues washed up on the beach or from inspecting victims of the whaling industry in order to infer something of their lives from corpses. Unfortunately, the popular tradition of celebrating the careful deductive approach of the detective hero has not become established among popular books on cetaceans. Instead, the cetacean literature has suffered from authors who have taken advantage of the lack of knowledge about these mammals to speculate freely and to present these speculations as the truth.

Whales, Dolphins and Porpoises by Ronald Lockley (W.W. Norton: New York; David and Charles: Newton Abbot, UK; $14.95, £6.95) is a case in point of this unfortunate tendency. The book is written in a careless, chatty style and its organisation is confused. Many sections seem to have little to do with their headings. For example, the section entitled "Anatomy and physiology" concentrates on cetacean intelligence, bouyancy, diurnal rhythms and sleep. The rough draft quality of this book is by no means as harmful as the fact that many statements are either confused or false; this problem is aggravated by the fact that not all references quoted in the text are listed in the bibliography.

Lockley's evaluation of the cetacean literature is typified when he maintains that dolphins can probably perceive our thoughts by telepathy and that baleen whales are known to echolocate; or when he states: "They [cetaceans] display almost every human emotion you can name — in short, cetaceans are almost human.". Lockley commits enough serious errors of fact that I cannot recommend this book to anyone who wants to be able to distinguish what is known about cetaceans from what might be true or is simply false.

This is a shame, for the book contains many beautiful and interesting photographs as well as a useful set of descriptions and illustrations of most species of cetaceans. Lockley's account of interactions between humans and cetaceans, both cooperative and predatory, is detailed and is much more sound than his attempt to describe cetacean biology.

Wake of the Whale (Hutchinson: London; Friends of the Earth: New York; £15.95) is not a book about whales, but rather describes the work of one of the finest photographers of whales, Bill Curtsinger. The book is organised around a collection of superb photographs taken

by Curtsinger of marine mammals around the world. The large format of the book enhances the fine reproduction of these photographs, which comprise half of the book. Wild cetaceans are among the most difficult of photographic subjects, and this difficulty tells, for the pictures of cetaceans in this book cannot compare with those of seals — either in composition or clarity. In part because of these difficulties, this collection of photographs is eloquent evidence of the persistent and devoted skill of Curtsinger as a photographer.

The text accompanying these photos exhibits a curious ambiguity of purpose. Not only does the author, Kenneth Brower, describe Curtsinger's adventures with cetaceans, but he also devotes equal attention to details of Curtsinger's personal life. The book does contain many statements about the biology and natural history of whales; these are occasionally in error and are tossed off carelessly as if the facts of whale life are peripheral to the main theme of the book. Brower is obviously fascinated with the issue of what kind of person would devote his life to living on the remote edges of the Earth, constantly struggling for fleeting encounters with marine mammals. Yet Brower never directly acknowledges this hidden agenda of the book and leaves me wondering about his purpose. Does he simply want to extol the virtues of whales as seen through Curtsinger's eyes and camera, or does he want to say something more general about the importance of wildness and mystery in all of our own lives? In spite of this ambiguity, *Wake of the Whale* should interest anyone who wants a beautiful collection of marine mammal photographs accompanied by a description of what it is like to live near these animals.

Peter Tyack

Peter Tyack is a graduate student in animal behaviour at Rockefeller University, New York.

World fisheries

Food from the Sea. By James Nicolson. Pp.205. (Cassell: London, 1979.) £6.50.

THIS book, which is written primarily for the layman and the fisherman, begins with a brief account of aspects of the marine environment which are of importance to fisheries and goes on to consider some of the notable features of fish populations such as reproduction, migration and short- and long-term fluctuations in stocks. This is followed by a chapter which describes some of the main food organisms harvested from the world's oceans. Obviously it is impossible in a book of this size to deal with every important species but in many respects I felt that there was a certain lack of balance in this chapter. For example, the five species of Pacific salmon fished by five nations are only mentioned in passing, whereas the three dogfish of European waters, only one of which has any commercial value, have two paragraphs devoted to them.

In chapters 3 to 7 the author traces the development of the world's fisheries from the earliest times, through the astonishing technological advances of the last hundred years, to the present day. These chapters are well researched and the historical account, laced with many interesting anecdotes, clearly shows that "the history of fishing is a story of human ingenuity and remarkable technological achievement — marred by carelessness and a wanton misuse of some of the richest sources of food in the world".

He then considers the question of overfishing and describes how the development of fleets of ocean-going freezer trawlers in the 1950s and 1960s had a devastating effect on many of the worlds already over-exploited fisheries. In many cases it was the industrial fisheries which suffered most and as soon as one fishery became uneconomic the fleets simply moved on to uncontrolled exploitation of yet another resource. He then deals with the systematic destruction of the north-eastern Atlantic herring fisheries and discussed the conflict between the traditional fishery on the adult stock with the fishery on the young fish on their nursery grounds for reduction to meal and oil. He then traces the history of the scientific basis for fisheries management and the setting up of the various international organisations with reponsibility for conserving the stocks. He is critical of the scientists, the International Council for the Exploration of the Seas and the North-Eastern Atlantic Fisheries Commission for their failure to conserve the herring stocks.

The author is undoubtedly aware of all the problems involved in the management of a stock but it is unfortunate that some space could not have been devoted to considering the differences between growth overfishing and recruitment overfishing. The latter is an important factor in herring and indeed many other pelagic species which grow little in their adult lives, and the failure of the scientists to understand the relationship between recruitment and stock size was a key factor in the collapse of the herring fisheries.

Looking to the future the author considers the role of fish farming as a means of increasing food production from the sea. Throughout the book one gets the impression that, while not denying that fish meal production has a role to play in utilising the resources of the seas, the author would prefer to see a greater emphasis on the use of fish for direct human consumption. It is therefore surprising that he is not critical of fish farming as practised by most of the developed nations in which fish meal is used to produce luxury protein in the form of species such as salmon and trout.

I have no hesitation in recommending this book to anyone with an interest in the fishing industry, especially to anyone who wishes to understand the background to the present problems facing the industry and the controversy involved in the formulation of a common fisheries policy within the European Economic Community.

J.D.M. Gordon

J.D.M. Gordon is a Principal Scientific Officer at the Dunstaffnage Marine Research Laboratory, Oban, Argyll, UK.

Sea guides

Marine Life, by David and Jennifer George (Harrap: London; £16) is an extremely well produced book describing marine invertebrates. The centre section of the book consists of 1,300 colour photographs of high quality, while the two end sections describe the various invertebrate phyla down to family and a "representative species". There are a number of line diagrams in these sections of the book. Technical terms are reduced to a minimum and a short glossary is provided. Nevertheless, readers without zoological knowledge might find the book a little daunting. It is not unlike some of the modern gardening books, with a centre section of colour plates and a fairly technical description at either end.

Although the publishers claim it is an encyclopaedia, it could not be used for identification of different groups down to species. Nor could it be considered as "an indispensable work of reference." It is true that scuba diving has enabled biologists and laymen to see animals in their natural state but detailed identification is still done from fixed specimens even if they are "distorted and colourless on the laboratory shelf." The authors seem to take a rather simplistic view of identification, although David George is on the staff of the Natural History Museum. I agree with the Foreword that it is a fine book but it is not a field guide in the sense that it could be put in one's pocket. It is excellent value for £16 and worth a place on the library shelf of any institution, or anybody interested in marine invertebrate zoology, but it should fulfil the role of a colourful adjunct to a systematics course rather than a substitute for the rigours of formal systematics.

Kenneth Gosner's *Field Guide to the Atlantic Seashore* (Houghton Mifflin: Boston; $12.95) would just fit into a capacious pocket. It lists 907 littoral invertebrates and 140 seaweeds from the NW Atlantic from the Bay of Fundy to

Cape Hatteras, although some species extend beyond these limits. The centre section consists of 64 black-and-white and colour plates which are drawings of the species; the two end sections consist of descriptions of the species with notes on seasonal occurrence and where they are to be found. There is no attempt to divide the species within phyla. At the beginning of the book there are introductory chapters on how to use the book, nomenclature, collecting and preserving specimens, labelling, distribution and habits and zonation, and at the end a glossary. Such a book must be of limited use to collectors on British or European seashores, especially when goods books are already available (see *Nature* **264**, 587, 1976).

David Bellamy is well known as a botanist-cum-broadcaster. His book *Half of Paradise* (Cassell: London; £7.95) bears no resemblance to the other two; it is a breezy and well illustrated account of two Joint Services underwater expeditions to the Chagos Archipelago in the Indian Ocean between 1972 to 1975. They appear to have been a combination of a moderately serious scientific enterprise, a Services training exercise and for gathering material for a BBC documentary programme. Results were obtained on the growth of coral reefs, migration and breeding of seabirds and on the flora and fauna of the islands. The expedition charted the islands, dived on wrecks, had brushes with sharks and robber crabs, rats, mosquitoes and sand flies and generally had an eventful time. The book has a Foreword by Prince Charles, who clearly would have enjoyed being a participant. This is a book worth borrowing from the public library if one can 'take' David Bellamy's mildly irritating style of writing. **J.H.S. Blaxter**

J.H.S. Blaxter is a Senior Principal Scientific Officer at the Dunstaffnage Marine Research Laboratory, Oban, Argyll, UK.

Fish guides

TWO recent guides to British and European fishes could scarcely offer a greater contrast. Judging from their titles and general appearance, L. Cacutt's *British Freshwater Fishes: The Story of their Evolution* (Croom Helm: London, £6.95) is a serious and (one anticipates) authoritative study of the evolution and biogeography of Britain's freshwater fishes, *Fishes: Freshwater and Marine Species* (Chatto and Windus: London; paperback £2.50) second is slighter, being a collection of colour photographs with modest text fitted into matching spaces opposite the picture. One is written by a journalist professionally interested in fishes, the other by an Austrian ichthyologist and translated and adapted by an English zoologist. The first is pretentious, filled with errors and fails in its objective of presenting a coherent account of the fish fauna; the second is as authoritative as its appearance is modest.

Terofal's little book, a *Chatto Nature Guide* contains approximately 120 colour photographs of living fishes, mostly taken in aquaria. The standard of photography is high and the colour reproduction good. Most of the European freshwater fishes are included but the coverage of marine species is less good. Colour photographs of many of the Danubian species have not been reproduced before in English texts and this is a strong point in the book's favour. The text is organised in systematic order, and for each species included there are short, rather telegraphic, accounts under headings of, characteristics, distribution, habits, and diet, although the use of these headings is not consistent throughout. Errors are few; for example, the nine-spined stickleback has been placed in the genus *Pungitius* for several years but is here referred to as *Gasterosteus pungitius*, and the photograph opposite the caption line, *Molva molva*, is of a torsk, *Brosme brosme*. Such minor errors apart, this is an excellent book and should help fill the stocking of many an angler this Christmas — and probably those of quite a few ichthyologists also.

Of Cacutt's book I wish I could say the same. It starts with a typographical error on the fifth page of the prelims with "A fossile pike" a standard which continues more or less throughout. "Spiney-finned Fish" are referred to so often that I had to resort to a dictionary to check that it was not a permitted alternative for spiny.

The author's intention is said to be to present "the broad spectrum of the multi-million year-old story of Britain's freshwater fishes". There are also discussions of fossil fishes and some geology, and potted accounts of continental drift and of the ice ages, of which the last has some relevance to the subject. The major part of the book, however, is a collection of accounts, of British freshwater fishes, species by species, with heavy emphasis on anglers' interest in weights and records, and on behaviour.

The author's familiarity with the subject seem sketchy. On the interesting biogeography of the Irish freshwater fishes we are told on page 60 that the bream, loach and rudd are indigenous to Ireland and then on page 128 that the bream was introduced, while on page 110 the rudd is omitted from another list of indigenous species. In fact, none are indigenous to that island. The author shows a positive genius for getting terms and names wrong, for example, andronomous for anadromous, Roderick Imprey Murchison for R. Impey Murchison, and *Erythrophthalmus scardinius* for *Scardinius erythrophthalmus*. This trait provides a little light relief in places as on page 12 where Darwin's "*Evolution of the Species*" is described as a classic example of a "stodgy" scientific book, "sheer drudgery to read". Alas, Darwin wrote no such book.

This book certainly cannot be recommended, except perhaps as an example of the old saw that a little knowledge is a dangerous thing.

Alwyne Wheeler

Alwyne Wheeler works on fishes in the British Museum (Natural History), London, UK.

Happiness is helical

TWO recently published books dealing with aspects of the study of molluscs, they are as different as roast beef and candy floss. *Sea Shells: A Naturalist's and Collector's Guide* (Phaidon: Oxford; £6.50), by Peter and Patricia Newell, is very pretty; it has a saccharin sweetness about it and it will appeal to shell novices. But such a diet cannot satisfy for long. Although this book contains many colour pictures by famous invertebrate specialists like Douglas P. Wilson and Heather Angel, the captioning is poor. The information given is sometimes inaccurate (the beautiful nudibranch illustrated on page 23 is not even correct to the nearest family), and the provenance of the specimens illustrated is not uniformly helpful. The text is undistinguished and there is on page 42 a "Key to the most common classes of mollusks" which will confuse any budding shell expert; it should have been left out. *Sea Shells* is a pleasant coffee-table book, no more.

M.P. Kerney and R.A.D. Cameron's authoritative *A Field Guide to the Land Snails of Britain and North-west Europe* (Collins: London; £5.50) in the Collins Field Guide series is the roast beef. It may require more effort to chew and swallow, but the nutritional benefits are substantial. This is the first compendium to deal comprehensively with the land snail shells of the whole of North-west Europe. There are, of course, fairly good guides in existence, dealing with the land molluscs of individual countries, but some of these are out of date, or so massive as to deter even the professional. The present guide describes and illustrates the 279 known species (plus a few stowaways which have turned up in greenhouses) in a way which will satisfy even the most demanding specialist; at the same time it can be used and enjoyed by

those with little or no previous experience.

The land mollusc fauna increases in richness from north to south in the area covered by the guide. Iceland has only 25 or so species, southern Britain about 100 species, and parts of France over 130 species. This kind of faunistic recording is fascinating, and is based upon data accumulated by a vast army of amateur and professional devotees. Outside ornithology, there are few areas of practical biology where the amateur can play a more effective part than malacology, the study of molluscs. The authors give us all the information we need to enable us to join in the fun. There are chapters on the shell, soft parts of the body, life-history, feeding habits, classification, and an excellent introduction to finding, collecting and preserving land snails. Kerney and Cameron will win the gratitude of all those professionals who routinely identify and handle land molluscs, for surely many young malacologists will be recruited through reading this guide. I should like to see a copy in every haversack, along with the usual maps and ornithological field guides. **T.E. Thompson**

T.E. Thompson is a professional malacologist whose most recent appointment was Visiting Professor of Biological Sciences, Florida Institute of Technology.

For the entomologist of the future

THREE recently published popular books on insects differ a good deal in their scope and treatment of the subject. Professor Karl von Frisch, a Nobel Laureate honoured for his work on bee behaviour, is well known to a wider audience of naturalists for his popular work, *The Dancing Bees*, a book which, to my mind, is very much more interesting than the one now under review. *Twelve Little Housemates* (Pergamon: Oxford and New York; hardback £8, paperback £2.50) is a revised and enlarged version of a book on ten groups of insects found in and around houses, and includes accounts of the house-fly, mosquitoes, fleas, lice, bed bugs, clothes moths, cockroaches, ants and aphids. The species are well chosen and their biology is described accurately and simply, in a way understandable by the complete layman or by a child. The book is hardly detailed enough to satisfy the serious amateur naturalist or the budding entomologist, and the rather forced humour of the text and the Victorian air of many illustrations are not likely to win over a sophisticated reader. But von Frisch is mildly discursive and despite some of the naively phrased passages he is able, in his own words, "to show that there is something wonderful about the most detested and despised of creatures".

Dr Carson Ritchie, an archivist and historian by training, believes, in his *Insects: The Creeping Conquerors and Human History* (Elsevier/Nelson: New York; $7.95) that insects have had crucial effects on human history and sets out to describe some of these. For better or worse, the book is largely a collection of historical anecdotes, rather brashly presented and strung together in a loosely chronological sequence, on such subjects as silk production, singing insects, insects as human food, and insects in medicine and art. Entomology is not really one of the author's strong points and the occasional howlers provide additional surprises in a book already packed with stories intended to excite, intrigue, startle, alarm or confound the reader. Entertaining snippets of information abound on every page. Did *you* know that machinery able to produce 318,504,960 yards of silken thread per day had been installed in Derby in 1718? Or that France imported 57 million medicinal leeches in 1823? (By an elastic definition of the Insecta, Dr Ritchie manages to include earthworms, spiders, palolo worms and *Teredo* among his creeping conquerors.) And there are illustrations of all manner of things from Maori tatooing chisels to what I presume are geisha girls entranced by the music of cicadas. But not all readers will be convinced by claims that the silk industry led to the Industrial Revolution or that *Phylloxera* played an important part in the downfall of Napoleon III. Certainly the scholar will regret the more uncritical passages and the almost complete absence of references in support of so many facts.

By contrast, *Insects: An Illustrated Survey of the Most Successful Animals on Earth* (Hamlyn: London and New York; £10), by Brian Selman *et al.*, is a straightforward account, lavishly illustrated with more than 200 colour photographs, line drawings and diagrams. No doubt it will be the coloured illustrations which will fascinate the layman. They certainly convey a most vivid impression of the diversity of insects and, by often portraying things much larger than life, they enable anyone to see insects exactly as the professional entomologist views them through a stereoscopic microscope. The quality of reproduction is generally high and some are superb portraits of handsome subjects with gleaming cuticles, quivering wings, and alert activity suggested by every bristle! The text that accompanies these pictures is written by a group of specialists and deals in turn with the evolution and distribution of insects, their structure, physiology and development, their habitats and modes of life, their impact on man, and their classification. All these are discussed in an authoritative, modern way, and without over-simplification. The result is a book which depicts very successfully the great variety and biological interest of the insects. It can be enjoyed by a 14-year-old who is keen on biology, but it will also serve as a reference book for all but the more specialised undergraduate courses in entomology. Not cheap, but a good Christmas present, especially for the entomologist of the future.

R.G. Davies

R.G. Davies is Reader in Entomology at Imperial College, University of London, UK.

Traditional remedies

THE great majority of the world's population is poor and their medicines are traditional, being mainly plant or animal in origin. These people either care for themselves when ill or use traditional healers. In both cases the sources of their remedies are well known, and children learn from an early age which plants can or cannot be used, and for what purposes. It was realised some time ago that the plants used in these traditional forms of medicine might well repay scientific investigation and there are various projects underway (and no doubt afoot) for doing just that. This is a long way, however, from the current fad for using herbal remedies instead of modern pharmaceutical products. The fashion seems to be confined to the English-speaking world, no doubt because the inhabitants of mainland Europe have never stopped using traditional remedies for a variety of conditions. This may well be due to the fact that there are still peasants in these countries who know and collect the plants. Would that we had a reasonable reservoir of people here who could do the same, but I am afraid this is not the case. This raises a very important point. The books reviewed here are designed for amateurs, not professional botanists and plantsmen. It is essential that either the plants listed should not be harmful or the descriptions so detailed and clear that mistakes should not occur, within the limits of human fallibility. This is especially important when describing members of the Umbelliferae (parsley) family, most of which look alike to the layman and include both very useful herbs and extremely poisonous plants.

Nicholas Culpeper's Complete Herbal and English Physician (Gareth Powell: London; £15) is a facsimile of the 1826 edition but was first published in the seventeenth century, when medicines were

based on plants and folklore. The plants are listed alphabetially under common names, with a description of uses, habitat and time of harvest. Culpeper also gives the sign of the zodiac with which each plant is associated and the effect this has on its use. He was greatly criticised in the past for his interest in astrology — now only of historical interest. He also lists the temperament of the herbs — hot or cold — and the effect this has on the body. There are sections on gathering and drying the herbs, and on the preparation of medicines. The section of cures for various ailments are not all of plant origin; if you rub black snails on a wart and then stick the snail on a blackthorn twig, the wart will go. The archaic English makes this book difficult to read; and although the illustrations are pleasant, its value is historical rather than practical. A good present for devotees of the past.

Maurice Mességué is a practising herbalist, much of whose knowledge is a family inheritance. His book, *Health Secrets of Plants and Herbs*, has been translated from the French (Collins: London; £7.95) and is somewhat flowery in style but down to earth and practical in content: he knows and uses the plants he writes about. He sensibly keeps the list of plants to a hundred readily available ones, enough as he says for the normal needs of a family. He also omits nearly all those with poisonous or irritant properties; and where they are listed, he is careful to say how they should or should not be used. Reading this book has been a pleasure, even if one is left feeling that intestinal worms are rather prevalent in southern France. One matter which will not meet with complete approval in this country is the author's use of garlic practically as a cure-all. The use of garlic plasters for warts and corns (they work within two weeks) beggars the imagination.

Keith Vincent Smith, the author of *The Illustrated Earth Garden Herbal* (Elm Tree Books/Hamish Hamilton: London; £4.95) is an Australian journalist turned self-sufficiency gardener and writer. His book, described as a herbal companion, is an historical account by various ancient and fairly modern writers, of forty herbs, their "virtues" and uses, with recipes. This is an attractive work, of no great practical use, but obviously compiled with knowledge and affection for the subject. There are a few small errors — the genus *Tropaeolum*, for example, is a member of the *Tropaeolaceae* not *Cruciferae*.

The Encyclopaedia of Herbs and Herbalism, edited by Malcolm Stuart, (Orbis: London; £12.50) is disappointing. It is a pleasure to look at, but tries to cover too wide a field — not possible in the space available. There are too many illustrations — not all relevant — and some duplication of information. The quick gallop through the plant kingdom could have been omitted, as could that through the human body. The food recipes too are unnecessary. The main alphabetical list of herbal plants is well done but there is not enough general emphasis on the care needed in identifying and using such plants. This is the most ambitious of the four books under review, but the least successful.

Nature's jewels

YET more to add to the spate of books attempting to satisfy what publishers have found to be a very rewarding money-spinning exercise these days. Fungi have now come of age, and mushroom and toadstool books are now respectable enough to sit on the book-shelves along with those on flowering plants. It is as if the public in all walks of life have suddenly found the lost chord and whether the books deal purely with collecting and looking at fungi or eating them, or some kind of mixture of both people's appetites are apparently insatiable. Hopefully in the future the public will become more discerning as many of those illustrated texts now available are misleading.

It is refreshing that the present publications under review form a considerably better trio. Each is very different in its approach although inevitably they cover much common ground. There is still the need for a good book on mushrooms and toadstools that bridges the gap between the coffee-table approach and the advanced treatise although these present books partially fill that gap.

Geoffrey Kibby's contribution, *Mushrooms and Toadstools: A Field Guide* (Oxford University Press: Oxford; Hardback £7.95, paperback £4.95) consists of fifty pages of introduction, text, the major part of which is a key, and glossary, and two hundred pages of descriptive data accompanying illustrations. The illustrations are all from original water-colours (by Sean Milne) and seem to have been accurately taken from nature; the colour reproduction has been fairly faithful although the species depicted have a somewhat more lustrous appearance than when seen in the field. The abbreviated descriptions are from Kibby's field experience and so have some credibility. Over four hundred larger fungi are depicted, some of which are rare in Britain and are illustrated for the first time in a British field-guide. The key (with novel colour-coding) introduces the reader to the up-to-date classification. Usage by the uninitiated will only show how useful this approach is over more conventional keys.

E. Soothill and A. Fairhurst's *The New Field Guide to Fungi* (Michael Joseph: London; £7.50), is from the illustrative point of view the other side of the coin; the text by Fairhurst being supported by 252 coloured photographs by Soothill. Some of the latter seem to have been rather poorly reproduced, and some of the subjects have been partially burnt out by the flash technique used. Although the author has field experience, the descriptions in the majority of cases are taken from other field guides or monographic treatments, especially the microscopic data; and some unfortunately are incorrectly determined, for example, *Lepiota sistrata* and *Mycena pura*. The format is so very open that a lot of valuable space is wasted, and by using the same size of photograph, whether tree or minute fruiting body, it is difficult to judge size. In order to appeal to a larger audience some microscopic fungi are included as well as a spattering of North American species, for example, *Polyozellus multiplex*. Both groups could have advantageoulsy been left out, as their inclusion, especially the New World species, detracts from the workability of the key which somewhere in its production has gained the wrong numerals (page 24 read 18 for 17; page 26 read 57 for second 37). The introducing text is quite short with an accompanying glossary and poor line-drawings; two indices are included. The

book does not stand up to its dust-jacket statements suggesting that photographs are greatly superior to coloured paintings, as comparison with Kibby's book will soon show.

The Encyclopaedia of Mushrooms, edited by Colin Dickinson and John Lucas (Orbis: London, £9.95), is an interesting mixture of coffee-table style and scientific approach, and contains a mine of information as one might expect from the title. It needs several readings before the full extent of the details, from eating to electron microscopy, and chemistry to ecology, can be appreciated. The text of 280 pages is largely given over to descriptions with an unfortunate mixture of photographs and often appalling coloured illustrations some of which do not even resemble the fungi they are said to depict. The photographs gleaned from various sources are as might be expected of varying quality depending on the photographers and their wide spectrum of techniques. Many of the photographs are of species which have never been seen in a British publication before and so it is refreshing to get away from the same 'old' photographs of fungi, often misidentified, that one sees in the numerous books now available. As in Soothill and Fairhurst the descriptions are short; many are taken from the literature, as again they do not tie-up with the illustrations and therefore the field collections. Over five hundred larger fungi are illustrated with four hundred and thirty by photographs; unfortunately there are some mistakes, for example, *Mycena pura* has become *Laccaria amethystea,* and so on.

The introduction is a good account of the fungi and makes easy reading for the interested student. It is supported by very well chosen illustrations, and the ecological approach of many sections is admirable. Dickinson and Lucas obviously call on their joint teaching experiences, as they have brought together many of those interesting biological phenomena exhibited by fungi with which the layman is unfamiliar. As the dust-cover says, the *Encyclopaedia* is a combination of field guide, natural history encyclopaedia and cookery book. Indeed it is, Dickinson calling on his own culinary interests for the last.

Each book is well bound and on good quality paper; the printing is clear. Some mis-spelling of latin names is unfortunately inevitable and Soothill and Fairhurst's contribution is worst for this — even the dust-cover has one!

Whereas Kibby's contributions could be tucked into a 'poacher's pocket' and taken into the field; Soothill and Fairhurst's book is an awkward size; and Dickinson and Lucas' production was obviously designed for use in the home and library.

Roy Watling

Roy Watling is a Principal Scientific Officer and Senior Mycologist at the Royal Botanic Garden, Edinburgh, UK.

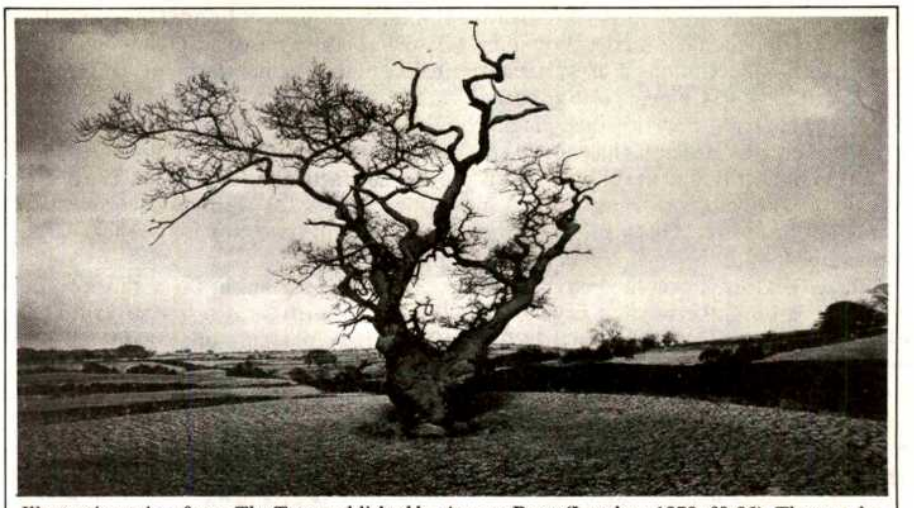

Illustration taken from *The Tree*, published by Aurum Press (London, 1979; £9.95). The text, by novelist John Fowles, accompanies some beautiful photographs by Frank Horvat. Fowles "explains the impact of nature on his own life, and warns urban 'civilized' man of the deeper and more subtle dangers that attend his traditional rejection of the wild.".

Arboreal devastation

After the Elm, edited by B. Clouston and K. Stansfield (Heinemann: London; £7.50) is described as both a requiem for the elm and a guide to the future care and improvement of the countryside. The first chapter, by Brian Clouston, describes the history of the elm in Britain with an emphasis on its role in the landscape. Reference is made to the works of John Evelyn and Gilpin, and there are quotations from Tennyson, Thomas Hood and Herbert Read. My only criticism is that the author persists in describing the wych elm (*Ulmus glabra*) as an introduced species, while as Eddie Kemp makes clear in the next chapter "The Plantsman's Elm", it is unquestionably native. Kemp himself wisely avoids becoming embroiled in controversies over elm taxonomy and presents a straightforward description of the principal types of elm to be found in Britain. Many of the photographs illustrating the trees are, however, disappointingly dull.

Kathy Stansfield's description of "Elm in the Service of Man" overlaps somewhat with the content of the first chapter, but also describes the use of elm wood in the construction of carts, pumps, furniture and boats. Then follow two useful chapters on the biology of Dutch elm disease (D. A. Burdekin) and on the impact that the disease has had on our elm populations (Peter Jones). While appropriate reference is made to methods of disease control, I would have liked to have seen some allusion to the important tree populations which have so far been preserved by control programmes. The Huntingdon elms of Hove park and the magnificent English elm around the Brighton pavilion deserve to be made the object of pilgrimage

The last third of the book is devoted to a discussion on tree planting. There are cogent criticisms of some current fashions — for example, that of planting in field corners — and useful comments on the choice of species. Thus the authors point out that the dark cypresses suitable to Italy create in Britain an effect of "gloomy walks and green-slimed stonework". There is some speculation on the extent to which the current enthusiasm for wood-burning stoves could lead to a renewed interest in coppicing as a system of woodland management, and also a welcome emphasis on the necessity for the adequate maintenance of newly planted trees. In summary, although less visually exciting than Gerald Wilkinson's *Epitaph for the Elm* (Hutchinson: London, 1978; Arrow paperback 1979; £4.95; for review, see *Nature,* **276**, 641; 1978) this is a more satisfactory book. A proportion of the royalties will go to the Tree Council for the National Tree Fund.

Robert lamb's *World without Trees* (Wildwood House: London; £4.95) is an anguished response to the devastation caused by Dutch elm disease, and there are sections on the elm, on the infection process, and on possible control measures. Interleaved with these are other chapters dealing with huge topics such as the destruction of the tropical rain forests, and the world-wide consumption of wood and wood products. Mr Lamb's racy style is often exhilarating and he has made a commendable attempt to describe the complex story of the disease cycle and the host's response in non-technical language. Sometimes, however, his intoxication with words carries him away: "fungal livestock, usually in the form of spores, may now become smeared into the notch by the carrier beetles jockeying for mouth-holes on the sap-rich wood".

More seriously, a lack of authority pervades the whole text. To take one tiny example he describes tyloses as "loops"; presumably because he has only thought of

them in two dimensions. A few pages later he states that the vertical furrows in the bark of elms "serve to prevent water-logging of the trunk by channelling off storm water". One wonders how smooth-barked trees like beech manage to survive at all! He speculates wildly on the subject of plant pathology. For example, he suggests that the ice age may have altered the course of evolution "by way of wholesale disease epidemics long after the climate itself had stabilised". The current deforestation by man is therefore seen as "a speeding-up of a natural process which would happen even if humans did not exist". Although one shares his concern over the way in which the world is using its forest reserve, the chapters on this topic fit incongruously into the framework of the book. I doubt if anyone can read it without feeling both breathless and confused.

John N. Gibbs

John N. Gibbs is a Pathologist at the Forestry Commission Research Station, Farnham, UK.

Botanical enthusiasm

SOME books are written to entertain and others to educate. Many books fail to achieve either aim, and a few manage to perform both functions. Naturally, the kind of book which *Nature* selects for review tends to be of the informative type, but even within these one may seek hopefully for a glimmer of aesthetic appeal lurking between scholarly brown covers. The collection of botanical publications reviewed here happily departs from the general run of scientific tomes dissected in these columns and consist largely of books for the amateur, the student or the enthusiast (the three are not necessarily coincident).

In the area of field guides especially, publishers undertake the task of conveying information to a non-technical audience in an accurate yet attractive and pleasing way. Five of the books here may be placed within this group and of them the most novel is *The Audubon Society Field Guide to North American Wildflowers: Eastern Region* by W.A. Niering and N.C. Olmstead (Knopf: New York; $9.95). This book is novel in a number of respects; first in its format which is small, if fat (almost a genuine pocket book), and its flexible plastic binding. It is evidently designed for hard wear in the field. Second it has a thumb tab on the pages of illustrations which indicates the colour and form of the flowers or inflorescences featured on that spread. Illustrations are arranged primarily on grounds of colour and then upon such characters as symmetry, or its lack, in individual flowers and their arrangement approach to the difficult task of leading the user to a group of species which he may compare with the unknown specimen.

There are, however, many criticisms which can be levelled at this approach. It departs from any strictly taxonomic basis for identification. All but the purist would find this forgivable as long as the characters used eventually permit accurate identification. In this case there are certain problems in obtaining this end. The illustrations, which provide the basis for identification, are colour photographs; however good these may be, it is impossible to portray all those features of the plant (growth habit, basal and stem leaves, inflorescence and flower structure, and fruit) which could have been more effectively represented by art work. A second criticism concerns the separation of the text from the illustrations. The text is full, informative and written in an informal style; it also refers to many species which are not illustrated. The general coverage (658 species) is only half that of Peterson and McKenny's *Field Guide to Wildflowers* (Houghton Mifflin: Boston; 1968) which remains the best available field guide for the north-eastern United States.

E.N. Kozloff's book, *Plants and Animals of the Pacific Northwest* (University of Washington Press: Seattle and London; paperback £6.30), undertakes the gargantuan task of providing an introduction to the entire natural biota of an area which approaches 80,000 square miles. Obviously the book cannot attempt a comprehensive coverage and it concentrates upon plants (including some bryophytes, lichens and fungi), vertebrate animals (apart from birds) and some invertebrate groups, such as molluscs. The text descriptions are lucid and contain an enthusiasm and casual detail which tell of the author's evident first-hand experience in the field. It is extensively illustrated by colour photographs which are generally of a higher quality than those in the Audubon guide. The coverage is very selective, but it succeeds in conveying considerable quantities of information in a pleasing and attractive manner. It must be highly valued by naturalists in that part of America.

The Oxford Book of New Zealand Plants (Oxford University Press: Oxford; £32.50) by L.B. Moore and J.B. Irwin also attempts a wide botanical coverage, from diatoms to palms. The format follows the familiar pattern of preceding Oxford guides with facing pages of text and plates. It is a very welcome book in that so little is available in the way of illustrated guides to New Zealand plants; and the artwork is both accurate and pleasing. Representatives are selected from major families of plants found in the Islands and are illustrated in considerable detail, floral sections often being included. It is sad that the bulk of the plates are two-tone as the coloured illustrations are quite superb and the book succeeds in being both entertaining and informative . Although dealing with a flora from the opposite side of the earth, this work should appeal to botanists and horticulturalists in Europe also, for some genera, such as *Acaena* are known as wool aliens and are now established immigrants, whereas others, such as *Hebe* are important decorative genera.

Blandford Press (Poole, UK) have made a brave attempt to fill the great monocot gap and have issued an illustrated guide to *Grasses, Sedges and Rushes in Colour* (£3.95) by M.S. Christiansen. This group of plants is sadly neglected among the current field guides, but I rather doubt whether this particular book will provide what is needed for the uninitiated to identify accurately these tricky plants. C.E. Hubbard's *Grasses* (Pelican, first published 1954) and A.C. Jermy and T.G. Tutin's *British Sedges* (Botanical Society of the British Isles, 1968) are far superior in that they provide keys and in that the illustrations are detailed and accurate. Colour is of little importance for the portrayal of these groups but as distinction often involves details of floral or fruit structure or, in the case of grasses, certain vegetative details, such as the ligule, these need to be clearly visible in the illustrations. In the Blandford paintings one cannot see the hairy ligule of *Sieglingia,* nor the prominent awn in *Holcus mollis* which helps differentiate it from *H. lanatus.* The attempt by the artists to exaggerate the

VOYAGER I

Enclose a cheque made payable to Nature. Price per copy (post paid): UK £1.20; USA & Can. US $3.50 (surface), US $5.00 (air); Rest of World £1.50 (surface), £2.00 (air).

Circle No. 34 on Reader Enquiry Card.

differences in hair distribution within these two species is not at all successful. Perhaps there is a need for a good field guide to these groups which is less formal and has more popular appeal than the two works mentioned above, but this is not it. When will an intrepid publisher move into bryophytes and lichens, I wonder? The *Oxford Book of Flowerless Plants* (Oxford University Press) has taken a step in this direction, but much remains to be done.

The Audubon Society of the United States has into the coffee-table market with its *Book of Wildflowers* (Harry N. Abrams: New York) by L. Line and W.H. Hodge. This is a large book which combines bigger, better colour photographs (five frontispieces gradually focusing in on a single *Eschscholtzia* bloom 30 cm in diameter), with a blotting paper text, and large print evidently designed for those myopic botanists who get past the frontispieces. As an example of botanical photographic art, the pictures in this book would be very difficult to beat. Every possible photographic technique is used to enhance the glamour of the angiosperm's reproductive structures, which is a perfectly good reason for publishing this book. The text is arranged by habitats, is casual and informal in style, and is reasonably informative. It evidently seeks to convey something of the excitement and appeal of field biology, which is a laudable aim.

Two books which appear to be aiming for the conveyance of information rather than the stimulation of gasps of rapture among their readers are those dealing with the description of flowering plant families. P.H. Davis and J. Cullen have issued a second edition of their key, *Identification of Flowering Plant Families* (Cambridge University Press: hardback £6, paperback £1.95) found wild and cultivated in north-temperate regions — first published by Oliver and Boyd in 1965. Although it is not a subject which any longer receives great prominence in most undergraduate botany courses, classical taxonomy still forms the basis of much field ecology and its neglet is resulting in a generation of students trained in concepts and lacking the skills of field identification, and sometimes even observation. It would be a useful exercise to encourage students to work through a key like this at their leisure, both in natural habitats and in gardens. It should prove a useful supplement to V.H. Heywood's *Flowering Plants of the World* (Oxford University Press, 1978).

R. Headstrom's *Families of Flowering Plants* (Thomas Yoseloff: London; £12.50) lacks the key of Davis and Cullen's book and falls very far short of Heywood's book in its content and presentation. The book contains a discussion of 212 families, including some gymnosperms arranged in alphabetical order of English names, and deals with each family by selecting species of interest and describing their structure and traditional uses. This is not a book for anyone interested in taxonomy, evolution, biogeography, ecology or morphology.

Is it reasonable that one region of botany has been totally ignored by the entire scientific community simply because of its non-existence? This is a question framed by L. Lionni in his book *Parallel Botany* (Wildwood House: London; Paperback £3.95). Why has it not been reported in *Nature* that the flowers of *Anaclea taludensis* vaporise instantly on contact with any object which is not part of their normal ecological environment (see Kamicochi, *Proc. Int. Bot. Congr.* Tsuchimachi, 1974)? Is this indeed a demonstration of Leibschmidt's law that "for every immobility in time there is a corresponding immobility in space"? If you find this kind of question intriguing, then this is the book for you, as a long as you are contented with questions and do not seek answers. A book for the Botany Common Room rather than the library; definitely designed to entertain rather than to inform.

The Story of England's Flora (Kestrel: London; £6.95) by E. Hyams is an attractively produced and lavishly illustrated book. The text leads us on a brief and rather superficial tour of palaeobotany in which the information is reasonably accurate but is so patently second or third hand that it lacks conviction. It proceeds to describe trees, shrubs and herbs (both native and introduced) which have an interest for man. The line drawings are inaccurate (hirsute and crenate *Fagus* leaves), inappropriate (Lombardy poplar in a text piece on the Tertiary) and misleading (a woodland referred to as beech on chalk in which the mature trees are oak and which is almost certainly upon a clay with flints substrate). The book is in part redeemed by some quaint anecdotes concerning the introduction, origin and the breeding of some domstic plants. Another sadly superficial book which deals with a fascinating subject is *Plants that Eat Animals* (Nelson: Nashville and New York) by J.H. Prince. It is a survey of insectivorous plants, their structure, mode of action and physiology. Even though it is intended as a popular book, in the sense that it appeals to the general public, it could have been so greatly improved if the results of modern research had been included. How can one write such a book without including scanning electron micrographs of the glands of *Pinguicula* and without any detailed discussion of the transfer of 'nervous' impulses in plants? Instead we have a simplistic essay illustrated by crude line drawings.

Any review of botany books which attempt to combine education and entertainment would be incomplete without reference to David Bellamy. Two books have emerged on to the market following his *Botanic Man* television series. The book with the same title as the series (Hamlyn: London; £6.50) is a didactic summary of the ideas presented over the television screens. It contains many double-spread colour photographs (a 40 cm diameter bromeliad competes well with the Audubon spectacular in the battle to blow the mind) but Bellamy puts these diversions to far better use by punching home attractively presented information in the intervening pages. He seems to be aiming for the advanced school audience, but how different his approach from Lawson's *Textbook of Botany!* The range of concepts he covers is impressive (from the Periodic Table, through DNA, nutrient cycling at a global and ecosystem level, vegetation zones in relation to climate, plant productivity, even to island biogeographic theory). The text, like David Bellamy himself, is forceful, concise and energetic; it must be read with a South London accent. But above all, this is a living, enthusiastic book which does not avoid or skim lightly over awkward questions; it meets them head on.

A second booklet, *Botanic Action* (Hutchinson: London; hardback £4.95, paperback £3.95) is literally an activity book for children, giving them ideas on how to design simple experiments at home, such as growing seeds in used tea bags to look for mineral deficiencies. Or, how about making paper from stinging netle fibres, or leaf skeletons, or plant based dyes, or dandelion tea? If you have active children interested in their surroundings and if you are not too worried about the state of the carpets, this is just the book to give them for Christmas. Then is the time to judge whether a book can be both informative and entertaining.

Peter D. Moore

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences at King's College, University of London, UK.

Guide to alpine flowers

The Alpine Flowers of Britain and Europe. By C. Grey-Wilson. Pp.384. (Collins: London, 1979.) Hardback £5.95; paperback £4.50.

THIS is a most useful field guide to the flowers of the hills and mountains of Britain and the continent. It spans from Cape North to the Abruzzi and from Southern Yugoslavia to Ireland. The colour illustrations are from the excellent paintings of Marjorie Blamey. The geographical area covered is about the same as in that most successful book of 1967 by Anthony Huxley *Mountain Flowers* (Blandford: Poole, UK); but the lower altitudinal limit of 1000 metres adopted as a criterion for inclusion, has increased the

number of species illustrated, though most of the additions are really not "alpines". Over the wide range in latitude – from 42° to 71° N –spanned by this book the tree limit descends from some 2300 metres on the Alps to near sea level in Northern Scandinavia. Tree limit is usually taken as the lower boundary of alpine vegetation. It is ecologically much more significant than an arbitrarily fixed altitude, meaningless over such a huge latitudinal span. This is no criticism of the content, only of the title of this book. Anyhow, many of the readers will botanise from foothills to high mountains; for them this field guide caters well, in spite of its somewhat disconcerting title.

There are a number of good features. Text and illustrations are face to face. The description of each species is appropriate and succinct, and it helps to have the diagnostic features in italics. Two keys based on drawings of flower shapes and one, for trees, based on leaf shapes help with preliminary identification. A number of plates give comparative drawings of one or other important diagnostic character in the case of the species of a few difficult genera or families: for instance, calices for the genus *Dianthus*, fruits for some umbellifers, and so on. The illustrated glossary is very clear.

Three minor criticisms: the use of English names for families; the invention of an English name, by translation from the latin binomial, for species which do not have one; and the omission of the author's name after the botanical name. We should not fall into the deplorable habits of American field guides. This guide is dedicated to the Alpine Garden Society which celebrates its Golden Jubilee this year. It will make a most useful companion, as a pocket field flora, to the book *Mountain Flower Holidays in Europe*, just published by that Society. I am sure all members, and those of the sister Scottish Rock Garden Club, will need, and make good use of this guide.

Orchid growing

Orchids in Colour. By B. and W. Rittershausen. Pp.192. (Blandford: Poole, Dorset, UK, 1979.) £4,95.

THE attraction of this book by two well-known orchid-growers lies principally in Robin Fletcher's beautiful photographs, the authorship of which, despite the book's title, is not even acknowledged on the jacket. Over one hundred different species or hybrids are illustrated, sufficient to give an idea of the astonishing range of form and colour of these plants, whose increasing popularity is easily understood.

The introductory text comprises general remarks on the Orchidaceae, followed by separate sections dealing with the history and cultivation of the principal groups now grown. This first part suffers from an occasional tendency to become romantic at the expense of botanical accuracy, with such remarks as those with regard to nourishment (which "the orchid has learnt largely to do without"); the "meagre needs" of epiphytes "are totally satisfied by the moisutre of the atmosphere". Fortunately in the separate sections that follow, quite full notes on various aspects of orchit culture are given, particularly as regards temperature and humidity (both of which are critical to successful orchid growing), the use of composts, and the timing of repotting and other cultural practices. Under modern centrally heated conditions, many orchids can be grown in a normal living room, and the suitability of various groups is duly noted. Brief notes on pests and diseases are also included in these sections of the book.

Apart from the breeding of new hybrids, large numbers of which are created every season, modern orchid propagation relies for many groups on "meristemming", the excision and subsequent culture of the growing tip of a shoot; and it would have been useful to include a more detailed description of this practice. There is also virtually no account of the genetics of the extremely interesting and complex nature of multigeneric hybridisation.

Detailed notes (facing each plate) are given on the history and culture of the actual varieties illustrated, and these also deal with related species or hybrids. As a whole, however, the text could do with considerable editing: besides a tendency to be repetitious and thus sometimes confusing, it is at times so ungrammatical as to be obscure and irritating for the reader to a degree that should not occur in a book of this style and authority. One point in its favour is the small format of a volume that one might have expected to see published as a much larger 'coffee-table' book.

Peter Collins

Peter Collins is a freelance science writer who has been studying the orchids of Europe for more than 25 years.

Man's use of dry lands

Dry Lands: Man and Plants. By R. and M. Adams and A. and A. Willens. Pp.152. (Architectural Press: London, 1979.) £12.95.

This volume is written by two landscape architects, a horticulturalist and an agriculturalist, who are concerned to put their expertise to use in the careful management of dryland ecosystems. As a background to this aim the categories of arid land and their special characteristics are represented in some detail. Causes of aridity are discussed, and methods of supplying an index of its severity presented. This is followed by a survey of Northern and Southern Hemisphere desert zones; desert morphology and soils are presented next and desert vegetation types described, including methods of adaptation by plants to arid conditions. This leads on naturally to plant selection for arid regions and the way in which man may manage and modify desert ecosystems. Subsequently, survey and planning methods are expanded, and design and implementation procedures are outlined.

To deal in detail with such an extensive remit would be difficult and in seeking ways to overcome these difficulties the authors have been both inventive and shallow in turn. Overall, the book is attractive in both its presentation and treatment; it follows through from ecological considerations to methods of developing areas agriculturally, for forestry and horticultural purposes, and then to urban landscaping and the development of a coastal site — marina, shops, hotels, airport hotels and gardens. The designs for urban spaces look attractive but the nearest I have experienced to them, in practice, is in Venezuela rather than in the arid zones of Africa or the Middle East. In the course of developing such plans a site survey checklist is presented. This includes hydrological features, geology, topography, soil characteristics, climate, and ecological components. Enough detail is given of the necessity to consider each feature in turn but usually this would not allow a basic understanding of the way in which the various factors operate or how they interact. Where attempts are made to give a basic understanding (as where features of C_3, C_4 and CAM photosynthesis are explained) these can be confused in their presentation and attribute findings to authors who have merely carried along investigations initiated decades previously by other workers.

As an interesting excursion into the application of ecological expertise to planning and land management in difficult situations, this book can be recommended. The work is a useful guide for the ecologist seeking to apply his knowledge. For the planner or landscape architect, seeking the scientific basis for his art as applied to the arid zone, it falls short of a *vade-mecum*.

M.J. Chadwick

M.J. Chadwick is Senior Lecturer in Ecology at the University of York, UK.

Nature Vol. 282 6 December 1979

Fascination for fossils

FIVE recently published books on various aspects of prehistoric life and the evolution of the vertebrates are reviewed here. All are intended to help the layman realise the fascination that fossil life might hold for him.

The Hamlyn Nature Guide to Fossils (Hamlyn: London; £1.95), by Richard Moody, begins with a brief introductory section covering geological time, fossilisation and fossil collection, preparation and curation. There is then a simple key to the identification of fossil material down to phylum or class level. The bulk of the book consists of attractively presented colour photographs of some 200 fossils, mostly identified to generic level accompanied by a description and a brief statement of range, both stratigraphical and geographical. Most of the fossils are of common occurrence, though one or two are to be considered rarities; many have world-wide distribution.

The generic identifications are virtually all correct, and the balance of different groups is nicely judged. The various invertebrate fossil groups are treated in turn, followed by a few vertebrates, trace fossils (strangely conodonts and *Serpula* appear under this latter heading), and plants.

My main criticism concerns the photographs. Several are larger than the frame size allows so that parts of the fossil are missing beyond the margins of the plate. Others are presented in rather unconventional orientations. In other cases more than one view is needed and this could have been easily achieved within the frame-size, as the example of *Leptaena* shows. However, apart from a few ill-preserved specimens and a handful of poorly lit ones, the photographs are of high standard and there is never any doubt about what is depicted.

Although there are labelled diagrams to illustrate morphology, I felt sometimes that the descriptions became a little too technical for the amateur fossil collector, to whom the book is directed. He will no doubt welcome it as an attractive and useful addition to his library. The book would fit into a good-sized pocket and could be used in the field.

Fossils (Collins: London; £3.50), by David Dineley, aims to fill a gap which exists in the palaeontological literature; it is thus neither a palaeontology textbook, nor a field guide to fossil identification. The author has produced a book which presents, in a very readable way, the subject of palaeontology to the layman.

After brief introductory sections on sedimentary processes, geological time and evolution of life, there follows a chapter on plants which, in an effort to be comprehensive, perhaps errs too much towards the rarely fossilised non-vascular plants. Treatment of animal fossils follows mode of life, with plankton and nekton being described before benthos. Terrestrial life then follows, leading on naturally to vertebrates and vertebrate evolution.

Having thus covered the major groups of organisms, the author then looks briefly at fossil communities. Techniques of fossil collecting are prefaced by a code for fieldwork and several conservation-minded caveats. The concluding section suggests areas in Britain where fossils may be sought, with further reading for each area discussed. There is a useful list of books for those interested in going into the subject more deeply.

The book is illustrated with numerous line drawings and sixteen black-and-white plates. Two of the latter were badly blurred in my review copy; I suspect this may be a unique fault to my copy but would-be purchasers should perhaps check the plates before buying. There are minor errors in some plate captions.

Professor Dineley's approach, together with his easy-to-read chatty style should win him applause from those who have been (or are about to be) seduced by the fascination of fossils.

Prehistoric Animals and Plants (Hamlyn: London; £2.95), though nominally by Josef Benes, must be considered essentially as a means of displaying reproductions of prehistoric life as seen by Zdenek Burian. After an introductory five pages of text on the origins of life and on invertebrates, there follows some three dozen more pages of text devoted almost exclusively to vertebrates.

After this preamble we are into the bulk of the book, which consists of coloured pictures of animals or faunas as they may have appeared, accompanied by a descriptive text which has been well translated from the original Czechoslovakian. The plates are reproductions of original paintings by Zdenek Burian and are a tribute to his skill in convincingly reconstructing the animals in their environments.

Although this book is up to date in some respects (it contains, for instance a Precambrian reconstruction based on the Ediacara fauna), in other cases it suffers from being behind the times — as for instance in the pictures of dinosaurs which are based on the "giant lizard" concept of dinosaur physiology. *Brachiosaurus,* for example, is relegated to a watery life, as it has been so often in the past. It is to be regretted that the book is so heavily vertebrate oriented particularly because the few reconstructions of invertebrates are so successful.

The standard of the pictures varies, but it is not clear whether this is entirely due to faulty reproduction; some colours in a few pictures are rather garish, a few images appear to be out of focus, and some pictures were originally painted on a rather coarse canvas to the detriment, sometimes, of detail in the reproduction. The work must represent the output of the artist over a considerable period so that differences in style are not unexpected.

It is not clear to whom this book is directed, but at the remarkable price of £2.95 for a hardback book with over 300 pages and more than 130 colour pictures, it should find a ready market in anyone interested in realistic reconstructions of extinct vertebrates.

The Evolution of the Mammals (Peter Lowe: London; £4.50), by L.B. Halstead, begins with a definition of what constitutes a mammal, and then explores briefly and succinctly geological time, evolution and the fossil record, the origin of life, and then goes into more detail on vertebrate evolution. Thus by the time that mammals are first discussed in detail, the reader should be fully aware of their relationship to other vertebrate groups and their range through geological time.

The Mesozoic mammals are dealt with rather sketchily, but there is a fuller treatment of Cainozoic mammals, initially system by system, in which differences between successive faunas are spelt out clearly in the text and by superb coloured illustrations; some of these illustrate different genera of particular mammalian groups and others, reconstructions of mammalian faunas of different ages in their supposed environments. The pictures are very successfully executed and the considerable impact of this large-format book owes much to them.

There are sections on the evolution of man, on the different faunas to be found in the main continental areas and even predictions on what the future holds for the mammalian class.

The whole book is clearly written, interestingly presented, and succeeds in telling the history of mammals through geological time in a most absorbing way. Although the key words for the British Library Catalogue are listed as "Mammals — Evolution — Juvenile literature", I venture to suggest that most parents who buy this book for their offspring will find it fascinating reading for themselves.

The subtitle of *Archosauria,* by J.C. McLoughlin (Allen Lane: London; £4.50) — *A New Look at the Old Dinosaur* — also appears in large print on the dust cover and will no doubt cause confusion with Alan Charig's new book *A New Look at the Dinosaurs* (Heinemann: London, 1979). However, in content John McLoughlin's book is much closer to Adrian Desmond's *The Hot-Blooded Dinosaurs* (Blond and Briggs: London, 1975).

A zoologist by profession (as are many vertebrate palaeontologists), the author is entirely sold on the idea that dinosaurs were endothermic (warm-blooded) animals, and the book considers the Archosaurs as a class of vertebrates (following the line first proposed by Bakker and Galton).

Each group of archosaurs is discussed and their functional morphology in the

light of an endothermic physiology re-interpreted. The text is well written, though the British publishers have apparently reprinted the American edition, as American spellings persist. The author has provided his own illustrations and succeeded remarkably in selling his argument by managing to give an intelligent and alert expression to the faces of the long-thought slothful dinosaurs. The arguments are put over clearly and persuasively, but the author too rarely considers alternative viewpoints to his own. I found his attitude to classical dinosaur reconstructions somewhat patronising, and felt that the criticisms of earlier workers were not entirely justified. Despite his biased view, the author has produced a book which is certainly stimulating, very readable and attractively presented, and which will appeal to anyone with an interest in dinosaurs, whatever their background.

John C. W. Cope is Senior Lecturer in Geology at University College, Swansea, UK.

In the hands of the rockhounds

MINERALOGY is increasingly in the hands of the rockhounds. Short courses in gemology and the lapidary arts are over-subscribed and will hopefully lead on to a much wider public interest in the earth sciences in general. Sadly, one consequence is that well-known mineral localities, and some which once were near-secret, are picked over and almost barren. Disused workings are being closed for safety reasons and recent legislation all but bans collectors from active mines. For all except the mundane, many collectors are forced to buy imported specimens and professional collecting has become highly profitable. It is not unknown for *bona fide* scientific collectors or the casual amateur to be literally driven off outcrops by well equipped and frenzied dealers or their suppliers. In this context, the publication of three new books aimed at the amateur can be received with some misgivings. Not one of them pays any attention to the pressure on sites nor to conservation practices. That being said, professional geologists should attempt to encourage wider interest and activity in this field as a route to popularising earth sciences. But to what extent do the new books contribute to this aim?

The Hamlyn Nature Guide to Minerals by Andrew Clark (Hamlyn: London and New York; £1.95) is a thin book, in all respects. it claims to be a practical identification guide but its brief introduction to mineral properties is too dry for the beginner. Its 436 colour photographs are pretty enough, but the brief mineral descriptions are not arranged in a suitable format for easy identification. The order is the conventional composition/atomic structure classification, which is no guide to minerals' immediate appearance. No information about localities is given but there are very brief notes on geological setting, which will certainly not aid the non-geologist to find good specimens. Perhaps this is a book for the pure conservationist.

The Audubon Society Field Guide to North American Rocks and Minerals by Charles W. Chesterman (Knopf; New York; $9.95) is in another class. It contains 794 magnificent colour photographs and is virtually a self-contained introduction to geology through its more aesthetic products. The book begins with a simple but comprehensive account of the diagostic properties of minerals. The ordering of photographs does not match that in the identification tables or the extended mineral by mineral descriptions — the photographs being arranged by colour and form, the tables by colour and hardness. But this is only a minor irritation, albeit unecessary. The quality of specimens was a little daunting for this casual collector and perhaps for even more determined rockhounds. This reflects the use of tiny specimens or micromounts — forced on modern collectors by the self-induced dearth of 'mantle piece' specimens. Common rocks are well treated and sufficient space has been devoted to introducing the elements of the science, as well as the hobby, to make this book a notable contribution in the field and excellent value.

Rock and Mineral Collecting in Britain by Peter R. Rodgers (Faber and Faber: London, hardback £6.95, paperback £3.50) is a good text for absolute beginners and relates mineral occurrences to geological setting quite adequately. However, the simplification into igneous, sedimentary and metamorphic classes of deposits can be misleading at this elementary level, and arguably a better approach would have been regional descriptions of famous mineral sites. The localities listed seems impressive, but the reader soon finds those mentioned in the text very elusive. The most useful items are the mineral catalogue and the list of localities with grid references. There are glaring omissions among the localities and the list would have been better organised region by region with accompanying maps. Several famous British minerals, noteably mimetite, harmotome, torbanite and alstonite are in-explicably absent. The beginner will find this an encouraging little volume, but a little extra documentation might have found a ready demand among more experienced collectors.

Stephen A. Drury

Stephen A. Drury is Lecturer in the Department of Earth Sciences at the Open University, Milton Keynes, UK.

How to grow your own rubies

IF you want an excuse not to give your wife an opal for Christmas, you will find one in D. Elwell's book: *Man-Made Gemstones* (Ellis: Chichester, UK; Wiley & Halstead: New York; £15), both natural and synthetic opals are porous, and serious cracking can occur if they are immersed in warm soapy water.

Far better to give her a ruby — "Growing rubies by the flame fusion process in the garage is possible, but not recommended. We will therefore consider flux growth" . . . Dr Elwell goes on to give detailed instructions, but briefly you take a platinum crucible, mix lead fluoride with the oxides of lead, boron, aluminium and chromium, add a pinch of lanthanum oxide to improve crystal shape, put in the oven at 250°C for 24 hours, allow to cool slowly, and extract your crystals using nitric acid.

Unfortunately, your home-grown rubies, though real, will be "synthetic". This is an important qualification. Synthetic gemstones are identical, chemically and crystallographically speaking, to the real thing; but they are usually distinguishable from, and therefore less valuable than, natural gemstones. 'Imitation' or 'simulated' gems on the other hand resemble the real thing but are actually a different material; thus yttrium aluminium garnet (YAG) and cubic zirconia are both used as diamond simulants.

Opals do have their own fascination, as Elwell explains, even if you cannot yet grow your own. They are unique among gemstones in being an ordered array of silica crystallites, whose spacing leads to diffraction of visible light and hence to a captivating play of colours as the gem is moved. Most other gemstones are genuine crystals — an ordered array of atoms — and are transparent, whereas opal is opaque.

I certainly enjoyed reading Dr Elwell's book. Although ruby is the only crystal he gives a recipe for, he also describes the synthesis of sapphire, spinel, emerald, diamond and its simulants, and many other precious and semiprecious stones.

Gemology (Wiley-Interscience: New York and Chichester, UK; £13.50) by the

Professor Emeritus of Minerology at Harvard (C.S. Hurlbut) and the Curator Emeritus of Minerology at the Smithonion Institution (G.S. Switzer) is a self-confessed "textbook" aimed at gemology courses as well as at jewellers and collectors. As such it is less readable tha *Man-Made Gemstones*; but it is much better as a work of reference — as well as being bigger (in number of pages and page size) and cheaper.

The book covers origin and occurrence of gemstones, crystal chemistry and crystllography, physical and optical properties of gems, gemological instruments, synthesis of gems, imitation gems, cutting and polishing. The longest chapter, "Descriptive Gemology", tabulates all the important features and characteristics of the common gemstones (and some uncommon ones) with particular emphasis on how to tell whether the gem is natural, synthetic or imitation. There are also twelve full-page colour plates of superb quality.

These books are complementary, rather than being in direct competition; and both would make suitable presents for your favourite lapidary or jeweller, or for anyone with a scientific interest in gems and crystals. But if you can afford only one of them, *Gemology* is the bettery buy.

John Walker

John Walker was a Research Fellow at the Universities of Reading and Paris, studying the optical properties of diamond. He is currently a microprocessor consultant.

Everything you wanted to know about cancer but were afraid to ask

DISEASE has always haunted the human imagination. Leprosy, the black Death and other horrors have in turn stalked the misty frontiers of the collective unconscious. As the lethal epidemic diseases recede into history the archetypal phobias of Western Society are shifting their attention to cancer. One of civilisation's most awful self-inflicted wounds, cancer has become, like death itself, a taboo. In the third world the peasants flee to the hills when cholera strikes; in our affluent society there is nowhere to run to avoid what the late John Wayne called the big C. In the belief that fear can be abolished by knowledge (or rather, information) two recent books have been launched — from different directions and aimed at different audiences.

The Cancer Reference Book (Paddington: New York and London; £4.95), by P.M. Levitt and E.S. Gurabrick, is written by two American Professors of English using information provided by a small team of established cancer specialists. It is deliberately written in simple English, avoiding all technical language or complicated concepts. The style is light with quotations from Dylan Thomas, Robert Lowell *et al*, and it is rigorously honest. There is no obfuscation, no undue optimism. If a treatment does not work, the book says so. Reassurance is offered only when justified. It provides brief descriptions of the various forms of cancer and provides lists of questions and answers. The questions are real — the sort of questions asked by patients and their relatives. The information provided is strictly limited to topics of immediate relevance to patients with malignant disease and to the uninformed general public. Symptoms, treatments, prognosis and terminal care are well covered. The long section on widespread cancer and terminal care is very well presented and pays an envious tribute to the British hospice movement. Some aspects of the dialectic are (at present) peculiar to North America. Unproven treatment methods such as laetrile and the orgone box receive a lot of critical attention and furthermore the authors recommend that all men over 50 should have a rectal examination once a year. They also deal with "cancer insurance" in some detail, as in the USA 2 million such policies are sold every year. The cost of treatment for breast cancer can be as high as $100,000 per patient.

Assuming that the reader knows absolutely nothing, the book contains simple line drawings most of which are probably helpful. However, one picture of the mouth labelled "the mouth" seemed just a little superfluous. However, this volume cannot really be judged by doctors. It is for the general public and for patients. To assess its value I have just completed a small uncontrolled trial by inviting questions from patients, relatives and friends. Each and every question was answered, and answered well, although finding them by referring to the index was a little frustrating at times. *The Cancer Reference Book* contains, as advertised in its subtitle "Direct and clear answers to everyone's questions". It must therefore be judged a considerable success. Its honesty will I suspect upset some doctors more than their patients. It could make life a little difficult for those, who, with euphemisms and woolly reassurance, use deception as a form of therapy. *The Cancer Reference Book* could be a blow for patient's lib.

Cancer: the Outlaw Cell is an edited collection, by R.E. La Fond, of articles originally published in *Chemistry* and now dressed up and issued by the American Chemical Society (Washington DC; $15). It is a distinctly upmarket product. Written originally for chemists (no, not pharmacists) it now seems to be addressed to what I can only describe as "a BBC2 audience". Expensively produced and beautifully illustrated its approach is conventional but slick (witness the title). Clinically it is uninformative and contains little or nothing about what cancer is or what it does to people. It is essentially a basic primer in some current trends in cancer research, very basic in places. An introduction to cell chemistry, for example, takes less than a page and a half. There are, however, some excellent general essays. Dr Armin C. Braun's chapter on cancer as a problem in development will fascinate anyone with an O level in biology. There are also comprehensive chapters on chemical carcinogens, oncogenic viruses, the cell surface and the inevitable immunology.

A simple but concise essay on cancer chemotherapy by the Drs Burchenal highlights a central issue in contemporary cancer research. The logical approach to finding new drugs, they say, would be to find differences between normal and malignant cells and then exploit the difference. However, as this approach has been tried in the past and failed, it has been replaced almost totally by empirical drug screening, looking for anti-proliferative agents, agents which by definition, are bound to be toxic. To illustrate the current obsession with "multi-modality therapy" they provide an unfortunate analogy. The body, they say, is like a lawn, normal cells are grass and cancer cells are weeds. Surgery is therefore the equivalent of hand weeding, radiotherapy is a flamegun and chemotherapy is (or should be) a selective weedkiller. Stimulation of the immune response is the equivalent of stimulating the grass to choke the weeks. As they put it so succinctly, immunotherapy is fertiliser.

It is an optimistic book, the authors of each chapter arguing strongly for their own line of research and its potential value. It is an excellent bit of public relations for American cancer research; no room here for self-doubt, for the currently fashionable pessimism. As an introduction to cancer for the scientifically literate layman it could make a fascinating read.

G.A. Currie

G.A. Currie is Reader in Tumour Immunology at the Institute of Cancer Research, and Honorary Consultant Physician at the Royal Marsden Hospital, Sutton, UK.

• In the review of *Malignant Neglect* (see *Nature*, **282**, 166; 1979), the first sentence of the second paragraph should have read: "A normal metabolite, ammonia, is called (page 105) a "toxic organic vapor"."

Man's place in Nature

The Ancient Science of Geomancy: Man in Harmony with the Earth. By Nigel Pennick. Pp. 180. (Thames and Hudson: New York and London, 1979.) $16,95; £5,95.

FOR those who believe that a proper understanding of our world can come only through the application of the scientific method — by observation, hypothesis, prediction and test, leading to verification or otherwise — this book will read as mystical nonsense. For those who believe that there are other, less rigorous ways to the truth, who prefer a mystical to an archaeological or historical approach to the past and who are also attracted to the idea of a return to a technologically simple and harmonious human culture, it may well have considerable appeal. This conclusion is quickly reached by reading the Introduction in which the author's basic assumptions are clearly stated they are vast, irrational and of a nature that precludes almost any kind of constructive criticism.

> "The practice of geomancy, which may roughly be defined as the science of putting human habitats and activities into harmony with the visible and invisible world around us, was at one time universal, and vestiges of it remain in the landscape, architecture, ritual and folklore of almost all countries in the world. This remarkable series of correspondences between different cultures has been held to be evidence for a former world civilisation . . . These archetypal patterns . . . have produced the worldwide occurrence of outward form and inner purpose found in geomancy. Hence the seeking of cosmic power points on the surface of the Earth, special places where the mind can expand into new levels of consciousness . . ."

If one accepts these basic assumptions — a better phrase would be "this basic faith" — then all the rest follows. The book elaborates on the theme, describing a wide range of curious facts and phenomena as if their mere recounting is enough to prove the author's case. The Thoms' work on standing stones is inevitably brought in, as if this particular example of the refutation of the old simplistic idea of the steady progress of man from savagery to modern urban civilisation also proved the existence of a world-wide science in antiquity. Ley lines appear, as does dowsing; and holy wells, holy hills and geometrically designed buildings are thought of as places where the natural energies of the Earth were identified and tapped in ancient times. Proofs of the power of these energies — as of all aspects of geomancy — are invariably sought in unattributed and unverifiable reports of "evidence", as of an allegedly sacrificed animal removed from its burial place, of disasters following and ceasing with the return of the corpse to its tomb. Adverse criticism is exorcised in advance by allegations of bias and prejudice among professional scientists and scholars. The mind reels at the task — fortunately unnecessary — of analysing and assessing this mass of diverse and incoherent material. Probably it is best simply to regard the work as a compendium of bizarre and interesting phenomena and tales.

One general point, however, is worth making. The thread running through the book is that in early times (what archaeologists call the Palaeolithic, or hunting and food-gathering period) man lived in complete harmony with nature and that this harmony was later disrupted with the invention of agriculture. In a typical phrase, full of apparent meaning but defying close analysis, "settled life necessitated the enclosure of space, a stopping of the free flow of the spirit of the earth . . .". All signs of ancient skills and wisdom are interpreted in terms of early Man's knowledge and utilisation of the Earth forces assumed to exist behind such harmony. However, this "harmony" can also be interpreted quite unmystically in terms of the natural (that is, unconscious) selection of technologically primitive societies so that those survived which were best adapted to their environments. No alien spacemen, antediluvian Atlantean civilisations or practitioners of a world-wide geomantic science are needed — but a thorough knowledge of the available archaeological and historical evidence is.

This makes the point forcibly that, in the 120 years which have elapsed since the publication of *The Origin of Species*, the application of the theories of evolution and natural selection to the development of man and his societies has made too little headway. The second half of the Darwinian revolution is thus still incomplete and, as a result, a host of beliefs and dogmas based on assumptions about the special nature of *Homo sapiens*, and on his independences, of natural laws, continues to flourish. Until, in T.H. Huxley's phrase, "Man's place in nature" is properly and widely understood and accepted there will still be massive markets, even among educated people, for books of this kind in which the effects of natural selection are viewed anthropocentrically and attributed to primeval wisdom, or are explained by supernatural or extraterrestrial agencies.

Euan W. MacKie

Euan W. MacKie is at the Hunterian Museum, University of Glasgow, UK.

Glimpses of volcanoes

Volcanoes. By M.B. Lambert. Pp.64. (David and Charles: London and Newton Abbot, UK; University of Washington Press: Seattle, 1978.) £3.95; $10.95.

IT is amazing how little the author has managed to cram into this slim volume. The book runs to 64 pages, over half of which are devoted to pictures and diagrams, and it is divided into 10 principal sections, each of which consists of a few pages of text, some relevant pictures, a surprising amount of blank space and a vaguely volcanic snatch of verse. The sections cover fairly conventional topics such as "Major volcanic landforms", "Products of explosion", "Volcanoes in time and space", and so on. Unfortunately, the contents of the sections do not match up to their worthy titles. The section on "Volcanoes in time and space", for example, runs to only a few hundred words, about half of which are devoted to Canada.

It is difficult to see quite what kind of a book the author was aiming at. One could make a strong case for the publication of a good coffee-table book on volcanoes, but this one does not come anywhere near it, as although many of the photographs used are good, they are not numerous enough, not glossy enough, and not in colour. The book is also emphatically *not* a "simply yet thorough introduction to volcanoes", as the dust-jacket claims, but is instead a patchy, misleading digest of information on a subject which is inherently very popular among lay-readers.

Such readers are likely to fare badly from Lambert's book. What, for example, is the uninformed reader going to make of the 400 words on page 9, which includes a discussion of thermal gradients, upper mantle composition, partial melting and fractional crystallization? Not much, I suspect. The best that can be said about the text is that it is at least accurate for the most part, being derived from respectable sources to whom Lambert makes due acknowledgement. In many cases, however, Lambert's use of these sources is curiously ill considered. He quotes, for example, Macdonald's figure of 1,800,000 km^2 for the extent of the so-called 'Thuelan Plateau'. It is now generally accepted that it was never anything like this size, the various components having been widely separated by seafloor spreading. Macdonald even goes so far as to suggest this possibility, but Lambert ignores it.

Peter Francis

Peter Francis is a Lecturer in Earth Sciences at the Open University, Milton Keynes, UK.

Frozen Earth

The World of Ice: A Natural History of the Frozen Regions. Pp. 120. By B.S. John. (Orbis: London, 1979.) £5.95.

THIS attractively produced book would look well on any coffee-table and should arouse interest in the World's ice in all its varied mainifestations. Brian John has written a stimulating and, for the most part, basically sound account of the ice-covered or frozen regions of the Earth that assumes little acquaintance on the part of the reader with technical terms, whether geographical, glaciological or biological. (A glossary is included.) It is therefore a book for the interested layman, the general reader, and only superficially for the student, the scientist or the naturalist. It is illustrated by about 100 superb colour plates, some covering a page or double-page spread; the layout is spacious, the quality of production high and the price very reasonable.

The text is clearly written but, inevitably, compressed and simplified, so that the unwary or a reader unfamiliar with the subject can be misled at times. Just to select a few examples, we are told that the World's climate has for most of the time been very much colder than at present (page 10), ignoring the long spans of the geological past when it has actually been much warmer, with no polar ice; that the strandflat was "eroded by the sea" (page 19); and that a mechanism of great importance to the movement of the Antarctic ice-sheet is basal sliding (page 47), giving the unfortunate impression that it is peculiar to the Antarctic. The caption to a photo of northern Skye (page 32) describes it as "glacial terrain" but the main processes actually depicted are connected with mass movement; sheet-jointing in Yosemite (page 61) is attributed to temperature variations (no mention of pressure release); and the caption to a photo of Bodmin tors (page 60) gives the impression that frost was the major formative process. In all such statements there may well be a grain of truth, but brevity and sometimes an unfortunate choice of words can easily convey quite the wrong idea. The opening page (page 7) is distinctly journalistic ("We are all basically afraid of extreme cold and darkness"); and the inhabitants of the Alps or Scandinavia must be amused to read that "Something akin to panic is induced... every time there is a heavy snowfall".

There are seven chapters: the ice planet; ice environments; glaciers; frozen ground; ice afloat; plants, animals and ice; and Man in the World of ice. Some important subjects are given litte mention: avalanches are dismissed in about 70 words; the section on plants is comparatively thin; and in the chapter on Man, there is virtually no mention of the economic importance and utilisation of the permafrost areas of Siberia, Alaska and Arctic Canada. But the overall impression of the book is undoubtedly attractive and it should find a ready market on the bookstalls.

C. Embleton

C. Embleton is Reader in Geography at King's College, University of London, UK.

Immediacy and surprise

ASTRONOMERS are extremely fortunate members of the scientific community because they have an efficient public relations network. It may be an unwitting PR network — astronomers don't pay for it anyway — but the media do seem to be on their side. Two things are greatly in the subject's favour. First is the immediacy. The results and images from a spaceprobe passing Jupiter, for example, are transmitted and processed with great speed. The time lag between observation and announcement is short. Second is the element of surprise. Time and again the astronomers find things they did not expect. Jupiter and its satellites again furnish two examples. It would have been a brave astronomer who firmly predicted the existence of active volcanoes on Io or a ring around the planet. Pioneer found both. New things seem to crop up wherever the astronomer looks and nothing seemingly interests the media more than novelty coupled with those looks of amazement on the faces of scientists when confronted with something unexpected. Two consequences result: the number of people interested in the subject continues to increase, and astronomy books seem to date quickly, providing ample room and justification for new works and editions.

This year, as in previous years, I am confronted with a large pile of new books and I am again trying to answer the question "Which book would you, young astronomer, old astronomer, amateur or professional, like to find in your stocking on Christmas morning?" The choice is enormous and the answer is far from easy. One which I am sure will go down very well is *The Guinness Book of Astronomy Facts and Feats* (Guinness Superlatives: Enfield, UK; £6.95), compiled by Patrick Moore. It is the quiz fanatics' dream, a fund of answers to questions you probably would not have asked yourself in the first place. Every dip I made into the book produced something of interest and humour. Who would have thought that Le Monnier observed Uranus eight times in four weeks and failed to identify it as a planet, or that one of his observations was later found scrawled on a paper bag which had once contained hair perfume; that the longest living sunspot group lasted for 200 days; that Halley's comet was excommunicated in 1456; that the smallest known galaxy is only 1,000 light years across; that a piece of the Barwell meteorite was found nestling in a vase of artificial flowers on the windowsill of a house in the village? The book is full of them; you can imagine the advertisement, "astound your friends", "impress your colleagues" — but it's all good fun and excellent value. The facts and feats are listed in sections, a random few being Sun, Moon, Jupiter, double stars and galaxies, so they are easily accessible. Eighty-seven pages are taken up by a star catalogue which struck me as being somewhat out of place. The star maps in this catalogue were too small, had no right ascension or declination grid and the bright stars in each constellation were joined in a most unusual, idiosyncratic fashion. And I am sure that 10^{-8} cm as the definition of an Angström unit is easier to comprehend than "one hundred millionth part of a centimetre." Anyway, these are all minor quibbles. I know few astronomers who would not be delighted to receive a copy.

The same can be said of the next book, *Space Art* compiled and written by Ron Miller (Starlog Magazine, O'Quinn Studios: New York; paperback $7.95, slipcase delux $12). We are treated to a multitude of colour plates of astronomical and space science subjects realised by a host of artists. The book continually underlines the usefulness of space art. These paintings synthesise scientific knowledge and data into a visual and concrete form. Flesh is put on to the bones of numbers, equations and theoretical predicitions. Whenever a new phenomenon or discovery comes to light it is the space artist who asks the question, "What would it actually look like to the human eye if you could stand there and see it?". Ron Miller traces the evolution of this art-form from its infancy in 1865, when *From the Earth to the Moon* and *A Trip Around the Moon* by Jules Verne, contained illustrations created by the artist painting for the first time strictly according to scientific fact, through to the present day, where we benefit greatly from such organisations as the NASA Fine Arts Programme. NASA decided that, despite filmed documentation of all their projects, art would give their work a special emotional impact and significance. Miller goes as far as to propose that it was the space art in the popular illustrated magazines and books of the early 1950s that helped rally the taxpayers behind the space programme. Well of course, this is debatable, but the worth of the present book is beyond dispute. It is excellent value for money, a continual feast for the eye and the imagination and an ideal gift.

Let us now turn to two books for the observer. The Mittons, Jacqueline and Simon, have produced a *Star Atlas*

(Jonathan Cape: London; Crown: New York; £1.10). This is a very handy, reasonably priced, 32-page, large-format paperback, half of which is devoted to a description of such topics as mapping the skies, the constellations, star names, magnitudes and the way the atlas is to be used; the remainder contains the maps, 2 for the north and south celestial poles, declinations from 90° to 60°, and 12 for the equatorial region of the celestial sphere, each of these being 5 hr across, allowing some overlap. My first response to this book was to compare it with *Norton's Star Atlas* (Gall and Inglis: Edinburgh; £4.50). Norton's book goes down to magnitude 6.35 and contains slightly more stars than the Mittons'. Norton represents his stars by filled black dots, scaled in half-magnitude steps. The Mittons represent stars by spidery, computer-drawn asterisks, the star magnitudes being indicated to within 0.1 mag by the size of the printed star image (you need a good engraved scale and a magnifying glass to make use of this).

There is considerably more text in Norton than in Mitton, although people who can get most from the atlas do not really need the text. There is a more comprehensive list of doubles, variables, clusters and nebulae in Norton. I prefer Norton's dots to the Mittons' asterisks, although I prefer the Mittons' price to Norton's. However, if I was buying an amateur star atlas I would still save up for Norton.

The second book for the amateur observer is *The Messier Album* by J.H. Mallas and E.Kreimer (Sky Publishing Corporation: Cambridge, Massachusetts; Cambridge University Press: Cambridge; $9.50; £6.95) and I recommend this most heartily. Owen Gingerich provides an historical introduction to Messier and the catalogue is reproduced in facsimile, but the real kernel of the book is the descriptions, drawings and photographs of each object. We are not confronted here with 100-inch Schmidt photographs but with the realistic capabilities of amateur astronomers. Mallas has a 4-inch refractor and he draws and describes exactly what can be seen of each Messier object using this instrument. The photographs were obtained by Kreimer using a 12.5-inch *f*/7 reflector, with the guiding head, low-temperature, plate camera at the newtonian focus. About eight pictures could be obtained during a 4-hour observing session. The book ends with a series of colour photographs and again the technique used to obtain each of these is given in detail. Everyone with a telescope should have this book.

The remainder of my Christmas books have a bias either towards the fundamentals of astronomy or towards space science. *Basic Astronomy* by Patrick Moore (Ian Henry: Hornchurch, UK; £3.95) is a modest, small-format second edition of the 1969 original. The production quality reminds me of the books published around the time of the second World War, most of the photographic reproductions being worse than one would see in the average newspaper. The figures suffer from *déja vu*, all seemingly having been plucked from some ancient tome. The text is vintage Patrick Moore and I like it. You cannot help being infected by his enthusiasm. He writes about what he knows; you could drive a cart and horses through the omissions. At the same extremely elimentary level is *Discovering Astronomy* by Jacqueline and Simon Mitton, Institute of Astronomy, University of Cambridge (Longman: Harlow, UK; Prentice-Hall: Englewood Cliffs, New Jersey; £4.75) . I quote the address of the authors in full because this is given in large letters on the cover. We are also told on the cover that "For the inquiring young person there is no first-step introduction to the 'new' astronomy written with the authority commanded by authors at Cambridge Univeristy's Institute of Astronomy." Why should we care where the authors come from as long as they have written a good book? I am sure that an author could write a 'first step' into astronomy without going anywhere near a university, never mind Cambridge. Inside we find a superbly illustrated 90-page introduction to astronomy, ideal for the infant and junior school room. Adults wishing to take more than one step into astronomy should start elsewhere. However, I would not specifically recommend *Foundations of Astronomy: From Big Bang to Black Holes* (David and Charles: Newton Abbot, UK; £5.95) by Richard Knox. It is billed as a new and radically different introduction to astronomy for the lay or student reader. I found it to be neither new nor radical but simply a reasonably competent,

Zoogeography and Diversity in Plankton

Edited by S. van der Spoel and A. C. Pierrot-Bults

The proper management of fisheries and man's other oceanic activities depends on a detailed knowledge of marine primary and secondary producers. Whilst primary producers have been well covered in the literature, the secondary producers have been, until now, comparatively neglected. Drs. van der Spoel and Pierrot-Bults have set out to redress the balance by drawing together leading workers from seven countries to write this book on zooplankton.

Throughout, the authors make use of the most recent data and take account of the newer theories and methods that are emerging. Together, they have produced a comprehensive account of plankton zoogeography throughout the world that will serve as an authoritative reference for students and research workers in marine biology.

methodical plod through the usual topics.

As time is short and the number of simple astronomy books enormous, it is important that the new reader, young or old, does not waste time or become discouraged by making the wrong choice for his introductory text. The Americans come to our rescue here. I have previously praised *University Astronomy* (Saunders) by J.M. Pasachoff and M.L. Kutner, and *New Horizons in Astronomy* (Freeman) by J.C. Brandt and S.P. Maran, and I have no hesitation in adding the works of William J. Kaufmann III to this short list. He has produced a trilogy of books for the general reader. I have before me *Planets and Moons* and *Stars and Nebulae* (Freeman: San Francisco and London; hardback £8 and £8.20, paperback £3.95 and £4.10). The line drawings are superb, clear, uncluttered, eminently understandable and a perfect example to every writer of how it should be done. The illustrations are beautifully reproduced and relevant to the text. Not for Kaufmann the collecting together of any handful of NASA prints just to add spice. The text hammers home the important points, the new ideas, the problems and the next steps. It is unfair to single out one topic from the rest but I will. Kaufmann's exposition of the birth, life and death of stars is masterly. This is how introductory books should be written. There is no need to plod through mediocrity when the best is so easily available.

Saturn and Beyond (Lothrop, Lee and Shepard; New York; $7.95) by Isaac Asimov, is a rather pedantic stroll through the features of Saturn, Uranus, Neptune and Pluto. We are told that this is Dr Asimov's 199th book. I got the impression that Dr Asimov has slightly run out of steam on this one. Why are rings common? How many theories of ring origin are there? Why do these planets have similar spin periods? Why haven't we detected planets beyond Pluto? Why were Neptune and Pluto so difficult to discover? Why are the spin axes at different inclinations, and why are the interior structures of these planets dissimilar? We learn too little about these problems in this book; we are treated to too many tables, too little explanation, too few illustrations. Even the US Naval Observatory's photograph of Pluto and Charon, arguably one of the most exciting outer planetary photographs of the decade, is missing. Never mind, Kaufmann's book has it.

The Astronomy Data Book by J. Hedley Robinson and James Muirden (David and Charles: Newton Abbot, UK; £6.95) is a revised but little improved version of the 1972 original. I must not be too harsh with this book because it contains many useful tables listing astronomical objects and their characteristics. It is also aimed much more towards the amateur astronomer than C.W. Allen's classic *Astrophysical Quantities* (Athlone Press: University of London). However, I cannot help but feel that it could be made much better. The Glossary is very poor, and throughout the book the definitions need tightening up, with more quantitative assertions as opposed to qualitative ones. The few figures the book contains leave much to be desired and many more figures are needed. The knots in which the authors tie themselves as they try to describe the Moon's orbit, collars on Venus, zodiacal light and sidereal time, to mention but a few, have to be read to be believed. The new index is a great help.

Finally, let us have a look at four space books. Closest to us in a physical sense is A.T. Lawton's *A Window in the Sky* (David and Charles: Newton Abbot, UK; £6.50). Lawton lifts the astronomical observer through the Earth's atmosphere and has written a most readable account of the achievements, possibilities and problems of observing from satellites. He discusses the astronomical objects that benefit most from this type of observation and the instrumentation required. The main emphasis is on the non-visual parts of the electromagnetic radiation spectrum, but even so I was rather surprised about the omission of a chapter on the Space Telescope.

Passage to Space: The Shuttle Transportation System (William Morrow; New York: $6.95) by Charles Coombs, and *The Space Shuttle: Its Story and How to Make a Flying Paper Model* (Lothrop, Lee and Shepard; New York; $6.50) by Frank Ross Jr, are both short, profusely illustrated, simple accounts of the USA's next step in space exploration and are both aimed at the younger reader. There is very little to choose between these books; they are both excellent introductions to the subject. However, if I must choose, I would buy Frank Ross's (incidentally, the model flies beautifully).

We end this review with a flight of fantasy. *The Handbook for Space Pioneers* (Westbridge Books/David and Charles: Newton Abbot, UK; Grosset and Dunlap: New York; £5.95) by L. Stephen Wolfe and Roy L. Wysack, discusses the activities of a hypothetical organisation known as GAIL, the Galactic Association of Intelligent Life. Starships have roamed the neighbouring regions of our Galaxy searching for habitable planets. The book introduces pioneers who fancy leaving Earth to the physical characteristics and state of development of eight new worlds and it also provides a brief review of the starships that will be used to transport these emigrating Earth citizens. This book should appeal to all space flight enthusiasts and science fiction fans. The fun the authors had in producing it sparkles from every page.

Carcinogenesis

Aims and scope

Carcinogenesis has been designed as a multi-disciplinary journal bringing together all the varied aspects of research which would ultimately lead to the prevention of cancer in man. The journal will publish full papers and short communications which warrant prompt publication in the areas of carcinogenesis, mutagenesis; factors modifying these processes such as DNA repair, genetics and nutrition; metabolism of carcinogens; the mechanism of action of carcinogens and promoting agents; epidemiological studies; and the formation, detection, identification, and quantification of environmental carcinogens. Accepted manuscripts will be typeset, with high quality reproduction of photographs and illustrations, and the time from acceptance to publication will be no longer than 4 months and often less.

Leisure Reading from
The Institute of Physics

Science in Action
John Lenihan
Illustrated by John B. Flemming

A collection of entertaining and informative essays exploring the world of science and how it affects our daily lives.
Illustrated with nearly 100 cartoons.
. . . Witty, penetrating and often uncomfortably wise; a brilliant little book with knowledge made as palatable as after-dinner conversation. Glasgow Herald.

. . . It will appeal to professional scientists because, although non-technical, it raises some challenging and fascinating trains of thought; it would provide superb background reading for fifth and sixth formers; and it gets special marks from me for debunking a number of widely-held myths in a firm but kindly way that is not the least bit pompous or condescending. Professor C. A. Taylor in Physics Bulletin.

1979 x + 223 pp. 94 line illus.
0-85498-035-0 £7.50

A Random Walk In Science
Compiled by **R. L. Weber**
Edited by **E. Mendoza**

This book is a delicious conception of aphorism and anecdote, verse and memorabilia, a selection of the writings and remarks of scientists . . . often light-hearted in style but rarely less than perceptive and often remarkably illustrating. British Book News.

1973 xviii + 206 pp + 12 pl. 30 B&W, 32 line illus.
0-85498-027-X £6.95

The Harvest Of A Quiet Eye
A selection of scientific quotations
Collected by **A. L. Mackay**
Edited by **M. Ebison**

Not just scientists but artists, poets, philosophers, theologians, politicians and other miscellaneous mortals are quoted . . . The book can be useful in many ways to many people, but supremely it is for browsing and relishing. The Wall Street Journal.

1977 xii + 192 pp. 24 line illus.

newly on the market

Pipette tip. Variable Volumetrics now introduce a new yellow pipette tip to cover the range 5–250 μl. The tip is called the Video Bonus Tip and features a very small hole. This helps to expel the last drop and thus to ensure accuracy.
Circle No. 124 on Reader Enquiry Card.

A range of the Variable Volumetrics pipette tips

Inhalation chamber. Wahmann. A proven and tested 200-l inhalation chamber custom engineered for research and toxicity testing of a large variety of substances is now available from Wahmann manufacturing. The chamber, of stainless steel construction, can accommodate removable animal caging and racking for a variety of animal species and is thoroughly factory tested to maintain a negative pressure for a specified period. The chamber features sampling ports and particulate measuring instrumentation to meet any specific requirements. In addition, blowers, filters, illumination and viewing ports as desired are readily available. A free brochure with further information is now available.
Circle No. 125 on Reader Enquiry Card.

Microwave oven system. Photovolt Corporation introduces a new microwave oven system for fast and accurate moisture measurements of food, dairy and pharmaceutical products. Called the Apollo Mark XII, the system gives results in 3 min. An LED readout displays either per cent moisture or per cent solids. To operate the Apollo, samples are placed directly in the oven and the built-in electronic balance automatically tares, weighs and sets itself to 100%. When the sample is dry the oven automatically turns off. Operational instructions are shown on the LED display. Microprocessor control makes the whole sequence automatic.
Circle No. 126 on Reader Enquiry Card.

Balances with an automatic weighing feature. Arbor. A new series of balances from Arbor Laboratories, using advanced microprocessor technology features the new Auto Weight/Auto Tare. This provides immediate weighing results without the 'flutter' associated with conventional weighing systems. There is also a new auto precision feature, with which the user can simply dial in the desired level of precision required.
Circle No. 127 on Reader Enquiry Card.

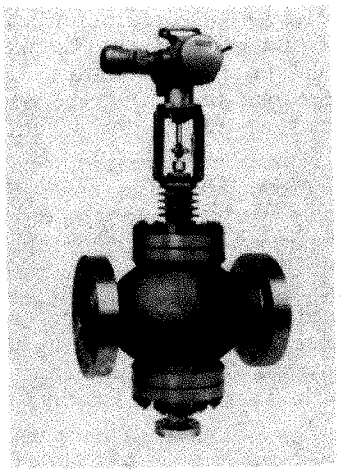
Sealing film. Sealonfilm is now available from Alpha Laboratories. This is a tough sealing plastic film which will adhere to pottery, glass or metal and give an airtight, leakproof seal which can be used in the temperatue range -70 to 55 °C. It has high resistance to ethanol, methanol, concentrated acids and alkalis and is also resistant to organic solvents.
Circle No. 128 on Reader Enquiry Card.

Twin strainers. Royles. A new brochure describes the Royles Type 'G' twin strainer detailing materials of construction, component identification chart, weights, dimensions and a flow rate/pressure drop chart as an indication to size and capacity. Based on the provision of two strainer cages in a single body combined with suitable valve gear mechanism, a twin strainer allows one cage to be removed and cleaned while the other remains in operation. The standard sizes are from 3″ to 18″ (larger sizes also available as specials) and are capable of handling from 110 to 3,800 gallons per min given a 2 p.s.i. pressure drop through the unit.
Circle No. 129 on Reader Enquiry Card.

Light scattering photometer. Chromatix. A new Application Note describing the use of the KMX-6 low angle laser light scattering photometer to determine molecular weights and molecular weight distributions of low molecular weight polystyrenes is now available from Chromatix.
Circle No. 130 on Reader Enquiry Card.

Electronic top-loading balances. Brinkmann Instruments announce the introduction of two new electronic top-loading balances offering much greater capacities at accuracies of 400 g to 0.001 g or 3,000 g to 0.01 g. These new balances are microprocessor equipped and are available with optional BCD-output for connection to printers, calculators, and other data handling equipment.
Circle No. 131 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.



Heated gas cell. Specac. Gas cell 5700 from Specac has been designed so that spectroscopic studies can be made of gases and vapour at temperatures above ambient up to 250°C. This enables vapour and gas spectra to be obtained of substances that are in either the solid or liquid phase at room temperature. This cell has a 120-W heater around the body which enables the temperature of the sample to be raised to 250°C. A vacuum stop cock is fitted which is made of stainless steel and operates over the whole working temperature range of the cell. An injection septum is fitted for the introduction of gas or liquid sample. The seals in the cell are made either from silicone rubber or PTFE. A copper-constantan thermocouple is supplied with the cell and passes through a vacuum tight seal into the gas cavity so that the temperature of the gas sample can be monitored.
Circle No. 132 on Reader Enquiry Card.

The Specac gas cell 5700

Mechanical booster pump. Edwards. The EH4200 booster vacuum pump is now available from Edwards. Suitably backed, it has a pumping speed of 3,400 $m^3 h^{-1}$ and ultimate pressure of 1.3×10^{-5} mbar. Pumps in the Edwards EH range, which now cover capacities from that of the EH4200 down to 400 $m^3 h^{-1}$, have higher speeds and compression ratios than other pumps of similar dimensions. Hydrokinetic drive allows them to work at optimum speed and with minimum power demand throughout the entire pressure range, and whatever the gas load.
Circle No. 133 on Reader Enquiry Card.

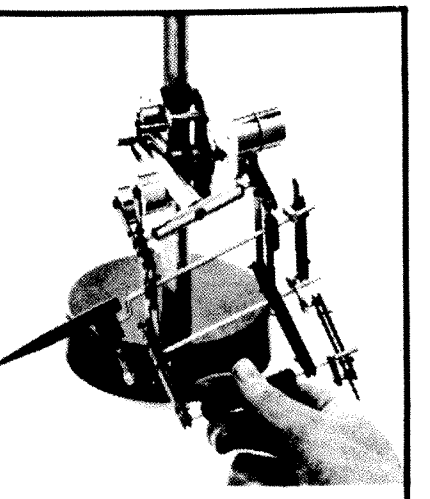
Steam-transforming valve. Arca-Regler. The steam-transforming valves from Arca-Regler have the capacity to reduce and at the same time desuperheat. The design includes a pressure-balanced plug, which is also the explanation for the relatively small actuator. The four-flange body, taken from a standard valve programme, has at the bottom flange a connection facility for the cooling water line. The mixing of the reduced steam with the cooling water takes place in an area of heavy turbulences directly behind the seat of the reducing plug. The valve shown in the figure has been constructed for a conventional power station, where superheated steam of 106 bar and 535°C (±10°C) is reduced and mixed with feed water of 130°C.
Circle No. 134 on Reader Enquiry Card.

The Arca-Regler steam-transforming valve

Dual piston pump for HPLC. Schoeffel. A dual piston, constant volume pump for HPLC has been introduced by the Schoeffel Instrument Division of Kratos. The pump includes a full complement of the necessary valving and flow controls for immediate use with any LC detector and injection valve. It provides precise control of flow rate from 0.1 to 9.9 ml min^{-1} with an accuracy of better than 1% (using methanol or water at 2 ml min^{-1}). Operating pressure of the pump may be as high as 6,000 p.s.i. A detailed description of the HPLC pump and its corresponding accessories and system components is available from the company.
Circle No. 135 on Reader Enquiry Card.

Convection ovens. Boekel. Double wall electric gravity convection ovens are now available from Boekel. These ovens are used for sterilising, drying, conditioning, pre-heating, baking, evaporating, annealing, dehydrating, and curing in any laboratory. The double wall construction includes an all-metal chamber and an outside sheathing of Marinite XL. All walls and doors are insulated with 3 inches of rock wool. Approximately 80% of radiant heat up to 460°C is reflected; destructive heat scaling up to 660°C is resisted.
Circle No. 136 on Reader Enquiry Card.

Block digestion systems catalogue. Techne announces the publication of a new 4-page catalogue describing all component and accessories of its new block digestion systems. These units are designed for sample preparation before analysis of grain, food products, soil, water pollutants and chemicals.
Circle No. 137 on Reader Enquiry Card.



1979-80 Biochemicals catalogue. Miles. The 1979-80 edition of the Miles Biochemicals Catalog is now available, free of charge, from Miles Research Products. The catalogue's 150 pages include listings of over 2,000 product sizes and types in 10 different product groups. There are detailed descriptions of 980 products under the headings of immunochemicals, lectins, blood proteins, electrophoresis apparatus and reagents, polypeptides, nucleic acids, recombinant reagents, enzymes and companion reagents. To help locate specific products, listings are cross-indexed under major subject and individual product headings. Suggested applications, with relevant cross references, are also provided for most products.
Circle No. 138 on Reader Enquiry Card.

Light sources. The Oriel Scientific range of light sources vary from simple tungsten halogen types for general illumination to ultra-high power arc lamp systems with a comprehensive range of associated accessories. Arc systems use xenon, mercury and mercury-xenon lamps covering the range 75 — 2,500 W. Specific sources yielding high ultra-violet and infrared outputs are available, together with spectral calibration lamps and hollow cathode lamps. The range is completed with pulsed sources covering the microsecond and nanosecond regions.

Cine equipment for Zeiss Axiomat. Zeiss. A 4-page illustrated fact sheet from Zeiss describes the latest possibilities for cinematography, time lapse, and TV-microscopy now available for the ultra-stable Axiomat System. The high resolution and image contrast produced by the Axiomat are relayed to the film via a 1:4 zoom system to capture every minute specimen detail and to allow for any special effects.

Universal animal isolator. Vickers Medical has now developed a universal animal isolator, which provides maximum security, a controlled environment and is easier to handle. The isolator comprises a large sealed and transparent PVC envelope, supported by a light metal frame, with its own filtered and pressurised air supply. Completely self-contained, the equipment is mounted on a mobile stand and requires no structural change in a laboratory.

SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.
A varied range available. All simple to operate.

Constant rate injector accessory. Dohrmann. A new sample introduction system is now available that enables users of Dohrmann chemiluminescence nitrogen systems to obtain low level nitrogen analyses in light hydrocarbons with 20 parts per billion (p.p.b.) repeatability. The constant rate injector (CRI) accessory is also intended to complement existing Dohrmann DN-10 or DN-100 systems. Sample injection is virtually operator independent. Effective range of the system is 0 p.p.b. to 200 p.p.m. Sample requirement is 250 μl minimum. A 5-digit data display and provision for recorder are included.

Balances and scales catalogue. Brinkmann announce the availability of the new Sartorius Balances and Scales '80 Catalog, BR 377B. This catalogue is the most comprehensive and descriptive piece of Sartorius literature to date including all the latest innovations in weighing: new analytical top-loaders offering accuracy to 0.1 mg and fully automatic electronic weighing; new dual-range top-loaders; new exclusive super-range top-loaders which extend the readability of the more accurate 'fine' range to the full capacity of the balance. Plus a complete line of every conceivable type of balance or scale for virtually every weighing need. For further information on Sartorius Balances and Scales, please request catalog BR 377B.

High performance filters and purifiers. LabClear has introduced a line of disposable and refillable gas filters, and rechargeable gas purifiers called OxyClear. Both provide high performance filtration and purification, with great reliability. The LabClear filters remove moisture, oil and other foreign matter from inert gases such as hydrogen, helium, nitrogen and argon. The filter contains a molecular sieve, and Drierite desiccant, which changes colour with moisture absorption. The filters are manufactured with clear plastic bodies for easy viewing of the colour indicators. LabClear offers a disposable 200-cm^3 filter for inline service and refillable 200-cm^3 and 400-cm^3 models for either inline or free-standing bench applications. The filters are offered with 1/8″ or 1/4″ fittings. The company also announces handy refill kits of premixed Drierite, sufficient to refill a 400-cm^3 unit.

LabClear filters and purifiers

Automatic oxygen monitor. Neotronics. Automatic oxygen monitoring with Neotronics Otox 90s linked to nitrogen control valves permits operators dispensing radioisotopes to concentrate on the job in hand and not worry about oxygen levels inside the manipulation cabinets they are using. The Otox 90 is designed for both field and fixed installation use and operates either from mains supply or its own integral Ni-Cd battery. A resolution in 0.1 per cent steps over 0–35 per cent oxygen is provided. Audible alarm points may be set either side of a desired level to give immediate warning of excessive deviations.
Circle No. 145 on Reader Enquiry Card.

Spill Control Pillows. Lab Safety Supply. Spill Control Pillows from Lab Safety Supply can be used to absorb spills of hazardous chemicals, biologicals or radioactive materials. Pillows are applied directly to the spill, absorbing most spills within 30 s. No clean-up of neutralisers or absorbents is necessary — the Pillow completely contains the spill-saturated absorbent for safe, convenient and fast disposal.
Circle No. 146 on Reader Enquiry Card.

Balances. Weighdata. Three new models in the Thor range manufactured by Weighdata are now available. The DK4/13 is a dual range model accurate to either 1 g in 12 kg or, using the same balance, 0.1 g in 4 kg. The M4000 is a single balance in a new compact casing accurate to 0.1 g in 4 kg. Both models are designed for laboratories and small chemical process plants for both weighing and component counting. The third new design is the DT2500, a single balance accurate to 0.01 g in 2,500 g for general laboratory use.

Electromechanical and electronic components catalogue. Radiatron Components has introduced a new version of its popular shortform catalogue. As its predecessor, it is intended to provide a brief visual summary of the Company's capability in precision electromechanical and electronic components and systems. Products covered in the 'Shortform' include interconnection devices, instrument cases, boxes and housings, collet fixing knobs, relays, miniature cooling fans, a wide selection of switches, surge arrestors, and a host of panel components. The 'Shortform' can be obtained on request and comes with a special reply-paid card to facilitate further response and consequent assistance.
Circle No. 148 on Reader Enquiry Card.

Multichannel recorders. Gulton. Features of the fixed range and plug-in signal conditioner chart recorders from Gulton include super shock resistance (15 g for 11 ms), dry thermal writing, recording in any orientation, plug-in signal conditioners for measurement versatility, 125 Hz frequency response, slim profile for true portability, rugged steel encased coaxial styli, pushbutton chart speed selection, right hand event marker and remote chart on/off.
Circle No. 149 on Reader Enquiry Card.

Brochure on films. Kodak. A new brochure entitled "KODAK Films for Fluorography and Spot Film Radiography" (M3-149) is now available from Eastman Kodak Company. The brochure offers complete product descriptions of Kodak PF film, a medium-contrast, high-speed orthochromatic film, and Kodak PFC and Kodak X-Omat GR films, high-contrast, medium-speed orthochromatic films. The latter film is available to meet the needs of spot-filming cameras that require 10 cm × 10 cm square-format films. Charts, sensitometric comparisons, and processing recommendations are included to assist diagnosticians in film selection and quality control procedures. Also listed are film features, codes and catalogue numbers and film sizes.

APPOINTMENTS VACANT

UNIVERSITY OF EDINBURGH
CENTRE FOR REPRODUCTIVE BIOLOGY
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY
LECTURER (NON-CLINICAL)

Applications are invited for the above post in the Department of Obstetrics and Gynaecology. Preference will be given to those who have experience in the biochemistry of reproduction. The successful candidate will be expected to conduct research in reproductive endocrinology and to participate in the teaching of undergraduate and supervision of postgraduate students. There are excellent facilities for collaborative work with clinicians in the Royal Infirmary and scientists in the MRC Unit of Reproductive Biology.

Salary on the scale £4,333 to £8,992 per annum. USS Superannuation.

Enquiries may be addressed to Professor D T Baird, Department of Obstetrics and Gynaecology, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh, (031 229 2575)

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (8 copies) including curriculum vitae and the names and addresses of three referees should be lodged not later than 21st December 1979. Please quote Reference 1085. 3846(A)

ST BARTHOLOMEW'S HOSPITAL
West Smithfield,
London EC1A 7BE

RESEARCH ASSISTANT/ TECHNICIAN
DEPARTMENT OF MEDICAL MICROBIOLOGY

Applications are invited from Technicians and Graduates (MSc/PhD) for a position available for one year in the first instance, to work on a research project investigating the serology of anaerobic bacteria and its relationship to pathogenicity in diagnostic medical microbiology.

Applicants with training and/or experience in serological techniques, microbiology and immunology will be considered. The work will involve animal studies, the preparation and purification of microbial antigens, preparation and purification of antisera and immunofluorescent techniques.

Salary according to experience and the Whitley Council Scale £6,228 to £7,803 plus London Weighting.

Applications stating age, qualifications, present post, past experience and the names of two referees, should be sent to the Personnel Department, within three weeks of the date of publication, quoting Reference RP 90/77. 3883(A)

ATTACHE DE RECHERCHE EN ECOLOGIE VEGETALE

Le Centre de recherches écologiques de Montréal (CREM), un organisme de recherche de l'Université de Montréal, dispose d'un poste d'attaché de recherche en écologie végétale, avec rang d'adjoint, d'agrégé ou de titulaire selon expérience. Le candidat doit posséder un PhD ou un DSc, avoir une bonne connaissance des différents types de végétation de l'est de l'Amérique du Nord, des méthodes d'échantillonnage et d'analyse de la végétation, puis avoir une expérience en photo-interprétation avec une ouverture en pédologie. Ce chercheur, le plus souvent au sein d'équipes pluridisciplinaires, sera responsable de la coordination des recherches et des études en écologie végétale dans le cadre d'inventaires axés sur la caractérisation d'écosystèmes, d'études d'impacts, de projets d'aménagement et de zonage écologiques, etc. La langue de travail sera le français. Salaire selon la convention collective des professeurs. Le curriculum vitae et deux lettres de recommandation doivent être adressés le plus tôt possible par courrier recommandé au Dr Raymond McNeil, CREM, Université de Montréal, CP 6128, Succ. "A", Montréal, Québec H3C 3J7, Canada. Le poste doit être comblé le plus tôt possible à partir du 1er Janvier 1980. W585(A)

POPULATION/ QUANTITATIVE GENETICIST
THE DEPARTMENT OF MEDICAL GENETICS
THE UNIVERSITY OF BRITISH COLUMBIA
Canada

Invites applications for a faculty appointment from individuals with demonstrated excellence in research in the field of population or quantitative genetics. Candidates should be capable of developing and teaching courses in population genetics.

The position is available July 1st, 1980. Members of this department act as consultants to the Health Surveillance Registry of British Columbia and, with the division of vital statistics of the province, have a record linkage project which together provide a unique data base for research.

Applicants should send an up-to-date curriculum vitae and names of three references, by January 1st, 1980, to Dr P A Baird, Dept of Medical Genetics Faculty of Medicine, University of British Columbia, Vancouver, BC, V6T 1W5 Canada. The University of British Columbia offers equal opportunity for employment to qualified male and female candidates. W582(A)

Pharmacologist

Biosciences Research Centre, Epsom

A Pharmacologist is required to investigate novel animal systems that are designed to detect compounds that might be useful for the treatment of allergies. Applicants should have a good first degree and, preferably, relevant experience to PhD level, since they would be expected to contribute ideas and techniques to the work.

The Company offers a competitive salary, a non-contributory pension scheme and free life assurance. Flexible hours are worked on this Site.

For an application form please write to or telephone the **Site Personnel Manager, Beecham Pharmaceuticals Research Division, Biosciences Research Centre, Great Burgh, Yew Tree Bottom Road, Epsom, Surrey KT18 5XQ. Telephone: Burgh Heath 53344 (ext 2207). Closing date: December 21, 1979.** 3874(A)

Beecham Pharmaceuticals

THE UNIVERSITY OF TEXAS AT AUSTIN
ASTRONOMY DEPARTMENT
invites applications for
TWO ASSISTANT PROFESSOR POSITIONS

These positions are regular, tenure-track assistant professorships with duties that include both teaching and research. Available research facilities include: the optical telescopes (2.7, 2.1, 0.9, and 0.8 m) of McDonald Observatory, the 2 mile 82 cm interferometer of the University of Texas Radio Astronomy Observatory, the 4.9-m antenna of the Millimeter Wave Observatory, as well as the CDC Cyber 170/750 campus computers.

Applications should include: a description of educational background, teaching, and research experience; a list of all publications; preprints of papers submitted but not yet published; and a statement of current research interests and future plans. Applicants should request at least three scientists who know the applicant personally to send letters of recommendation directly to: P. Vanden Bout, Chairman, Astronomy Department, RLM 15.220, University of Texas at Austin, Austin, TX 78712. Applications and letters of recommendation should be received by 1980 January 15.

The University of Texas at Austin is an Equal Opportunity Employer with an Affirmative Action Program. We encourage and welcome applications from all qualified persons regardless of sex, race, creed, national origin, or non-disqualifying handicap. W583(A)

QUEEN MARY COLLEGE
(University of London)
QMC INDUSTRIAL RESEARCH LTD
MICROBIAL ENHANCEMENT OF OIL RECOVERY
THREE RESEARCH ASSISTANTS

A programme of research is being instituted in collaboration with the Department of Plant Biology on Microbiology to develop *in situ* bacterial methods for the enhancement of crude oil recovery, with particular reference to problems of North Sea reservoirs. In the first phase, sponsored by the Department of Energy, three research assistants are being sought for a three-year period, one at postgraduate and two at post-doctoral levels. It is intended to start the programme as soon as staff can be recruited.

Applicants should have a sound background in microbiology with a knowledge of and an interest in biochemistry and genetics. Experience of working with anaerobic bacteria is desirable but not essential.

The initial salaries (under review) are in the ranges £4,333 to £5,488 plus £740 London Allowance, at postdoctoral level and £3,775 to £4,333 plus £740 London Allowance at postgraduate level.

Applications and requests for further details should be sent to Dr J Hume, QMC Industrial Research Ltd, 229 Mile End Road, London E1 4AA. 3897(A)

THE UNIVERSITY OF TEXAS
HEALTH SCIENCE CENTER AT DALLAS
ANATOMIST

The Anatomy Program in the Department of Cell Biology invites applications for a tenure-track position at the Assistant Professor level. PhD, MD or equivalent, postdoctoral training, and experience teaching human gross anatomy are required.

Responsibilities include teaching in the Human Gross Anatomy Course for first-year medical students and participation in the Department's Graduate Program. Candidates will be expected to conduct independent research in some aspect of biological structure, functional/evolutionary morphology, developmental biology or reproductive biology.

Curriculum vitae, brief description of research program, and names of three referees should be sent to: Dr A P Santa Luca, Faculty Search Committee, Department of Cell Biology, The University of Texas Health Science Center at Dallas, 0.S.C. Texas 75235. The University of Texas Health Science Center at Dallas is an Equal Opportunity/Affirmative Action Employer. M/F/H. W598(A)

UNIVERSITY OF LONDON
INSTITUTE OF NEUROLOGY
POST-DOCTORAL ASSOCIATE

Applications are invited for a position in a research group supported by a 5-year MRC programme grant studying the role of 5-hydroxytryptamine in the brain. The post is suitable for a post-doctoral worker from the neurochemical/pharmacological area. Behavioural or neutritional interests would be an advantage. Salary probably between £5,073 to £6,517 (inc. London weighting). A higher salary may be possible for a particularly well-qualified candidate.

Curriculum vitae with names of 2 referees by 7 January 1980 to Prof G Curzon, Institute of Neurology, 33 John's Mews, London WC1. 3886(A)

UNIVERSITY OF SASKATCHEWAN
DEPARTMENT OF BIOLOGY
POSTDOCTORAL POSITION

Available to investigate the use of liposomes for the uptake of macromolecules and organelles into plant protoplasts. Candidate should have strong background in biochemistry and some knowledge of electron microscopy.

The position is available immediately for two year term (possibly renewable for a third year) at a salary of $C 12,500.00 to $C 13,500.00.

Interested candidates should send curriculum vitae and 3 letters of recommendation to Dr L C Fowke, Dept. of Biology, University of Saskatchewan, Saskatoon, Sask., Canada S7N 0WO. W595(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
SCHOOL OF PATHOLOGY
POST DOCTORAL RESEARCH ASSISTANT
Research in Chemical Carcinogenesis

Applications are invited for the above post funded by the Cancer Research Campaign for 2 years from 1 January 1980 or as soon as possible thereafter. The work is concerned with various aspects of the malignant transformation of cells by nitrosamides and involves cell culture techniques. A background in Microbiology and Molecular Biology would be advantageous. Starting salary depending on age and experience within the range £4,073 to £6,228 including London allowance.

Applications including a curriculum vitae and the names and addresses of two referees should be sent to Dr J P Roscoe, School of Pathology, The Middlesex Hospital Medical School, Riding House Street, London W1P 7LD. 3879(A)

UNIVERSITY OF REGENSBURG
Germany, Bavaria
POSTDOCTORAL FELLOWSHIP
In Biochemistry

Candidates (PhD in chemistry or biochemistry) should be interested in work on the biosynthesis, structure and function of membrane glycoproteins of halobacteria and eucaryotic microorganisms.

Experience in biochemical methods is essential. Salary will be about DM40,000 p.a. A curriculum vitae, copies of former work and the names of referees should be sent to: Institut für Biochemie, Genetik und Mikrobiologie, Lehrstuhl Biochemie I, Universität Regensburg, Universitätsstraße 31, 8400 Regensburg FRG, Prof. Dr M Sumper. W584(E)

UNIVERSITY OF ABERDEEN
PHYSICIST
(Lecturer)

in Department of Bio-Medical Physics and Bio-Engineering to join radio-nuclide clinical service team and contribute to internationally known programme in radio-nuclide emission tomography. Ability to provide support also for EMI brain and body scanners an advantage. Some teaching duties to MSc (Medical Physics).

Salary on Lecturer Scale £4,333 to £8,992 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 4 January 1980. 3866(A)

THE UNIVERSITY OF NEW SOUTH WALES
Sydney, Australia
SCHOOL OF APPLIED GEOLOGY
LECTURER (GEOSTATISTICIAN)

Duties include the instruction of 3rd and 4th year undergraduates and postgraduate students in the applications of statistics and computers to geology. The successful applicant will be expected to assist in the development of major research programmes in Mineral and Energy Resources (especially in interpretation of exploration data), and in Hydrogeology and Engineering Geology.

Applicants should have a higher degree in a relevant geoscience subject. Teaching experience is an advantage but is not essential; industrial experience is desirable. This position is available on a fixed term contract for three years.

Salary per annum: $A16,291 range $A21,401.

Commencing salary according to qualifications and experience.

Applications close 31 December, 1979.

Full information about conditions of employment and method of application can be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 3865(A)

CSIRO AUSTRALIA
Research Scientist
Division of Horticultural Research Adelaide

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

GENERAL: The Division, which has laboratories at Adelaide, SA and Merbein, Victoria, conducts applied research on grapevines and a range of subtropical and tropical fruit crops. This is associated with a basic research program on the physiology of horticultural crops. Current programmes of the Division that are relevant to this position include research on the biogenesis of higher plant chloroplasts, anatomical investigations of plant parasitic nematodes, ultrastructural studies of the pollination process of selected perennial plants, and EDAX studies of the distribution of inorganic elements in the organelles of plant cells. Facilities: The Division has a high resolution electron microscope capable of being used in both the scanning and transmission modes. It is equipped with EDAX facilities. Also available is freeze-etch equipment and a scanning electron microscope.

LOCATION: The appointee will be located at the Adelaide Laboratory.

DUTIES: An experienced cell biologist with specialist skills in light and electron microscopy is sought to work in the broad area of the developmental anatomy of higher plants. The appointee would be expected to bring to the Division expertise in ultrastructural and associated techniques and to develop an independent research programme.

QUALIFICATIONS: A PhD degree or equivalent with experience of light microscopy and of transmission and scanning electron microscopy. Familiarity with EDAX and/or freeze-fracture techniques would be an advantage.

TENURE: Indefinite with superannuation.

SALARY: Senior Research Scientist/Principal Research Scientist: A$20,198 — A$27,212 pa.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 491/058 should reach:-

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 5th January 1980.

Applications in USA and Canada should be sent to:- The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, NW, Washington, DC, 20036, USA 3895(A)

Applications are invited for a position at the EUROPEAN MOLECULAR BIOLOGY LABORATORY in Heidelberg, Federal Republic of Germany, as
Technical Assistant

The successful applicant will work on the isolation and analysis of nucleic acid from bacterial and animal viruses, but some experience of microbiology and/or cell biology will be useful. Familiarity with chromatographic and electrophoretic methods and use of radioactive isotopes is essential.

Applicants should have had appropriate technical training together with experience in the above techniques. Knowledge of English and German is essential.

The salary offered to the successful candidate will be between DM2200 and DM2600 monthly, in addition to which certain allowances are payable, depending on personal circumstances.

Please write briefly for an application form, quoting reference no: 79/22, to:

EMBL, Personnel Section, Postfach 10.2209, D — 6900 Heidelberg, Germany. W589(A)

Opportunities in Metabolic Studies

G.D. Searle is a leading international Pharmaceutical Company with its main U.K. headquarters at High Wycombe in Buckinghamshire. We currently have vacancies for a Mass Spectroscopist and a Biochemist in our Metabolic Studies Department, which is involved in studies of the metabolism and pharmacokinetics of drugs in animals and man.

Mass Spectroscopist

(Ref. MS/R52)

A Mass Spectroscopist is required to supervise the Mass Spectrometry group, which provides g.l.c. and g.c.-m.s. support for metabolism studies and provides a service to synthetic organic chemists for structure elucidation of compounds undergoing research and development. This post would suit a PH.D Chemist with experience in the application of g.c.-m.s. to the analysis of drugs and metabolites in biological fluids.

Biochemist

(Ref. B/R54)

A Biochemist is required to assist in carrying out drug metabolism studies in experimental animals and man. Applicants should have a degree or equivalent qualifications in Biochemistry or Biochemical Pharmacology, and should preferably have some experience of radioisotope and chromatographic techniques. Some experience of animal work would also be of value.

We offer competitive salaries, and our terms of employment include 4 weeks' holiday per year, contributory pension scheme, private health insurance scheme, sports and social club, and subsidised cafeteria.

Please apply, quoting the appropriate reference, to Miss D. Wardman, Assistant Personnel Officer, Searle Research & Development, Lane End Road, High Wycombe, Bucks (Tel. High Wycombe 21124 ext. 3254). 3884(A)

SEARLE

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

THE JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

RESEARCH FELLOW — DEPARTMENT OF BIOCHEMISTRY

The successful applicant will hold a PhD or have equivalent experience, and will be required to undertake research on the mechanism of enzyme reaction within a group headed by Dr J F Morrison. Current projects are concerned with the chemical mechanism of the reaction catalyzed by chorismate mutase-prephenate dehydrogenase, the slow-tight-binding inhibition of dihydrofolate reductase by folate analogues and the inhibition of phosphotransferases by lanthanide-nucleotide complexes. Applicants should have had postdoctoral experience in enzymology and possess expertise in kinetic and other procedures for studying enzymic catalysis.

The appointee should be able to commence duty in the first half of 1980.

CLOSING DATE: *31 JANUARY 1980.*

RESEARCH FELLOW — DEPARTMENT OF PHYSICAL BIOCHEMISTRY

Applicants should hold a PhD or have equivalent experience and be interested in joining a group engaged in one of the following fields of research: the physical and chemical characterization of biological macromolecules, interacting protein systems including studies on subunit assembly, self-associations and acceptor-ligand binding (Professor L W Nichol and Dr P J Jeffrey); studies of protein hydration and denaturation primarily involving calorimetric and spectroscopic methods (Dr H A McKenzie); comparative studies of sequences and properties of transferrins, lactoferrins, a-lactalbumins and lysozymes (Dr H A McKenzie and Dr D C Shaw). Further information may be obtained from Professor L W Nichol (Head of Department), in the University.

The appointee should be able to commence duty in the first half of 1980.

CLOSING DATE: *31 JANUARY 1980.*

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES POSTDOCTORAL FELLOW — DEPARTMENTS OF DEVELOPMENTAL BIOLOGY AND GENETICS

The Departments are undertaking a joint program on the role of phytohormones in the *Rhizobium*-legume symbiosis. The successful applicant will work with Dr D S Letham and associates on the determination of the phytohormones produced by different *Rhizobium* mutants and with Drs J Shine and B Rolfe on the cloning of genes responsible for their synthesis. Preference will be given to applicants with experience in biochemistry and/or molecular biology. Skill in the handling of bacteria would be an advantage.

CLOSING DATE: *30 JANUARY 1980.*

POSTDOCTORAL FELLOW — DEPARTMENT OF NEUROBIOLOGY

The successful applicant will be familiar with immunocyto-chemical techniques for the ultrastructure localisation of cytoskeletal proteins, and will pursue research on the architecture of the photoreceptor microvilli of arthropods in collaboration with Dr A D Blest. Interaction with studies of plant cyto-architecture directed by Professor B E S Gunning is also anticipated.

CLOSING DATE: *15 JANUARY 1980.*

SALARIES: Salary on appointment will be in accordance with qualifications and experience as follows: Research Fellow $A16,291-$21,265; Postdoctoral Fellow: a fixed point between $A16,291-$21,265 per annum. Present exchange rate: $A1: UK.52p.

TERM OF APPOINTMENT: Research Fellow, John Curtin School of Medical Research — two years, but in exceptional circumstances, three years with possible extension to five years. Postdoctoral Fellow — one to two years, although persons from overseas are not normally appointed for less than two years.

OTHER CONDITIONS: Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should first obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 3890(A)

UNIVERSITY OF OXFORD
DEPARTMENT OF ZOOLOGY

DEPARTMENTAL DEMONSTRATORSHIPS IN ZOOLOGY

Applications are invited for two Posts of Departmental Demonstrator in Zoology, with special reference to Vertebrate Zoology and Animal Behaviour. The persons appointed would be expected to take up their posts by October 1980. The successful candidates, who should have recently completed a Degree of Doctor of Philosophy or be in the final year before submission, will be required to take part in Zoology teaching and to undertake research in Zoology.

The appointments will be for three years in the first instance, with the possibility of renewal for a maximum of a further three years. The salary (subject to review) will be within the University Scale £3,775 to £5,199 per annum, with membership of USS.

Applications, with the names of two referees, should be submitted to the Head of Department, Department of Zoology, South Park Road, Oxford, OX1 3PS, by 10th January 1980. 3893(A)

POLYTECHNIC OF THE SOUTH BANK

DEPARTMENT OF ELECTRICAL ELECTRONIC ENGINEERING

RESEARCH ASSISTANT

Required to work on the development of the new design methods for Analogue/Digital Electronic Filters.

Salary £3,321 to £3,705 (inclusive of Inner London Allowance). Enquiries to Dr J K Stevenson (01-928 8989 Ext 2273).

Further particulars and application forms from the Staffing Officer, Polytechnic of the South Bank, Borough Road, London SE1 0AA. 3860(A)

POSTDOCTORAL POSITIO starting January 1980 to study molecul biology of mammalian mitochondri DNA. Experience in recombinant DN cloning and DNA sequencing is desirab but not necessary. Send curriculum vitae, brief summary of past research and nam of references to either Dr. P. J. Laipis Dr. W. W. Hauswirth, Department Biochemistry and Molecular Biology, Bo J-245, JHMHC, University of Florid Gainesville, Florida 32610. *Equ Employment Opportunity/Affirmati Action Employer* W605(

UNIVERSITY OF DUBLIN Trinity College

UNIVERSITY CHAIR OF BOTANY (1711)

This Chair will fall vacant on 1st October 1980, when Professor W A Watts, at his own request, transfers to a Personal Chair.
Further particulars of the post may be obtained from:

Mr G H H Giltrap
Secretary to the College
West Theatre
Trinity College
Dublin 2
Tel. 772941, Ext. 1123

to whom completed applications should be sent preferably by *Friday, 25th January 1980.* 3888(A)

UNIVERSITY OF REGINA

DEPARTMENT OF BIOLOGY

Applications are invited for the post of

RESEARCH STUDENT (MA or PhD)

the area of genetics of grasshoppers ntrol and populational aspects). Support funds available. Applications, luding curriculum vitae and names of references should be addresed to W Chapco, Dept. of Biology, iversity of Regina, Regina, katchewan, Canada S4S 0A2. W602(A)

JERRY LEWIS MUSCLE RESEARCH CENTRE

POST-DOCTORAL RESEARCH FELLOW

ired to work in collaboration with David Shotton, Department of hemistry, Imperial College, London, freeze fracture investigations of rophic human muscle. Previous rience in muscle research and electron oscopy desirable. Post tenable for 3 s, funded by the Wellcome Trust. ting salary £5,488 plus £740 London wance per annum.
pplications, with a curriculum vitae, a statement of research interests and rience, and names and addresses of 2 rees, to Professor V Dubowitz, rtment of Paediatrics and Neonatal icine, Institute of Child Health, mersmith Hospital, Du Cane Road, lon, W120HS. 3892(A)

UNIVERSITY OF CAPE TOWN

LECTURESHIP IN ORGANIC CHEMISTRY

ications are invited for the above post, nt as from 1st July 1980. ointment, according to qualifications xperience, will be made on the salary R8 100 × 450 — 9000 × 600 — R13200 nnum.
plicants should submit a curriculum stating present salary, research sts and publications, the date duty be assumed, and the names and sses of three referees.
moranda concerning the position and l conditions of service should be ed from the Registrar, Room 10, rsity of Cape Town, Private Bag, bosch 7700, by whom applications e received not later than 31 March W592(A)

WASHINGTON UNIVERSITY

School of Medicine

DEPARTMENT OF MEDICINE

Applications are invited for a

POSTDOCTORAL ASSOCIATE

to work on the biosynthesis of pancreatic islet polypeptide hormones. Experience in protein or nucleic acid chemistry is highly desirable. Salary approximately $15,000.

Applications, including a full c.v. and the names of two academic referees should be sent to Dr. Alan Permutt, Department of Medicine, Washington University School of Medicine, 660 S. Euclid, St. Louis, Missouri 63110, USA. W593(A)

McGILL UNIVERSITY

POSTDOCTORAL POSITION: CELL BIOLOGY

Applications are invited for a postdoctoral position for 2 years. The post is for research in the regulation of DNA replication and functions of tumor antigens in mammalian cells. It is available April 1, 1980. Previous experience in cell culture is required and training in molecular biology, animal virology or somatic cell genetics would be helpful. The research group includes other postdoctoral fellows and graduate students. Opportunities are available for interaction with other groups interested in nucleic acid research.

Applications with curriculum vitae and names of reference to: Dr Roger Hand, McGill Cancer Centre, 3655 Drummond, Montreal, Que. H3G 1Y6. W575(A)

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

LECTURER: MOLECULAR GENETICS

Applications are invited for the post of Lecturer, in Molecular Genetics, in The School of Biological Sciences. Applicants should have research interests in molecular genetics and experience in modern methods of gene manipulation and DNA biochemistry. The salary will be within the scale £4,333 to £8,992 (under review) with superannuation benefits.

Application forms and further particulars can be obtained from the Assistant Secretary of Science, Science Office (E), Sussex House, University of Sussex, Falmer, Brighton BN1 9RH, to whom applications (8 copies) should be sent by 14th January 1980. 3822(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Forest Research Kelmscott Western Australia

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

FIELD: Plant Pathology

DUTIES: The appointee will be part of a team of CSIRO and Western Australia Forest Department scientists who are studying eucalypt dieback in the native jarrah forests. Research will be primarily directed toward an understanding of those factors of the soil environment which affect disease incidence.

QUALIFICATIONS: Applicants should possess a PhD or equivalent and have research experience in soil-borne plant diseases or soil microbial ecology.

TENURE: Up to three years with a possibility of further extension. Superannuation benefits available.

SALARY: Research Scientist/Senior Research Scientist: A$15,916 — A$23,122 pa.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 1050/138 should reach:-

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 5th January 1980.

Applications in USA and Canada should be sent to:- The Counsellor Scientific, Embassy of Australia, 1610 Massachusets Avenue, N.W., Washington, D.C., 20036, USA. 3896(A)

THE CHINESE UNIVERSITY OF HONG KONG

FACULTY of MEDICINE

Applications are invited for the following post:

DIRECTOR OF THE ANIMAL HOUSE

tenable at this new medical school. The Animal House of the Faculty of Medicine will ultimately become the Main University Animal House.

Qualifications

Applicants should be qualified veterinary surgeons, preferably with relevant experience in the management of animal house in academic/research institutions.

Date of Assumption of Duty

The appointee is expected to assume duty by 1st January 1981 to supervise installation of facilities. Teaching in this Faculty will commence in the fall term of 1981.

Conditions of Service

Salary: HK$105,540 — 141,780 per annum by 8 increments. (Exchange rate approximately £1 = HK$10.8) Terms of service include long leave, superannuation benefits (University 15%, appointee 5%), medical and housing benefits and for overseas appointees, passage benefit as well.

Application Procedure

Application forms and further information on the Faculty and the scope of the job are obtainable from the Personnel Section, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong. Closing date of application is *31st March, 1980.* W603(A)

KUWAIT

UNIVERSITY OF KUWAIT FACULTY OF MEDICINE
MEDICAL SCIENCE AND CLINICAL APPOINTMENTS

Applications are invited for the following appointments in the Faculty of Medicine:-

ANATOMY

Associate professor. Candidates should have areas of specialisation in electron microscopy. The successful candidate's responsibilities will include directorship of the E.M. Unit which is equipped with scanning and transmission microscopes.

Assistant or associate professor. Preference will be given to candidates who have experience in teaching the anatomical disciplines to allied health students. The successful candidate will be responsible for coordinating allied health teaching in the Department of Anatomy.

COMMUNITY MEDICINE

Assistant or associate professor in epidemiology (2 posts).

Assistant or associate professor in public health.

Preference for these posts will be given to suitable candidates who speak Arabic.

MEDICINE

Associate professor in nephrology.

Associate professor in neurology.

OBSTETRICS AND GYNAECOLOGY

Associate professor or professor, and assistant professor (2 posts).

Assistant professor or associate professor. Scientist gynaecologist conversant with the practical aspects of gynaecologic endocrinology and hormone assay. A biochemist with extensive experience in these areas may apply and, if appointed, would also be expected to undertake some teaching in the Department of Biochemistry.

PATHOLOGY

Assistant and associate professors (2 posts). Candidates should have experience in academic pathology, particularly in anatomic and histopathology. The successful candidates will have responsibilities in diagnostic pathology at the teaching hospital.

PHARMACOLOGY

Professor. Candidates should be medically qualified.

PHYSIOLOGY

Associate professor or professor in neurophysiology.

Assistant or associate professor in general physiology. Preference will be given to candidates with specialisation in one of the following areas: cardiovascular, gastro-intestinal, muscle physiology, haematology.

PSYCHIATRY

Associate professor or professor. Preference will be given to suitable candidates who speak Arabic.

SURGERY

Associate professor or professor in orthopaedic surgery.

Associate professor in E.N.T. surgery.

Assistant or associate professor in plastic, reconstructive and burn surgery.

Assistant or associate professor in general surgery with special interest in traumatology.

Assistant professor in surgical research.

Applicants for surgical posts should have at least 5 years clinical and teaching experience in their respective specialties.

Conditions of appointment

Applicants should possess a PhD, or higher professional qualification in their respective medical or surgical specialty, and have conducted and published research in their field. Professors should have 14 years' experience, 4 as an associate professor or its equivalent, i.e. senior lecturer or reader. Associate professors should have 9 years' experience, 4 as an assistant professor or its equivalent i.e. lecturer.

Salaries: Total monthly salaries will be within the following scales according to qualifications and experience (1KD = £1.60; US$3.6 approx.).
Professors with clinical appointments: KD 880-1045 (8 increments).
Professors medically or non-medically qualified with medical science appointments: KD 826-982 (8 increments).
Associate professors with clinical appointments:
KD 725-890 (8 increments).
Associate professors medically qualified with medical science appointments: KD 680-836 (8 increments).
Associate professors non-medically qualified: KD 650-800 (8 increments).
Assistant professors with clinical appointments:
KD 570-735 (8 increments).
Assistant professors medically qualified with medical science appointments: KD 534-690 (8 increments).
Assistant professors non-medically qualified: KD 510-660 (8 increments).

Clinical supplements: In addition to the above university salaries there will be a monthly clinical supplement paid by the Ministry of Public Health for medical school staff with clinical service commitments. These are:

Professor and chairman	— KD 250
Professor	— KD 200
Associate professor	— KD 150
Assistant professor	— KD 100

Gratuity: There is a gratuity of one month's basic salary for each year employed payable on termination of contract.

Housing: Suitably furnished, air-conditioned accommodation, electricity and water are provided free of charge.

Medical care: Free, comprehensive treatment is available in Kuwait under the State Health Service.

Travel: Air tickets are provided from the country of recruitment for the appointee, spouse and up to 3 dependent children under 20 years. Thereafter return air tickets are issued annually to the country of citizenship or permanent residence. On termination of contract, tickets are provided to the country of recruitment. A baggage and freight allowance is also provided. In addition, travel expenses for attending one scientific meeting a year are paid by the University.

Vacation: Sixty days paid annual leave and various official holidays.

Education: this is provided free in state schools where the instruction is in Arabic. Staff who have to send their children to non-Arabic schools in Kuwait will have the tuition fees of up to a maximum of three met by the University.

Taxation: There is no income tax in Kuwait. Currency is freely transferable without restriction.

Method of application

Curriculum vitae in duplicate, which should include the names of three referees, personal particulars, qualifications with dates, career history, teaching experience, research accomplishments and, where appropriate, clinical experience should be sent to the Dean, Faculty of Medicine, University of Kuwait, P.O. Box 24923 Safat, Kuwait to arrive no later than 31st January 1980. W604(A)

CANCER RESEARCH UNIT, University of Western Ontario, London, Ontario. Positions are available for staff at the Assistant or Associate Professor level (non-tenure track) and for postdoctoral fellows and graduate students. Research is focussed on the areas of cellular and viral DNA replication, nucleic acid metabolism in eukaryotic cells, mRNA cloning, and mechanisms of cell transformation.

The unit is well funded by the National Cancer Institute of Canada and is affiliated with the Department of Biochemistry and the Department of Microbiology and Immunology in the Medical School of the University.

Candidates for a staff position should submit a curriculum vitae, statement of research interests, and the names of three referees to Dr. David T. Denhardt, c/o The Administrative Secretary, Cancer Research Unit, University of Western Ontario, London, Ontario N6A 5B7, Canada. Students should apply for admission through the above mentioned Departments. W[illegible]

MEDICAL LABORATORY SCIENTIFIC Officer, associate IMLS or equivalent, experience in radioimmunoassay techniques an advantage. Appointment is for three years. Salary in the range £4122 to £4620 depending on experience. Applications giving the names of two referees to Professor L P Le Quesne, Department of Surgical Studies, The Middlesex Hospital Medical School, Mortimer Street, London W1N 8AA. 3877(A)

BIOZYME LABORATORIES LTD
Unit 6, Gilchrist-Thomas Estate,
Blaenavon,
Gwent NP4 9RL

MANUFACTURERS OF ENZYMES AND RELATED BIOCHEMICALS

require

(1) PRODUCTION CHEMISTS

and

(2) PRODUCTION CHEMICAL TECHNICIANS

To be employed to carry out varied and interesting work in the Production and Analytical Department.

Experience, though helpful, is not essential, but minimum qualifications should be
(1) BSc or equivalent with Chemistry as major subject
(2) 'A' Level or equivalent in Chemistry.

Training will be given to suitable applicants in the various departments and the positions carry excellent promotional prospects.

Please apply for application form. 3894(A)

ELECTROPHYSIOLOGIST BIOPHYSICIST research associate t study membrane currents under voltag clamp in dialyzed and intact neurones Emphasis on mechanisms of chemica modulation of conductances. Applicant should have relevant training plus goo physical background, preferably wit digital computer experience. Appointmen for two years or more to begin as soon a possible. Send CV and names of tw referees to Dr R Eckert, Department c Biology, University of California, L Angeles, CA 90024. Equal Opportunity Affirmative Action Employer. W596(A)

INSTITUTE OF CANCER RESEARCH

ULTRASONIC IMAGE ANALYSIS IN CANCER INVESTIGATION

A PHYSICAL SCIENTIST

is required to help co-ordinate the work an active, multi-disciplinary team applying pattern recognition and ima analysis techniques to the extraction diagnostic information from ultrason B-scan images. The work forms part of larger research programme in ultrasour jointly organised between Physics ar Clinical Diagnostic groups at the Institu of Cancer Research and Royal Marsde Hospital, Sutton, Surrey, and the prese project involves collaboration with thr other major laboratories in the fields ultrasonic imaging and data analysis.

Candidates should preferably ha experience in ultrasound or image analys methods and should hold a PhD in appropriate field, or be able demonstrate a comparable level of attai ment. The appointment will be for thr years in the first instance.

Salary will be on MRC Scientist scal (grade II, non-clinical) commencing at point in the range £4,333 p.a. to £5,777 p. depending on qualifications ar experience. In addition London Allowan of £740 p.a. is payable, and the post carri superannuation under the USS pensi scheme.

Applications with full curriculum vi in duplicate and the names and addresses two professional referees should be sent the Secretary, Institute of Canc Research, 34 Sumner Place, London, S 3NU, quoting ref. 300/B/20 3901(A)

Southampton THE UNIVERSITY

OCEANOGRAPHY DEPARTMENT

A RESEARCH ASSISTANT

is required by the Department of Oceanography, Southampton University, for a one year project to investigate applications of LANDSAT imagery in oceanography. Applicants must have a degree in physical/chemical oceanography and be experienced in the interpretation and enhancement of LANDSAT imagery.

Salary on scale 1B from £3775 per annum.

Applications giving date of birth, brief curriculum vitae and the names of two referees to Mrs E C P Sears, Staffing Department, The University, Highfield, Southampton SO9 5NH, within one week of the appearance of this advertisement. Please quote reference number 1904/R/N. 3868(A)

BRIGHTON POLYTECHNIC
DEPARTMENT OF PHARMACY
POST-DOCTORAL RESEARCH FELLOW

A post funded by the Medical Research Council is available for a research fellow to carry out a biophysical study of cervical mucus thickening. The post would suit persons holding higher degrees in pharmacy, biochemistry, biophysics or any other related subject.

Appointments will be made on an annual basis up to a maximum of three years and the initial salary will be £4,083 (+£72 per annum pending comparability study).

Applications, in the form of a letter, together with a curriculum vitae and the names of two referees, should be made by 31 January 1980 to the supervisor, Dr C Marriott, Department of Pharmacy, Brighton Polytechnic, Moulsecoomb, Brighton BN2 4GJ, Tel Brighton 693655 Ext 2213. 3891(A)

MEDICAL RESEARCH COUNCIL
LABORATORY OF MOLECULAR BIOLOGY

pplications are invited for a scientific pointment, available from September, 80.

The post is a permanent one and plicants must have had extensive earch experience and accomplishment in e field of the immunobiology of haema-oeisis.

Salary scale £8,698 to £10,775.

Applications, with full c.v. and names of o referees, should be sent to The ministrative Secretary, Laboratory of olecular Biology, The Medical School, ls Road, Cambridge CB2 2QH. 3881(A)

UNIVERSITY OF LONDON
KING'S COLLEGE
BIOCHEMIST OR PHARMACOLOGIST

search Assistant required at tgraduate or postdoctoral level to work mechanism of action of nicotine-like gs. Appointment at appropriate ition on University scale.

nowledge of membrane or lipid chemistry an advantage.

lease apply in writing to Dr J M leton, Department of Pharmacology, g's College, London WC2R 2LS. 3817(A)

BIOGEN S.A.

a young company engaged in basic and applied research in the field of molecular biology and microbiology, and with the objective of utilizing the potential of genetic engineering for the production of substances of commercial and medical interest in such areas as health care, agriculture and energy, is inviting applications for its **Research Laboratory in Geneva**, Switzerland:

RESEARCH MANAGER, for a person of

- outstanding scientific level in the field of molecular biology and microbiology,
- with proven ability in the coordination and administration of the activities of a research laboratory,
- sense of human relations, as well as capacity for organization, are required.

NUCLEIC ACID CHEMIST

with good experience in recent technologies for the synthesis of DNA.

In both cases, salary (including fringe benefits) will be competitive and in accordance with competence and experience. Send curriculum vitae (with a description of previous experience and a list of publications) to BIOGEN Laboratory, 3 Route de Troinex, 1227 Geneva, Switzerland. W590(A)

UNIVERSITY OF NEWCASTLE UPON TYNE
THE MEDICAL SCHOOL
LECTURESHIP IN ANATOMY

Applications are invited from registered medical practitioners or other suitably qualified candidates for the post of Lecturer in Anatomy to be filled as soon as possible. The Lecturer will be expected to devote the whole of his/her time to teaching and research work in the Department of Anatomy. There are good facilities for research in the Department, including developmental cell biology, immunology, neurophysiology, kinaesiology, neuroanatomy, general histology and electron microscopy.

Some preference would be given to a candidate whose research interest lies within developmental cell biology and/or immunology and who has experience of teaching gross anatomy.

Salary will be at an appropriate point on one of the following scales according to age, qualifications and experience: Lecturers' Non-Medical £4,333 to £8,992 per annum; Lecturers' Pre-Clinical General £5,777 to £8,992 per annum; Lecturers' Pre-Clinical Higher £8,404 to £9,581 per annum. Membership of the appropriate University Superannuation Scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar (FP), The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU with whom applications (3 copies) together with the names and addresses of 3 referees, should be lodged not later than 2nd January, 1980. Please quote reference N. 3870(A)

BRITISH POSTGRADUATE MEDICAL FEDERATION
(University of London)

CARDIOTHORACIC INSTITUTE
(Associated with National Heart and Chest Hospitals)

NON-CLINICAL SENIOR LECTURER IN CARDIAC MUSCLE RESEARCH UNIT

A vacancy occurs for a non-clinical Senior Lecturer in the Department of Cardiac Medicine at 50 Wimpole Street, London W.1. The Department has an active research unit in myocardial metabolism, with a team of 15 graduates and programmes in: ion transport, mitochondrial, plasmalemmal and sarcoplasmic reticulum function, electrophysiology, adrenergic receptors, ultrastructure, and the pathophysiology of hypoxia, ischaemia and experimental cardiomyopathy.

The successful candidate would be expected to contribute to or widen the activities of the Unit and to take an important share in the direction of the research. Applications are invited from scientists with a well-established interest in the fields of myocardial biology, biochemistry, physiology or pharmacology.

Salary will be on an appropriate point on the non-clinical Senior Lecturer scale, currently £8,698 to £10,775 + £740 London Allowance. The post is superannuable in the USS.

For further information please contact the Head of the Department, Professor Peter Harris, telephone 01-486 3043, who will be glad to discuss the nature of the appointment.

Formal applications, in duplicate, including curriculum vitae, list of publications and names of three referees, should reach the Secretary, Cardiothoracic Institute, Fulham Road, Brompton, London SW3 6HP not later than 11th January 1980. 3900(A)

European Molecular Biology Laboratory

INSTRUMENTATION DIVISION

The Instrumentation Division of the EMBL is responsible for the development and implementation of advanced instrumentation and experimental techniques in the fundamental biological sciences. Applications are invited from suitably qualified and experienced applicants to fill the following vacancies at the new EMBL Laboratory in Heidelberg, Federal Republic of Germany.

NUMERICAL DATA ANALYSIS
Mathematician/Programmer (Ref. 79/14)

to develop new algorithms in such areas as image processing, large-scale constraint optimisation and statistical data analysis, X-ray diffraction; also to implement the algorithms in portable user-oriented programs.

CHEMICAL INSTRUMENTATION
Research Assistant (Ref.: 79/17)

to design, develop and adapt laboratory instrumentation for new instrumental techniques (eg stopped-flow kinetics, sequence analysis etc.). This work will be carried out in close collaboration with one or more of the biological groups which are active in these areas.

ELECTRON MICROSCOPY
Physicist (Ref.: 79/24)
Technical Assistant (Ref. 79/25)

The EM Development Group is responsible for the design and construction of two new electron microscopes as well as the development of techniques and ancilliary equipment for the existing microscopes at EMBL. The successful applicants for the above posts will take part in one or more aspects of these activities.

The initial contract offered to successful applicants will be of three years' duration. The salary offered will be between DM3000 and DM4000 for the mathematician/programmer, research assistant and physicist and between DM2600 and DM3300 for the technical assistant post. The monthly salaries quoted are net of tax and will be augmented by allowances for expatriation and family, depending on individual circumstances.

Please apply briefly to:

EMBL, Personnel Section, Postfach 10.2209, D — 6900 Heidelberg, Federal Republic of Germany, for an application form, **quoting the reference number** of the post which interests you. W588(A)

SCIENTIFIC & MEDICAL PUBLISHING

EDITORIAL SERVICES & PRODUCTION CONTROLLER

Macmillan Scientific and Medical Division, based in Basingstoke, publishes both books and journals in high-level sciences and medicine.

A new position has been created within the division for a person to handle the book publishing programme from receipt of manuscripts to production of printed copies.

The work involves close liaison with top academic authors, organisation of the editing process and regular contact with printers. Applicants should be familiar with copy-editing, proof reading and the preparation of artwork and an appreciation of modern printing techniques is desirable. A god command of English, a concern for detail and the ability to work under pressure are essential. A scientific or medical background would be helpful.

Applications are invited from candidates with relevant publishing experience. This is a senior position within the division and commands a competitive salary and attractive benefits.

Please write for full details to Sheilagh Browne, Macmillan Publishers Limited, Bruenl Road, Basingstoke, RG21 2XS. 3898(A)

APPLICATIONS ARE INVITED FOR the position of chairman of the computer science department at Concordia University. The department has over 20 faculty members and a number of system analysts. It offers programmes at both the undergraduate and graduate levels. At the undergraduate level it offers a Batchelor of Computer Science Programme with options in General Science, Digital Systems, General Businees and Mathematics and an Honours programme in Computer Science. There are over 625 undergraduate students, and 120 graduate students, full-time and part-time. The language of instruction is English. Interested candidates may send a curriculum vitae along with the names of three referees to: Prof M N S Swamy, Dean of Engineering, Concordia University, 1455 de Maisonneuve Blvd. West, Montreal, Quebec, Canada, H3G 1M8 W599(A)

THE POLYTECHNIC OF CENTRAL LONDON

SCHOOL OF ENGINEERING AND SCIENCE

MICROBIOLOGY TECHNICIAN GRADE 5

Salary: £4,224 to £4,845 increasing to £4,452 to £5,109 at 1 April 1980. These figures include £525 London Allowance.

Work involves organisation and daily running of Microbiology Teaching Laboratories, preparation of Media, upkeep of stock cultures, maintenance and operation of equipment. Applicants should have a sound knowledge of Microbiology.

The following qualifications are required: HNC, HND, C&G Part III with 8-9 years experience (inclusive of training) or the equivalent and/or appropriate industrial experience.

Application form and job description from the Establishment Officer, PCL, 309 Regent Street, London W1R 8AL (Tel: 01-580-2020 ext. 212). 3872(A)

DALHOUSIE UNIVERSITY

CITY OF LONDON POLYTECHNIC
DEPARTMENT OF BIOLOGICAL SCIENCES
GRADUATE RESEARCH ASSISTANT

A graduate technical officer is required immediately to work on a World Health Organisation sponsored study of plant substances as fertility regulating agents. The project will be of interest to pharmacologists and reproductive physiologists. Experience with small mammals will be an asset. The successful applicant may be able to register for a higher degree.

Salary commencing at £3,417 including London Weighting. A full curriculum vitae giving the names and addresses of two referees should be sent to Dr J P G Williams, Department of Biological Sciences, Old Castle Street, London E1 7NT within two weeks of the appearance of this advertisement. 3864(A)

FREIE UNIVERSITÄT BERLIN
INSTITUT FÜR NEUROPSYCHOPHARMAKOLOGIE
POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for appointment from 1 February 1980 to join a research team investigating various aspects of the neurochemistry of 5-hydroxytryptamine metabolism. Experience in receptor binding would be advantageous. The post will be for two years with possibility of renewal. The salary will be according to BAT IIa (about 42,000 to 45,000 DM pa).

Applicants should write, enclosing full curriculum vitae, to: Dr. H. Rommelspacher, Institut für Neuropsychopharmakologie der Freien Universität Berlin, Ulmenallee 30, D-1000 Berlin 19, West Germany (Tel: 030-3003239). W591(A)

HARVARD UNIVERSITY
SCHOOL OF PUBLIC HEALTH
RESPIRATORY PHYSIOLOGIST

Applications are invited for the position of Assistant Professor of Respiratory Physiology. Successful candidate will join group of basic and applied scientists in the field of respiratory mechanics. Research mainly in chest wall mechanics, actions of respiratory muscles, and mechanical factors in the control of breathing in animals and humans; collaboration with groups studying lung defense mechanisms, occupational and environmental health, and adult and pediatric chest medicine. Good background in math and physics with several years' postdoctoral research experience in respiratory physiology required.

Interested applicants should forward curriculum vitae, three letters of recommendation, and selected reprints to: Jere Mead, MD, Professor, Department of Physiology, Harvard School of Public Health, 665 Huntington Avenue, Boston, MA 02115.

Harvard is an Equal Opportunity/ Affirmative Action Employer. W586(A)

UNIVERSITY OF EDINBURGH
SENIOR LECTURER/ LECTURER IN PHYSIOLOGY

Tenable from 1st January 1980.

Salary on the scale £8,698 to £10,775 for Senior Lecturers, or £4,333 to £8,992 for Lecturers.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications (6 copies) together with curriculum vitae and the names and addresses of three referees should be lodged not later than 8th January 1980.

Please quote ref no 519. 3871(A)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF PHARMACOLOGY
Applications are invited for a RESEARCH ASSOCIATE OR SENIOR RESEARCH ASSOCIATE

to work on an MRC-funded project involving analysis of stimulus-secretion coupling in pancreatic cells by laser light scattering techniques. The appointment is tenable for up to two years and salary will be in the range £5,199 to £6,932, or £6,066 to £8,892, according to qualifications and experience, with U.S.S. A biophysical background or experience in computing and photon correlation spectroscopy would be advantageous but applicants with a PhD in Physics and an interest in its biological applications would also be welcomed.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to, Dr E K Matthews, University Reader in Pharmacology, Department of Pharmacology, University of Cambridge, Hills Road, Cambridge CB2 2QD. 3873(A)

BASIC GRADE BIOCHEMIST

required for the remaining five months of a hospital grant to measure plasma catechol amines by a working radio enzyme method starting on 7.1.80. Salary on scale £4,205 — £5,714 inc.

Application forms obtainable from Department of Personnel, University College Hospital, Gower Street, WC1E 6AU. Tel: 387 9300 Ext. 381. 3904(A)

METABOLISM AND PHARMACOKINETICS

Experienced in the respiratory field? Interested in Deposition of drugs in the Lungs?

A vacancy has arisen in our Metobolic Studies Department for a person to lead a small team concerned with the deposition and absorption of medicinal aerosols in the lungs. Ideally we are interested in someone with a sound knowledge of human and animal respitory systems, both structure and function, who have an interest in Pharmacokinetics. The particular concern of the department is in the dosimetry and site of deposition of potential aerosol products but an interest in fundamental principles involved in this area will be encouraged.

Suitable candidates will probably have 1-3 years post-doctoral experience in the appropriate field of interest or have a good degree and equivalent experience.

The position carries a competitive salary which will reflect the experience of the successful candidate.

Filsons offer attractive working conditions in a pleasant part of the country. Other benefits including flexible working hours, annual bonus, an active sport and social club and assistance with relocation where appropriate.

Applicants, male or female should telephone or write for an application form to Cathy Mason, Personnel Officer, Fisons Ltd, Pharmaceutical Division, Bakewell Road, Loughborough, Leics. Tel: 0509 66361.

Public Health Laboratory Service

Communicable Disease Surveillance Centre

Technical Editor

The Communicable Disease Surveillance Centre of the Public Health Laboratory Service requires a technical editor, deputy to the medical editor, for the weekly Communicable Disease Report and other communicable disease surveillance reports. Candidates must be university science graduates with experience in the National Health Service and be fully conversant with clinical and microbiological terminology. Clinical and or microbiological experience an advantage.

Salary scale: The appointment will be on NHS terms and conditions and the salary scale will be within the range £5935 to £8083 (including London Weighting Allowance).

A job description and application form can be obtained from Mr A Collins, Centre Administrator, Communicable Disease Surveillance Centre, 61 Colindale Avenue, London NW9 5EQ. Tel. 01-200 6868. Closing date: 31 December 1979.

PHLS

UNIVERSITY OF ESSEX

POST-DOCTORAL MICROBIAL ECOLOGIST

Applications are invited for a NERC post-doctoral Fellowship, to work in the Department of Biology with Dr D B Nedwell. The project is intended to develop methods for measuring turnover of selected organic molecules in anaerobic saltmarsh sediments in order to elucidate patterns of carbon flow in the microbial community. The programme will involve field work and laboratory work on model systems. Experience with gas chromatography, radiotracers and continuous culture would be advantageous. The appointment commences as soon as possible for three years, and salary will be at the appropriate point on the Range IA scale (£4333 to £7521).

Applications (two copies) including a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to the Registrar (AG/95/N) University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained. 3875(A)

INSTITUTE OF CANCER RESEARCH

ULTRASOUND IN CANCER DIAGNOSIS

A RESEARCH TECHNICIAN (Physical sciences)

is required to join a multi-disciplinary research group working on Ultrasonic imaging and analytical methods in cancer investigation. This job, which is likely to include assisting in ultrasonic examination of patients and subsequent computer analysis of data, will be based at the Royal Marsden Hospital, Sutton, Surrey.

Candidates should have had training, and preferably some experience, in a physical science or in radiography and should have obtained HNC, BSc or an equivalent qualification in an appropriate subject.

Salary will be on MRC scales commencing at a point in the range £3,768 p.a. to £4,008 p.a. Applications with full curriculum vitae in duplicate and the names and addresses of two professional referees should be sent to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/88. 3902(A)

ASSOCIATESHIPS

QUEEN'S UNIVERSITY AT KINGSTON

DEPARTMENT OF PHYSICS

RESEARCH ASSOCIATESHIP

Applications are invited for a post-doctoral research appointment involving the development of solid state hydrogen ion conductors and the physics of fast ion transport. The appointment is for an initial period of one year renewable for a second year.

Salary $14,500 — $15,000 depending upon qualifications. Please apply including the names of two referees to: Dr M Sayer, Department of Physics, Queen's University, Kingston, Ont., Canada K7L 3N6 W600(O)

CONFERENCES

CONFERENCE RECEPTOR MEDIATED BINDING AND INTERNALIZATION OF TOXINS AND HORMONES

Conference sponsored by US Army Medical Research Institute for Infectious Diseases to be held at Frederick, Maryland on March 24-26, 1980. Program composed of talks by 25 international scientists expert in the areas of toxins and polypeptide hormones. Attendance will be limited by space to 130 scientists.

Further information may be obtained and application made by writing to Dr John L. Middlebrook, Pathology Division, USAMRIID, Fort Detrick, Frederick, Maryland 21701. W601(C)

ASSISTANTSHIPS

UNIVERSITY OF CALGARY

GRADUATE ASSISTANTSHIPS (Teaching and Research)

Available for students proceeding to the MSc and PhD degrees in all branches of Chemistry and Biochemistry. The assistantships are valued at $7,400 to $9,000 p.a. and include remission of program fees. Travel allowance also available.

For further information write to Department of Chemistry, Chairman of Graduate Studies, University of Calgary, Calgary, Alberta, Canada T2N 1N4. Please indicate field of interest. W579(P)

GRANTS and SCHOLARSHIPS

THE UNIVERSITY OF WESTERN AUSTRALIA Perth FORESTS DEPARTMENT POSTGRADUATE SCHOLARSHIP IN BOTANY

Applications for a Forests Department Postgraduate Scholarship in Botany are invited from graduates with a first-class upper division second-class honours degree in Botany, and Forestry or Agriculture graduates whose courses of study have extended over at least four years and who have had appropriate research experience. The Scholarships, financed by the Forests Department of Western Australia, will be tenable for up to three years. The value of the Scholarship is $4000 per annum. The student will be required to undertake research in a field covering aspects of physiology, ecology or mycology in relation to multiple use forestry, or such other fields as may be prescribed. Applicants are advised to obtain further information on possible fields of interest by writing to the Head of the Department of Botany.

Applications in triplicate stating personal particulars, academic record, research experience, etcetera should reach the Registrar, University of Western Australia, Nedlands, 6009, Western Australia, by *31st December, 19*. Candidates should request two academic referees to write immediately to the Registrar. 3889(H)

Leonardo Santi (Genova) and Giorgio Vidali (New York) Organizers
Michael Bustin (Bethesda) and Franco Celada (Genova) Scientific Committee

The invited speakers will include: H. Zachau (Munchen), M. Bustin (Bethesda) D. Stollar (Boston), M. Romani (New York), R. Gallo (Bethesda), H. Bautz (Heidelberg), J. Sommerville (Fife), T. Martin (Chicago), B.E. Erlanger (New York), H. Kunkel (New York), R. Lahita (New York), E.M. Tan (Denver), M. Reichlin (Buffalo), P.H. Lambert (Geneve), A. Marmont (Genova), S. Bombardieri (Pisa), G. Klein (Stockholm), R. Baserga (Philadelphia), L. Philipson (Uppsala), J.S. Pagano (Chapel Hill), L. Santi (Genova), M. Van Regenmortel (Strasbourg), M. Leng (Orleans), L. Zardi (Genova) M. Poirier (Bethesda).

The total number of participants will be limited to 50 and applications from young investigators are encouraged. Further details from Dr. Leonardo Santi, Instituto di Oncologia, Viale Benedetto XV 10, 16132 Genova, Italy and from Dr. Giorgio Vidali, The Rockefeller University, New York, N.Y. 10021, USA. Closing date for applications February 15, 1980. W587(D)

UNIVERSITY OF LONDON — KING'S COLLEGE
MSc IN HUMAN AND APPLIED PHYSIOLOGY

A one year full-time (or two year part-time*) course to train graduates in measuring and studying the physiological functioning of man in normal and abnormal environments. The course would equip students to specialise in the applications of physiology to man in industrial, Service and clinical situations and the teaching of human physiology. Topics studied include: basic measurements; life support systems; exercise; locomotor; postural; climatic; high altitude and hyperbaric physiology.

September 1980 to September 1981 (1982*).

Applicants should normally have a good degree in Physiology or be medically qualified.

Further details and application form from: Dr S Rowlands, King's College, Strand, London SC2R 2LS.

Closing date for applications: 31 March 1980. 3882(D)

FELLOWSHIPS

1980 BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Notice is hereby given that an election of Junior Beit Fellows to begin work on 1 October 1980 will take place in May 1980. Junior Fellowships carry an initial value of £4,333 to £5,199 plus £740 London Allowance, plus yearly increments for three years. There will be the usual university superannuation contributions and benefits. Candidates must have taken a degree in a faculty of a university approved by the Trustees in Her Majesty's Dominions, Protectorates and Mandated Territories, India, Pakistan, the Republic of Ireland and the United Kingdom, or a medical diploma registrable in the UK. Elections to Junior Fellowships are rarely made above the age of 35 years. Applications from candidates must submit evidence where they propose to work, which must be in Great Britain or Ireland.

Forms of application and all information may be obtained from Professor W G Spector, (Secretary), Pathology Department, St Bartholomew's Hospital, London EC1A 7BE. For Overseas candidates forms of application may be obtained from, The Secretary, South African Medical Council, PO Box 205, Pretoria, South Africa; The Ministry of Health, The Government of India, New Delhi, India; The Secretary, Department of Education and Science, PO Box 826, Canberra City, A C T 2601, Australia; The Department of Health, Wellington, New Zealand; and, The Canadian Medical Association, 1867 Alta Vista Drive, Ottawa 8, Ontario, Canada. 3863(E)

THE ROYAL SOCIETY
E.P.A. Cephalosporin Fund SENIOR RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for the E.P.A. Cephalosporin Fund Senior Research Fellowship, endowed by the Trustees of the E.P.A. Cephalosporin Fund to provide a research fellowship in the medical, biological and chemical sciences. On this occasion applications are restricted to those working in the field of biological chemistry. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from 1 October 1980 (or another date to be arranged) and may be renewable for one further five-year period. Applicants should preferably be under 40 on 1 October 1980. The stipend scale will be £9138 × £300 to £10 518 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and returned by 15 January 1980. 3859(E)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
POST-DOCTORAL FELLOWSHIP (MRC) IN HUMAN PHYSIOLOGY

A new group has been established in the Department of Physiology and Pharmacology under the leadership of Dr C T M Davies (MRC) to investigate the physiology and biochemistry of human muscle in the elderly.

Postgraduates with appropriate experience of physiology interested in this Fellowship should write in the first instance to Professor P H Fentem, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, enclosing a curriculum vitae and the names of two referees. 3869(E)

FOULKES FOUNDATION FELLOWSHIPS 1980

The Foulkes Foundation provides financial support for recently qualified science graduates with research experience who want to study medicine and for medical graduates who want to take a science degree. In both cases graduates must intend to do medical research after qualification.

Application forms and further information are available from: The Administrative Assistant, Foulkes Foundation Fellowships, The Ciba Foundation, 41 Portland Place, London W1N 4BN, enclosing a s.a.e. Closing date 31 March 1980. 3867(E)

UNIVERSITY OF NOTTINGHAM SCHOOL OF AGRICULTURE
DEPARTMENT OF PHYSIOLOGY & ENVIRONMENTAL STUDIES
POST-DOCTORAL FELLOWSHIPS IN REPRODUCTIVE PHYSIOLOGY

Two post-doctoral fellowships are available for 15 months to assist in established research projects in bovine reproduction concerning a) hormonal control of ovulation and b) embryonic mortality.

Applications are invited from agricultural science, biology or veterinary graduates. Experience in handling large mammals and using radioimmunoassay an advantage. Qualified predoctoral candidates will also be considered. Salary £4,333 to £4,910 p.a. (Pre-Doctoral £3,7[illegible] to £4,333).

Application forms and further details can be obtained from The Secretary, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. 3905(E)

THE LEITZ DIALUX 20 – TODAY'S MICROSCOPE FOR TOMORROW'S DEVELOPMENTS

The LEITZ DIALUX 20 has been designed with an eye to the future development of microscopy: the established Leitz modular principle has been extended as a result of current experience: it is now even more practical, and offers optimum operating convenience with maximum functional reliability.

A considerably improved arrangement of the optical illuminating system makes the LEITZ DIALUX 20 even more efficient for all optical examinations of transparent specimens. It has been possible to enlarge the microscope field of view even further through the use of the excellently corrected series of LEITZ NPL FLUOTAR objectives. Amounting to more than 23% when compared with that of conventional microscopes – with critical definition across the entire image, this ensures that the new LEITZ DIALUX 20 is not only a reliable tool for diagnostic microscopy, but also a basic instrument that has the necessary reserves for biological research. We should like to convince you of the extremely favourable relationship between performance and price.

☐ I should like to know more about the LEITZ DIALUX 20 and would be pleased to receive full details.
☐ I should like to arrange a date for the Leitz consultant to visit me.

E"E.'T E :. :IC OUTFIT POINTS THE WAY TO MAXIMUM MICROSCOPIC PERFORMANCE.

There are many valid reasons why research workers the world over decide in favour of a LEITZ ORTHOPLAN. The most important one is the LEITZ plan-apochromats, which produce images of unsurpassed resolution and edge-to-edge pin-sharpness. They also permit the utilization of a field of view which with large-field eyepieces is up to 140% larger than what has hitherto been possible to observe in a conventional microscope. This means more and better information at a glance, without the need to adjust the object.

There is not a single optical microscopic method of illumination and contrasting for which the LEITZ ORTHOPLAN cannot be adapted very quickly, to be instantly ready for any microscopic problem.

But the possibilities of the LEITZ ORTHOPLAN far exceed the field of classical microscopy.

They make this microscope the central optical component of all quantitative methods of microscope photometry with the LEITZ MPV system, and in electronic image analysis with the LEITZ T.A.S. the LEITZ consultant will be delighted to call on you and to demonstrate in your own laboratory

how the LEITZ ORTHOPLAN can solve your special microscopic problems. All you have to do is send us the coupon below.

☐ I should like to know more about the LEITZ ORTHOPLAN and would be grateful for your detailed prospectus.
☐ I should like to arrange a meeting with the LEITZ consultant soon.

Please send this coupon or simply write to:
Information Service Ernst Leitz Wetzlar GmbH 409
D-6330 WETZLAR/Germany,
or to your national Leitz Agency.

Leitz means precision. Worldwide.

Comparison of fields of view – only one of the many performance features of the LEITZ ORTHOPLAN:

In the conventional microscope: field-of-view index 18.

In the LEITZ ORTHOPLAN, field-of-view index 28.

Circle No. 06 on Reader Enquiry Card.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Project Kiwi One: an acoustic cross-section of the South Pacific Ocean	*D.G. Browning, R.W. Bannister, R.N.Denham and K.M. Guthrie*	820

INDEXES

Annual Indexes are available for the years 1971-1978. The year's papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

Registered No: 785998 England
Registered Office:
4 Little Essex Street
London WC2R 3LF

X-ray diffraction from the side-by-side model of DNA	*R.J. Greenall, W.J. Pigram and W. Fuller*	880
Errata		882

Your attention is drawn to contents page v on 6 December, which refers to several biological letters omitted from the contents page of 29 November.

BOOK REVIEWS

Plant Strategies and Vegetation Processes (J.P. Grime)	*P.D. Moore*	883
Cosmical Magnetic Fields (E.N. Parker)	*W.M. Glencross*	883
Social Insects (H.R. Hermann, editor)	*Eric L. Charnov*	884
Image Analysis, Enhancement and Interpretation (D.L. Missell); Computer Techniques for Image Processing in Electron Microscopy (W.O. Saxton)	*P.W. Hawkes*	885
Phytoplankton Manual (A. Sournia, editor)	*G.T. Boalch*	886

Announcements xvii

Newly on the market xix

The authorship of the article 'Crust of Oceanic Affinity in Iceland', *Nature* **281**, 347 (4 October) emerged incorrectly as a result of a misunderstanding between us and our typesetters on the telephone.
It should read:
Scientific Party, Iceland Research Drilling Project
(J.L. Gibson, editor)

Fluorescence, light scatter, cell sorting

COULTER® have a family of compact reliable instruments that can help you investigate a wide range of cytochemical, histochemical and immunological characteristics. They are the COULTER® Model TPS Cell Sorters.

Select from 5 watt, 2 watt lasers, one or two analysis UV capability and other features to meet your research needs.

Study immunological response, the DNA or protein content of a cell, its surface structure, whether it is alive or dead, how big it is and many other things based on laser-induced fluorescence and/or light scattering.

TPS Systems analyse at rates up to 10,000 cells per second. They also physically sort out cells of interest based on operator-selected parameters at rates up to 4,000 per second.

I am interested in hearing more about the COULTER® TPS cell sorters.

nature

20-27 December 1979

Into the 1980s

CHANGES of Editor at *Nature* are relatively rare: my departure at the end of 1979 will only be the fifth such change in 110 years (admittedly the figures are somewhat distorted by the extraordinary 50 years which the first editor, Sir Norman Lockyer, served). A new editor has yet to be appointed; for the interim Peter Newmark, at present Deputy Editor, will take over. Dr Newmark has had overall responsibility for the selection of biological manuscripts for almost six years and has done this job with distinction. *Nature* will be in excellent hands.

The production of the journal, week by week, year by year, is a collaborative enterprise involving a wide variety of people. It requires the continuing support and encouragement of the board of directors; it requires the endless attention to detail of typesetters, printers and blockmakers; it requires the enthusiasm of advertising, promotion and circulation departments; it requires a lot of hard work from our secretarial and artwork teams. For this I have good cause to be very grateful. And yet my most profound thanks must go to the two groups of people, one small, one large, which between them ensure the continuing vitality of the journal: the editorial staff and a small army of outside helpers.

Tributes to staff can so easily be perfunctory; this one is very heartfelt. My fifteen colleagues who between them decide what goes into the journal, when and how, are a quite outstanding and thoroughly professional team, whose clear appreciation of what *Nature* ought to be and how *Nature* ought to change has been a constant support to me. Maintaining *Nature's* standards calls for a particularly high degree of dedication to work which can at times be exceptionally onerous. The editorial team possesses this dedication in great measure.

And yet all the in-house ability would count for nothing if we could not depend on scientists from all disciplines and all parts of the world for willing help. One of the interesting things about *Nature*, is that this week's reader may be next week's author, adviser, referee or correspondent. The journal belongs more to a community than to a company, an editor or an editorial team. And without the continued encouragement, help and criticism we get from the scientific community, the journal could not survive. We thank you, the scientist, even though occasionally we choose to ignore your advice or refuse to publish your contribution!

ALL manner of scientific and science-political themes rise and fall during an editor's tenure, and perhaps it is foolish to single one out for a last comment. After all reams could be written about the growth of public participation in science-policymaking, the problems of a career structure for scientists, the growing awareness of the vulnerability of the scientist to human rights violations, the place of scientists in development, risks to science funding in a weak economy and so on. Yet if there is one issue which consistently fails to capture headlines yet which ought to interest the scientific community, it is that of arms control and disarmament.

The 1970s has not been a hopeful decade. SALT 2, still not ratified, took an extraordinary time to negotiate and, as far as one can see, does little but confirm existing levels. And in order to sell SALT to the American people, other vigorous armaments programmes are promised. A comprehensive test ban treaty, on which hopes were raised recently, is now unlikely to appear in the near future; if ever it does emerge it is going to be so circumscribed as to be meaningless. The Non-Proliferation Treaty, due for review in 1980, has acquired few new signatories whilst a novel brand of proliferation has emerged, as practised by Israel, South Africa and Pakistan — proliferation by assumption. Multilateral Balanced Force Reduction talks in Vienna are hopelessly bogged down.

There is little progress towards a chemical weapons treaty, whilst there are growing fears of chemical re-armament. Meanwhile arms sales to the developing world continue with the utmost vigour, and nuclear nations improve their arsenals not so much quantitatively but qualitatively. And new weapons, such as laser and particle-beam devices against ballistic missiles get expanded research budgets, regardless of the enormous difficulties there will be in converting ideas into hardware.

Scientists should have a lot to say, and publicly, about the technological arms race. After all in most countries ministries of defence are the nation's largest single employers of scientists and technologists. And yet in recent years the enthusiasm that there once was for asking pointed questions on the assumptions behind military expenditure has largely dissipated — no doubt because of the thankless nature of the task and the seeming impossibility of deflecting inexorable trends.

Will any measures of real self-restraint emerge in SALT 3? Are nuclear weapons bound to spread indefinitely? Is there no way of diverting the resources devoted to military purposes into more constructive channels? These are questions for the 1980s . . . and beyond.

David Davies.

Energy shifts meet environmentalist protests

Moves to convert power stations from oil to coal are generating controversy about the effects on air quality. **David Dickson** reports on one such dispute in New York City.

In a classic trade-off between energy and environmental concerns, New York city last week approved a temporary waiver of its air pollution controls to allow a local power company, Consolidated Edison to burn fuel with a greater sulphur content than is currently permitted.

The company hopes to be able to demonstrate that it is able to use high rather than low sulphur content fuels at its power plants in the city without exceeding federal air pollution standards, and that this will make it possible for the plants to convert from oil to coal, a move supported by President Carter as part of his strategy to reduce dependence on foreign oil.

Local environmental and community groups, however, are protesting against the proposal, which has yet to be given official approval by the federal Environmental Protection Agency. They argue that current controls permitting only the burning of oil with a low sulphur content have been one of the most effective anti-pollution measures in the city's history — and that moving back to higher sulphur content fuels could eliminate some of the gains of the past decade.

Con. Ed. has for several years been trying to get permission to increase the sulphur content of the fuel burnt in its power plants. It claims that not only would conversion to coal be in line with administration policy, but that with escalating oil prices, it would also be financially beneficial to customer companies.

In the previous year, the company's application has been turned down, largely on the grounds that the company has not been able to demonstrate that the current policy results in any particular hardship. Since then, however, the political climate for such decisions has changed dramatically.

In his energy message to Congress in July, for example, President Carter stressed his support for power companies converting from oil to coal. He is expected to submit to Congress soon measures costing even more than the $5 billion that he originally proposed to stimulate the use of coal.

A number of utilities have already benefited from the new climate. In Massachusetts, for example, the New England Power Company, after a four-year battle against stiff local opposition, recently obtained permission to convert three out of four units of a 1,650 megawatt plant from oil to coal, claiming that this would reduce oil consumption in the region by 2.5%.

Last year the company was given permission for an experimental period to burn oil with double the previously permitted 1.1% sulphur content. Company officials admit that pollution levels increased as a result — but point out that they were still within federally-permitted levels.

The current application form Con. Ed. would allow the company to increase the sulphur content of its fuel from 0.3% to 1.5%. It claims that converting three power plants from oil to coal would reduce the nation's dependence on oil by 15 million barrels a year — and would also reduce its customer's bills by 150 million.

"The reason for requesting temporary permission to burn high sulphur content oil is to demonstrate the validity of our contention that such a move will not violate federal primary air quality standards", a spokesman for the company said last week.

Permission for a temporary waiver from current controls has already been given by the New York State Department of Environmental Conservation, and by the New York State Department of Environmental Protection. The application will soon be published for public comment by the EPA, and a final decision is expected by next March or April.

Con. Ed.'s application is being strongly resisted by environmental and community groups in New York. "The City's current requirements that only clean fuels — that is low sulphur content oil and natural gas — can be used has been one of the most successful pollution control strategies that the city has had, and the sulphur content in the air has dropped by 40% since the controls were introduced in 1972", says Marcy Benstock, Director of the New York Clean Air Campaign.

Ms Benstock claims that a comparable reduction in dependence on foreign oil could be achieved through an intensive energy conservation programme. She quotes evidence from a report by researchers at Harvard University that the US could consume 30% to 40% less energy than at present and still enjoy the same standard of living.

Furthermore, she claims, the apparent reduction in costs could be eaten away by additional medical bills and other damage caused by increasing pollutant levels. Even pollution control devices, she argues, will not be able to remove all the additional pollutants caused by converting to coal, such as some of the toxic trace elements.

A new "wrinkle" as one EPA official puts it, recently to have entered the debate, is concern over the extent to which increased sulphur emissions could contribute to a problem receiving growing attention in the US, namely acid rain.

Smog in New York city: will Carter's energy policy make it worse?

According to a spokesman for Con. Ed., the company does not consider this to be too much of a problem since "by and large the sulphur emissions go out to sea". Others, however, argue that not enough is yet known about transportation patterns to judge the potential degree of the problem.

"At present the burden tends to be on society to show that such things are harmful. But the alternative is equally rational, namely that increased emissions should not be allowed until it can be clearly shown that they are not harmful", says Dr Ellis B Cowling, a plant pathologist from North Carolina State University who has studied the acid rain problem, and gave evidence at an earlier hearing on Con. Ed.'s request.

The transport of pollutants is one of the subjects to be examined in a regional study of metropolitan New York and the adjacent areas of New Jersey and Connecticut that has just been announced by the National Commission on Air Quality.

The company's application to use higher sulphur content fuels is being opposed not only by local groups such as the New York statewide Senior Action Council, and People Outraged With Energy Rates (POWER), but also national groups such as the Sierra Club and the Natural Resources Defense Council.

So far, however, their protests have made little impact, and with the current crisis in Iran bolstering programmes for domestic energy prodution, as well as an administration keen to help power companies comply with federal legislation in the least burdensome way — and a relative lack of financial and human resources compared to those seeking the application — their chances of stopping Con. Ed.'s plans seems increasingly slim. □

UN agrees on science and development centre

AFTER three weeks of intense debate, member nations of the United Nations agreed late last week to set up a new policy unit to help carry out the recommendations of the Conference on Science and Technology for Development (UNCSTD) held in Vienna in August.

The new unit will be known as the Centre for Science and Technology for Development. It will be headed by an Assistant Secretary General, and is expected to involve between eight and ten new staff appointments, as well as absorbing some of the resources of the present Office of Science and Technology, which is to be abolished.

The main function of the new centre will be to service the Intergovernmental Committee which, it was agreed at Vienna, should be set up to attempt to coordinate the various programmes within the UN system concerned with applying science and technology to development, and to stimulate further activities in this direction.

A resolution calling for the setting up of the centre was finally agreed in the early hours of last Friday morning by the second committee of the UN general assembly, currently meeting in New York.

In their final form, the institutional arrangements are broadly in line with proposals made by the Group of 77, on behalf of the developing countries, that a strict interpretation of the agreement reached in Vienna implied the creation of a new secretariat.

A number of industrialised countries, and in particular the member countries of the European Economic Community, argued strongly that no new institutional arrangements should be made — and that any new functions could be carried out by existing machinery under the Department of International Economic and Social Affairs.

In the end, however, it proved impossible to devise a compromise formula which all sides could agree upon. And the decision to establish the centre — which will report to, but not be under the direct control of, the Director General for Development and International Economic cooperation, Mr Kenneth Dadzie — was put to the vote.

The result was 97 votes in favour, none against, and 20 abstentions. Countries abstaining include members of the EEC and the countries from the eastern European bloc. Those who voted in favour included not only the developing nation members, but also the Untied States, Canada, and the Scandanavian countries.

The outcome had been held up pending the resolution of a dispute over how much direct influence UN member states should have over the way in which the United Nations Development Programme disburses the "interim fund" which the Vienna conference agreed should be set up prior to the establishment of a long-term science and technology financing system.

The Group of 77 submitted a document arguing that there should be direct involvement of the IGC — which is open to all UN member states — in the administration of the fund. The developed countries, however, and in particular the US which is likely to be a major contributor, made it clear that such a decision would prejudice their agreement to contribute.

The developing countries agreed to back down on their demands, and responsibility for its management will lie in the hands of the administrator and the governing council of the UNDP, although operating within broad policy guidelines laid down by the IGC.

(A pledging conference for the interim fund will be held early next year, and although it seems that the $250 million target agreed in Vienna will not be reached, UN officials are optimistic that voluntary contributions totalling about $100 million can be raised for the two years 1980–1981.)

State Department officials in Washington later expressed satisfaction with the final outcome of the second committee's discussions, claiming that a new centre headed by an assistant director general (some developing countries had argued for an under secretary general) was "just right" — and that to have accepted the Group of 77's proposals for the administration of the interim fund would have destroyed many of the gains made in Vienna.

How the US should pursue the outcome of UNCSTD is likely to be one topic discussed by a new advisory panel on science and technology for development which is being set up under the chairmanship of Mr Tom Pickering, assistant secretary responsible for the Bureau of Oceans, Environment and Scientific Affairs.

The panel is being established under the aegis of the bureau's advisory committee, and its first meeting is likely to be held in public. Additional topics that have been proposed for discussion include energy and development, and a forward look to the global picture in the year 2000.

Meanwhile administration officals are still trying to salvage plans for an Institute for Scientic and Technological Cooperation (ISTC) a centrepiece to US presentations in Vienna, but for which funds have been refused by the Senate.

The House of Representatives has agreed that funds for the institute should be provided. But so far a joint House/Senate conference, which is bogged down on a number of foreign aid issues, has failed to agreeion whether funding for the institute should be provided.

One proposal currently being studied is that the ISTC should not, as initally envisaged by the administration, exist as a separate body within the US aid programme, but remain under the administration of the Agency for International Development, many of whose research programmes the ISTC would be taking over. **David Dickson**

US Congress approves 13% growth in military support for basic science

THE US Congress last week agreed to increase military support for basic research by 13% in the fiscal year 1980, the Senate in particular expressing its support for the Department of Defense's efforts "to overcome years of real decline in funding for this type of research".

The increase, which will bring support of basic research by DOD to about $500 million a year, is less than the 16.7% growth initially requested by President Carter. However, in line with changing social priorities, it is considerably higher than the increases in support for basic science by other federal agencies, for example, the 8% growth for the National Institutes of Health.

Overall, Congress agreed to an 8.5% growth in the Defense Department's spending on "research, development, testing and evaluation", from $12.3 billion to $13.4 billion. Much of this increase will be allocated to support of the "technology base", which includes research on high energy systems, such as lasers and particle beams, as well as high speed integrated circuits.

In particular, support for R,D,T and E activities within the defense agencies — responsible, for example, for the Defense Advanced Research Projects Agency (DARPA) — will grow by 8%.

University research workers are likely to be a beneficiary of the increased spending. Although last year Congress refused to establish a proposed "defense science and engineering programme" aimed at increasing the effectiveness of relationships between the DOD and university scientists, it has given encouragement to the department's efforts in this direction.

The Senate in particular has given support to an increased emphasis on basic research within the R and D budget. Although the House of Representatives had made several cuts in the President's budget request, many of these were restored by the Senate, and subsequently accepted at a conference between the two houses. □

Italy threatens to disrupt three key European research institutions

Italy has drafted a career diplomat to its Ministry of Science expressly to improve its position in European research organisations. **Robert Walgate** reports from Rome.

ITALY was last week preparing to "dissociate" itself from CERN, the European organisation for nuclear research; to block (for a second year) the budget of the European Space Agency; and to refuse to fund JET, the Joint European Torus for fusion research under construction at Culham, England, for a further four-year term.

The three questions were to be raised at meetings of the council of ESA on 18 December, CERN on 19 December, and the Council of Research Ministers of the EEC on 20 December. So Vito Scalia, Italy's Minister for Scientific Research, told *Nature* in an exclusive interview last week.

At CERN, said Scalia, Italy would "consider very seriously" adopting merely an observer status if the appointment of a new director-general were not postponed until April, and if there was not "satisfactory clarifaction of the future programme of CERN".

Italy is undoubtedly the most concerned of all countries at Germany's precise intentions towards CERN, since it emerged that Germany may build a 6-km electron-position accelerator — HERA — at Hamburg. HERA is felt by some to be a competitor for CERN, which hopes to build a similar (but bigger) ring in the 1990s — LEP. Germany denies that LEP and HERA are competitive (see *Nature* 6 December p 546).

But since Germany pays the ceiling of 25% of the CERN budget, and CERN costs and salaries are high, it would arguably be cheaper for Germany to build its own LEP on home territory; hence Italy claims its fears may not be groundless.

Italy's view is also complicated by the fact that of the two principal candidates for the director-generalship of CERN one is the German director of the laboratory where HERA may be built — Professor H. Schopper — and the other is the leading Italian physicist Professor A Zichichi. Schopper's appointment at CERN "would be rather like the entry of a Trojan horse", said one Italian official. "Someone should be appointed whose Europeanism is not in question".

In contrast to this view, however, Professor Schopper has always insisted that his laboratory at Hamburg be considered an international institution. At PETRA, presently its largest accelerator and a world leader, he refused to admit groups composed of one nationality. This at one stage excluded Italy, which wanted to run a massive prestige single nation experiment at PETRA. At present there is no Italian group at PETRA, despite the fact that less than half PETRA's experimenters are German. German-Italian relations are thus somewhat tender on this issue.

At the European Space Agency, Italy will re-affirm its year-old decision to block the ESA budget because, says Scalia, "there is insufficient industrial return to compensate for our £10 million losses over two years on Spacelab". Here Italy believes that ESA's professed policy of distributing contracts among members in proportion to their contributions is manifestly not working. "Germany underwrote Spacelab 54%, Italy 18%", said a ministry spokesman. "But Germany got 62% of the contractors, ourselves 10%".

Scalia also criticised France and Germany for failing to contribute to 'L-sat', ESA's venture in Europe-wide television transmission. France and Germany are bi-laterally developing the equivalent 'TV-sat', leaving Britain, Italy, and five other countries alone in the ESA project.

Italy is also interested in re-organising ESA when the present director Roy Gibson completes his term. "The programme lacks momentum and imagination" said an official. According to Scalia, ESA "should find a strong manager".

In Brussels, Italy would like to link the future of the European nuclear fusion experiment, JET, with that of 'Super Sara' — an experiment on the core 'melt-down' of thermal reactors which would take place at the European Commission's joint research centre at Ispra, north Italy. Britain and other delegations have consistently refused to fund the £35 million experiment, ostensibly because they feel that the costs are too high.

"It would be interesting to know" said Scalia "in what way the countries that oppose such an important programme on reactor safety — one which has been described by America as of great significance — will justify their position to the public . . ."

Germany, an Italian official told *Nature,* had already approached Italy to see if the experiment could be undertaken bi-laterally. Japan has also shown interest. "Whoever can develop a demonstrably safe reactor, will take the world market" said the official. But Italy would prefer that the experiment be undertaken under a pan-European banner.

Criticism of Super Sara has centred on the efficiency of Ispra staff. "We reject that" said the official. Encouraged by the government, Italian unions had sent observers to Ispra, to Brussels, and to Culham where JET is being built, "to assess absenteeism, times of arrival for work and so on". The results put Ispra ahead of Culham, and firmly ahead of Brussels, he said.

"We must have a European programme on nuclear safety" said Scalia. "And at Ispra we have a most important establishment both in the quality of its staff and its equipment." JET and Super Sara, he said, "must either stand or fall together".

Italy appears to be strengthening its stand on European scientific and technological issues. With the change of government four months ago a career diplomat was appointed to the Ministry of Scientific Research as 'chief of cabinet' — the principal advisor to the new minister — and he has been playing an active role in asserting Italy's position in Europe.

The objectives of this exercise may not be entirely a matter of supporting Italy's scientists. The country has taken a strong interest in the industrial aspects of space, having recently announced a £125 million five-year national programme ("fully complementary to ESA's"), and is mindful of the possible applications of the superconducting technology that will be needed in the long term for high energy accelerators. The proof of nuclear safety is related both to sales of reactors and to convincing Italy's public that nuclear power is acceptable.

"Advanced technology" said Scalia "must be a European problem". □

Call for European environment charter

EUROPE'S environment ministers should convene a conference on the environment some time during Italy's forthcoming presidency of the Council of Ministres, Italy announced at a council meeting at Brussels on Monday. The meeting would demonstrate to environmental groups that governments were prepared to tackle environmental problems, said Italy's science minister Vito Scalia last week.

There should also be agreement on a charter announcing the principle of "polluter pays" said the minister, and ultimately, "no pollution".

However, Italy's own record on pollution control is not outstanding. The United Nations Regional Seas Programme, a component of the UN Environmental Programme, recently advised Italy to *lower* its standards for pollution of bathing beaches — because the existing standards were impossibly high. "If Italy applied them, all their beaches would be closed" said a UNEP spokesman. "Better to take a realistic level, and then actually apply it."

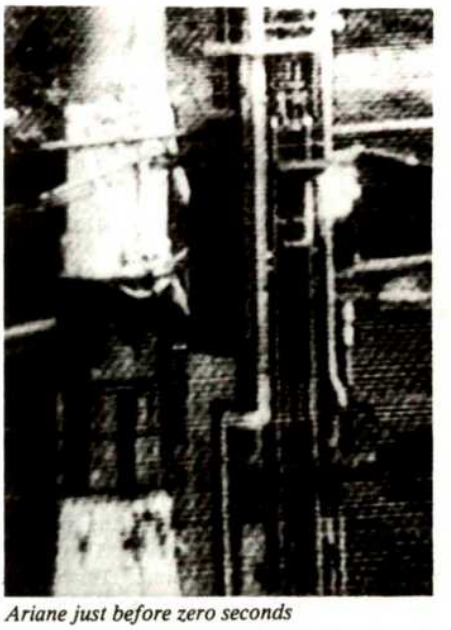
Europe's new space launcher stays on the launch pad

ARIANE, Europe's 200-tonne 3-stage launcher designed to put 1-tonne payloads into geostationary orbit, stayed resolutely on its launch-pad last Saturday during the first attempt to put the vehicle into space. Journalists, watching closed-circuit television screens at the European Space Agency's headquarters in Paris gripped their notebooks excitedly, and radio reporters cleared lines to their news bureaus, as the seconds ticked away to zero. With a few seconds to go, the two "cryogenic arms" which had fuelled the rocket in the previous hours and minutes swung away; there was a cloud of vapur — was it taking off?

No. Ignition was due at zero seconds. Lift-off at +3s. Four seconds, five seconds after zero — was it going to explode, like the first V2s, or like the previous European rocket, Europa, which blew up shortly after take-off? "Mondieu" said the radio man next to me into his telephone. I peered more closely at the screen, thinking he'd spotted something. But then the vapour drifted away, Ariane looked just as before. Anticlimax. ESA officials, long-faced, made for the bar, where the whisky bottles were quickly emptied.



Then the details began to come through. One of the four main engines of the first stage had failed to reach the planned pressure of 9 atmospheres at its combustion chamber — it had reached only 5 atmos — and the computer automatically controlling the last five minutes of launch wisely decided to close the fuel valves. According to some accounts this decision had been made within 0.1s of ignition, accounting for the puff of vapour.

When the disappointment had abated a little, Brian Stockwell, deputy head of the Ariane programme in ESA, said that he'd give 50-50 that it was an instrument rather than an engine failure. "The engines have been fully qualified" he said. Engines early in the development phase had failed to reach design pressure, or had done so more slowly than others, but the problems had been ironed out. The particular engines on this vehicle had never been fired, but they came from a series which was fully proven.

By Monday, detailed records made at the Kourou, French Guiana launch site of the operation of the engines were supporting Stockwell's opinion. An ESA statement said that a malfunction of two pressure sensors on one of the engines "is very clearly shown by the recordings and is attributable to a local overpressure occurring in their feed line shortly after engine ignition, thus putting them out of order. Appropriate steps to avoid a recurrence of such an incident are under study".

Re-launch is planned for next week, the statement says, the time being taken up by re-equipping the vehicle with seals that have been broken and reversing other 'one-way' changes that are made in the last few minutes of the launch sequence. Ariane must also be checked to see if its brief ignition caused any damage.

Officials are therefore hopeful that Ariane will fly with the first and second stages functioning normally. But the third stage, using liquid hydrogen and oxygen, is more doubtful.

Ariane just before zero seconds

While versions of the first and second stages have both been fired successfully in ground tests, the third stage remains to be 'qualified'. In its most successful ground firing, the engines burned only for 90s, instead of the designed 150s. Full qualification is not expected until February, before the launch of a second Ariane; so ESA officials are looking on this first launch as a development flight rather than a test launch. And if of the first four launches planned for the next year, two Arianes successfully put their test packages into orbit, ESA will consider they have a success.

UK genetic engineering regulations relax gradually

THE outcome of the UK Genetic Manipulation Advisory Group's programme to assess the risk from recombinant DNA experiments has been a gradual lowering of the categories of physical containment under which many experiments are now being done, according to Sir William Henderson, chairman of the group. The programme, suggested by Dr Sydney Brenner of the MRC Laboratory of Molecular Biology, Cambridge at the end of 1978 (*Nature* **276**, 104; 1978), identified the type of host vector system as a crucial factor in designing safe experiments.

The development of safe host vector systems over the past year has meant that about 90% of recombinant DNA experiments can now be done under the first two categories of physical containment laid down by the Williams guidelines. Experiments which still come under categories III and IV are mainly those involving the expression of toxins or hormones.

GMAG had been slightly embarrassed, said Sir William when introducing the group's second annual report last week, when the National Institutes of Health in the US proposed 'relaxing' its guidelines about a year ago. At that time, genetic engineering experiments in the UK still came under the more stringent guidelines laid out in the Williams report. Now, however, it was extremely difficult to detect the practical difference between the two systems, said Sir William. The percentage of experiments coming under categories I and II had increased steadily over the past few months from 66% in July to 90% in December.

The procedure of notification of experiments has also changed over the past year. Notification to GMAG and the Health and Safety Executive is now compulsory. Synopses of experiments together with details of the DNA and host vector systems to be used have to be submitted to both bodies and local genetic manipulation safety committees have to recommend the category under which they think the work should be done. Work under categories I and II can begin as soon as GMAG and HSE are notified.

Initial concern that local committees would be incapable of judging categories has not been substantiated. In only one case, said Sir William, did GMAG have to increase the category of containment and on a few occasions it had even recommended lower containment with the used of improved host vector systems.

Despite the success of the past year, however, the members of GMAG still see a need for careful monitoring of recombinant DNA experiments. Most experiments are now done with disabled host vector systems which would not have been developed if GMAG had not existed, said Professor Bob Williamson of St Mary's Hospital Medical School, London and a member of the group. If GMAG ceased to exist now most of the awareness amongst scientists of the need for safety in experiments with recombinant DNA, which it had helped to create, would vanish.

The major problems which GMAG will be tackling over the coming year include industrial scale-up — one case has already arisen — and genetic manipulation in crops.

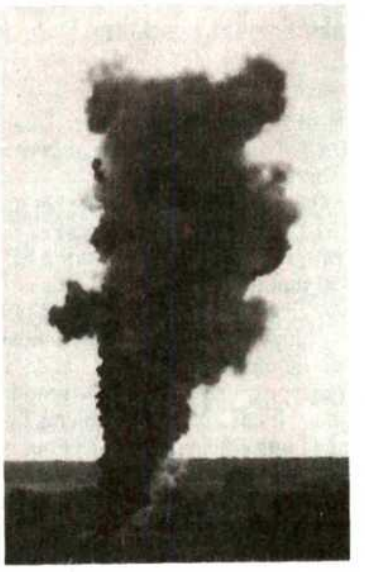
Poland steps up research into mining safety



POLAND celebrated St Barbara's day, (4 December) — the traditional miners' festival — in the shadow of three major disasters that cost the lives of 66 Silesian miners in October. Not surprisingly, the official celebrations stressed the importance of mining safety. Speaking at Katowice, the mining centre of Silesia, party leader Edward Gierek, himself a former miner, called upon "all Polish scientists . . . to develop research into greater safety in mining". At the same meeting the Minister of Mining, Wlodzimierz Lejczak, announced that this year Poland is spending some 15,300 million zloty on mining safety.

Coal accounts for 95% of Poland's energy needs and is a major hard-currency earning export, bringing in some $1,700 million annually; total production now runs at some 200 million tonnes annually. However, Poland's mines are particularly hazardous. Recently, Dr Jerzy Matuszewski of the Central Mining Institute in Katowice told *Nature* that in virtually all Polish mines there is a considerable methane hazard. Moreover underground mechanisation is increasing the dust hazard, and the great depth of the pits — about 1000m — exacerbates the risk of rock-falls.

Dr Matuszewski is director of the institute's own experimental mine — appropriately named "Barbara" — where a network of galleries (5 km in all), provided a test-site for the study of gas explosions.

Researchers also study dust control at the "Barbara" site. The dust control section produces spectacular demonstrations of the almost instantaneous combustion of methane when mechanical cutters are used without the water spraying now obligatory in mines using such cutters. Less spectacular, but equally important, are the routine tests on the combustability of conveyer belts, the monitoring of surface movements, the design of protective clothing, and various anti-silicosis measures.

Mining safety research, in fact, extends far beyong those institutes specifically associated with mining. The Institute of Geophysics of the Polish Academy of Sciences, for example, is currently carrying out a geodynamic survey to attempt to predict earthquakes in mining areas. A special fire-extinguisher recently introduced in hard-coal mines was developed in collaboration with the air-force technical institute. And the Department of Electromagnetic Wave Theory of the Technological Institute of the Academy of Sciences have produced a system of radiocommunication for mines.

Experimental explosion: Poland stresses mining research after major pit disasters

So much for the physical hazards. What about psychological stress? Although there are some psychological experiments going forward — mostly psychomotor studies — little is said officially about the role of physchological stress in mining accidents. And no official statistics of day-to-day accidents are published — although 'unofficial' estimates place the 1978 fatality figure at around 180. One mining official suggested that "production targets" were the greatest single cause of accidents — "but there is little can be done about that!"

Mr Gierek, in his own tribute to the miners' festival, spoke of the new "four-shift" system (three shifts a day, plus one shift entirely off). This was officially introduced two years ago, is being implemented in an increasing number of mines, and is aimed at "improving our miners' working and living conditions". Mr Gierek failed to mention that all three of the mines involved in the October disasters had "four-shift" schedules.

Computers can replace maths for scientists, says Soviet professor

COMPUTERS must inevitably change the whole structure of mathematical training, from scientists down to schoolchildren, according to Professor Aleksandr Kitaigorodskii. Writing in the prestigious Soviet weekly, *Literaturnaya Gazeta* (No. 43, 1979), he envisages a future with a small computer on every classroom desk, where pure mathematics will become a form of art and "culture", and problem solving will have virtually vanished from the academic syllabus. With the advent of the computer as "co-respondent", says Kitaigorodskii, the long "marriage" of mathematics and science is ripe for "divorce".

His article is clearly intended as something more than idle futurology. A well presented "press campaign" is a standard Soviet gambit for informally airing a proposed major policy change. A few issues later, (no. 49), an article by Professor M Evgrafov of the Mathematical Institute of the Academy of Sciences of the USSR ostensibly presented a counter-argument. This, however, while counselling caution in planning reforms, only served to reinforce the theme of mathematical irrelevance. Evgrafov claimed in particular that "not a single result obtained in pure mathematics" has had any practical applications for at least 50 years, while by that time "90%" of all such results have now been completely forgotten; and even at the time of its discovery, the "most elegant mathematical result" will be understood by "not more than 100 persons". Since, moreover, so few people are capable of "creative mathematical work", he finds the current insistence on mathematical training in higher education and research instutites, "wanton", "rigid", and "useless".

As for problem-solving, he suggests that in the future this will become pre-eminently the domain of the programmer ("a person of middle-level qualifications") and only if the problem has been wrongly formulated will it be necessary to revert to the "tried

An apple for the programmer

and tested" method of the "Old Testament" — calling in a highly qualified mathematician.

More vehement counter-agruments have been reduced so far to small type at the foot of a column. They deal mainly with a computer's inability to "solve" anything, or, more specifically, to deal with continuous or infinitesimal processes.

A somewhat more original suggestion is advanced by A Badaev, a Candidate of Technical Sciences (roughly equivalent to a PhD) from Penza. Without the common language of mathematics, he says, science would soon be reduced to a state resembling "the well known Biblical legend of the Tower of Babel".

Native peoples oppose uranium mining

Representatives of native peoples met in Denmark recently to discuss the problem of uranium mines on their lands. **Roger Moody** reports

John F. Racmussen.

The Narssarsauq seaboard: Greenland has vetoed further development of uranium

THE First International Conference on Uranium Mining in the Third and Fourth Worlds was remarkable, not only in its attendance of 500 anti-nuclear activists and representatives from the developing world, but in the fact that it occurred at all. Held in Copenhagen on 25–27 October, the conference was organised at short notice by three Danish anti-nuclear groups.

Taking advantage of the fact that two US Indian delegates, Winona LaDuke and Herb Blatchford were visiting Europe (see *Nature*, 11 October 1979), the Danish anti-nuclear group 'OOA' issued invitations to activists and representatives of native peoples from Africa, Australia and Greenland.

Just three weeks before the conference, the ruling Siumut party in Greenland had strongly condemned the involvement of their economy in the nuclear age precipitated by an energy-hungry EEC. In particular Siumut vetoed further immediate development of the Narssarsuaq uranium deposit (27,000 tonnes) on the far south-western tip of Greenland. And by coincidence, two Australian Aborigines also happened to be visiting Europe at the time of the conference. They were trying to set up an Aboriginal information centre one of whose aims would be to work for a moratorium on the development of the Ranger, Nabarlek and Jabiluka deposits, all on Aboriginal land in the deep Australian north.

Mick Miller of the North Queensland Land Council, the largest single body representing any of Australia's original people, talked about the struggle for land rights, pointing out that Aborigines had been aware of the potentially devastating nature of uranium "thousands of years ago". Using the powerful images of Aborigine culture, Miller told of an Aborigine belief about the land on which the Ranger mine is due to go on stream around 1981. The story has been told through generations that if the earth is disturbed on this spot, *gabo djang* (green ants) will rise through the crust and destroy the world.

Herb Blatchford's forebears had also sensed the enormous importance of the 'Four Corners' area into which they moved and settled 4000 years ago (the Four Corners comprises New Mexico, Colarado, Utah and Arizona). However, when uranium mining started in New Mexico (initially for US nuclear weapons) about 30 years ago none of the Navajo or Pueblo people in the Four Corners was told the full extent of what was going on: "We asked — why do we feel the nausea, see our hair fall out, why do our teeth weaken, why do we get up in the morning and have no breath? We went to books, looked back at history. Then we went to the Japanese. We went to Enuwetok atoll and asked them. Then we went to the Nevada Platte people. They all gave us the same answer: *Radiation*."

Greenland's delegates seemed unaware of the full implications of allowing uranium mining on their land. Robert Petersen (surely the only Inuit eskimologist in the country) received polite applause when he reflected the Siumut position that mining should only proceed "if all the dangers of radioactive pollution and waste dumping are solved". Of one thing, Petersen was quite certain: "The mine cannot be a solution to the increasing unemployment among our people. If Narssarsuaq goes ahead, it will produce only a few jobs for our people, and bring in even more outsiders."

Another Greenlander took issue with Petersen on this, and became the only delegate to approve of mining "provided the safety problems are solved" since "we must have an economic base on which Home Rule can work". Jorgen Hertling is a member of the Atassut party which has strong links with Denmark, Greenland's former colonial rulers.

The two high spots of the conference were both unexpected. Immediately after Hertling left the platform — to stony silence — two young Greenlanders rose to announce (in both Inuit and English) that they had just decided to form an anti-uranium mining group in their country. During the next few months, they will travel round the scattered seaboard communities mobilising against the Narssarsauq project, and strengthening the veto already imposed on it. (There is a widespread fear among Greenlanders that the Danish government will override the veto, under pressure from the EEC.)

But most surprising was the address given by the only 'Third World' delegate, Hadino Hishongwa from Namibia. Hishongwa is the South West Africa Peoples' Organisation (SWAPO) representative in the Nordic countries, Austria and West Germany. Although opposition to foreign control of Rössing, the world's largest operating uranium mine (1978 production: 5000 tonnes uranium oxide), received majority support in the UN Assembly four years ago, SWAPO has never argued against uranium mining as such until now.

"Uranium is an evil", announced Hishongwa. "It is a threat to Namibia and a threat to the entire world. SWAPO doesn't want to exploit it, even when we are independent."

As well as the Rössing mine (in which Britain's Rio Tinto Zinc Corporation has a 46.5% beneficial interest), South Africa's huge General Mining Corporation and France's Aquitaine are involved in prospecting further uranium lodes in the Swakopmund area, and Namibia's actual deposits could rival those in Gabon and Niger.

So ended a conference which was rather short on facts, somewhat higher on energy and certainly bounding with rhetoric. Whether native or 'natural' peoples in the developing world live on 80% (as was claimed by the conference organisers, OOA) or 40% (my own estimate) of the West's reasonably assured uranium reserves, they are certainly the most vulnerable groups. And if uranium exploration and mining expands by up to 150% — as this year's Uranium Institute's annual symposium proposed it should — future conferences should see greater representation from native peoples who did not hear about, or could not get to, the Copenhagen gathering. □

news in brief

Dioxin traces found in soldiers exposed to defoliant: Research workers at the Veteran's Administration in Washington announced last week that tests had revealed the presence of small amounts of dioxin in fat tissues taken from men who were exposed to the defoliant 2,4,5-T during the Vietnam war. Dr Lyndon E Lee told a public meeting of the VA's Advisory Committee on Health-related Effects of Herbicides that analysis had revealed traces of dioxin ranging from three to 57 parts per trillion in fat tissue taken from 33 individuals, including a control group of 10 who had not served in Vietnam. However he added that the amounts of dioxin, a highly toxic contaminant, were so small that it was impossible to attach any significance to them.

Meanwhile President Carter has announced the setting up of an interagency working group to study the long-term health effects of exposure to Agent Orange and other herbicides which were used extensively during the Vietnam war, and which many veterans are now claiming responsible for complaints ranging from liver disorders to chromosomal damage. According to the White House the working group will have the major responsibility for making public the results and implications of research on the health effects of phenoxy herbicides and their contaminants.

London School of Hygiene and Tropical Medicine fears closure: London University's School of Hygiene and Tropical Medicine may close if the government's proposed increase in fees to foreign students goes ahead. The school now charges overseas students £1200 per year which would have to increase to £5000 next year and to £7000 by 1982-1983 if the government goes ahead with its plan. Of the school's 249 full time students and 1023 part time students 58% are from overseas from a total of 85 countries. The school is a postgraduate institution offering MPhil, MSc and PhD degrees and is knwon for research and teaching in tropical diseases as well as community medicine, occupational medicine and epidemiology and statistics. Gordon Smith, dean of the school, said that the probable loss of overseas students was not just a question of money. "Our students are a resource of considerable magnitude. They are experienced and knowledgable and the school's research programmes could not function without them." Smith also stressed that since the Soviet Union was the only other country offering research and training in tropical medicine at a "reasonable fee" that a policy directed against overseas students might have "undesirable foreign policy implications".

Other internationally known schools of London University threatened by closure because of the proposed increases include the School of Oriental and African Studies with 35% overseas students and the London School of Economics with 37% overseas students.

ASTMS calls for MRC tenure reforms: The Association of Scientific, Technical and Managerial Staffs is discussing proposals for extensive reforms in the UK Medical Research Council's tenure procedures. A working paper circulating to ASTMS/MRC national advisory committee affirms ASTMS general policy that "potential dismissal, including the end of fixed term contracts, should be the subject of negotiation and not be solely at the employer's discretion". The proposals call for changes in both new appointments and tenure procedures. Present non-renewable three year appointments would be replaced by three year fellowships with a one year renewable option, a retirement contribution, no age limit, no waiver clause and would end with a "substantial cash gratuity if the fellow is not taken on to permanent staff". The proposed tenure procedures for scientific staff would replace the present five year scheme with a one year probationary period followed by a tenure decision. The tenure decision would be made with the candidate having full access to submitted reports and in the case of denial reasons would have to be given.

UK National Physical Laboratory Chemical Division to close: A 4% cut in the budget of the National Physical Laboratory is to be applied solely to the division of Chemical Standards. Chemists in the division were told that a decision had been "made centrally" to close two sections in the division because "the jam had become too thin to spread further". The two sections, Reference Materials and Thermodynamic and Phase Equilibria Data, employ two thirds of the Division's 60 scientists and the entire division will close as a result. The scientific staff has been given two years and three months to find other jobs. It is not clear whether the NPL will employ them since the Chemical Standards Division is the only one devoted to chemistry at the NPL.

UK energy report calls for development of fast breeders: A major Department of Energy report on energy technologies for the UK regards the fast breeder reactor as the only economic solution to Britain's electricity needs over the next fifty years. On the basis of the assumptions made in the report it is estimated that it will ultimately be economic to install nuclear power to generate between 80% and 90% of public electricity supply. The fast breeder is seen to be the likely solution for the ensuing world-wide competition for uranium. The report says "Only by introducing the fast reactor on a large scale by the early decades of the next century can the world demand for uranium be brought within credible bounds". Fusion power is seen to be unrealistic and alternative sources of energy are regarded only as insurance against shortages. *Energy Technology for the UK* Vol 1 (£3.00) Vol 2 (£5.75). HMSO.

UK to provide free science consultancies for industry: A scheme to facilitate "industrial exploitation of innovations originating in research" has been approved by the Science Research Council and the Royal Society. The two bodies will provide £100,000 a year for ten fellowships to enable academic scientists to "work directly in the productive process" and for industrial scientists to learn new basic research techniques. The scheme is expected to be effective in "growth technology areas" in which there is "quite a distinct demand on the industrial side". Although the scheme is intended to be "flexible" genetic manipulation techniques are expected to be in high demand in industry circles.

BSSRS calls for new safety procedures for hospital radiation hazards: The British Society for Social Responsibility in Science Hospital Hazards Group has issued a report calling for new radiation limits and redundancy agreements for hospital workers exposed to radiation. The report suggests that trade unions should negotiate local limits at each hospital that are substantially lower than established upper limits since "all research indicates that the majority of exposure can easily be kept at 1/10 of the current limits".

The report also calls for trade unions to negotiate lay-off agreements whereby workers who receive their maximum allowable yearly dose of 5 rem are transferred to new jobs without loss of pay or seniority. In addition the report recommends that protective safety clothing be a measure of "last resort". Substitution (e.g. ultra sound for x-rays) and containment or shielding are seen to be superior safety measures. *Radiation Hazards in Hospitals.* British Society for Social Responsibility in Science, 9 Poland St, London W1. 18p.

Correction: In the correspondence "Fast reactors will be problematical and expensive" (22 November, page 358) there was an error in the fourth sentence of the second column. It should have read '. . . spokesmen for the Nuclear Installations Inspectorate stated "we have indicated the seriousness with which the NII views the possibility of whole-core accidents in fast reactors. The consequences are potentially worse than for major accidents in a thermal reactor system . . .".

Recombinant DNA: have recent experiments assessed all the risks?

Experiments to test the safety of cloning viral genomes in *E. coli*, published earlier this year, have allayed fears about the risks of recombinant DNA. But, argue **Barbara Rosenberg** and **Lee Simon**, the experiments actually indicated some worrying aspects of the behaviour of recombinant DNA.

TWO reports on the assessment of risk from recombinant DNA were published in March, 1979 in *Science* (**203**, 883; and 887). These experiments were designed "to evaluate certain postulated machanisms of possible biohazard stemming from recombinant DNA research with *E. coli*". The authors "view these results as being highly reassuring with respect to the safety of cloning viral genomes in *E. coli*". This statement, in our opinion, reaches far beyond the results presented. The new data actually confirm several aspects of hazard mechanisms that have been postulated, but they do not address other aspects that must be investigated before the overall hazard can be evaluated. Nevertheless, the published conclusion has been widely accepted and the reports have been cited as cause for the relaxation of fears about risk to the public of gene-splicing experiments (for example *The New York Times* 2 May; *Nature* 15 February, page 505).

A team headed by Wallace Rowe and Malcolm Martin of the National Institute of Allergy and Infectious Diseases did the research at Fort Detrick. Their experiments tested the ability of certain recombinant molecules containing polyoma virus DNA to cause viral infection in mice (polyoma virus grows readily in mice and is easily detected). Subsequently, a more cautious report of very similar experiments, sponsored by the European Molecular Biology Organisation (EMBO) appeared in *Nature* (28 June, page 811). The EMBO group prepared the same types of recombinants and tested for virus production in cultured mouse cells; they plan to test later for infectivity in animals. The assay used in both studies detected infectious virus particles produced by the recombinant molecules, and so required total functioning of the recombinant polyoma virus DNA to produce a positive result.

Only a relatively uncommon type of recombinant molecule was found to produce infectious particles. (This contained a tandem polyoma insert, which because of its head-to-tail double structure is capable of regenerating free circular polyoma DNA within the cell.) Ordinary recombinant molecules with a single polyoma insert did not do so. This is indeed expected in the light of current molecular biological knowledge. To produce infectious virus from a single polyoma insert would require specific mechanisms for excision or replication which are not known to exist.

Furthermore the particular recombinants chosen for study are incapable of the full genetic function necessary for virus production. They were all constructed with enzymes that cleave polyoma DNA within a transcriptional region and in the resulting recombinants a part of the genetic information is disjoined from its control region and could only be reconstructed by regenerating free circular polyoma DNA. The production of free virus particles by recombinants with a single polyoma insert would thus require a highly unlikely intracellular event. The observed lack of infectivity conveys a false sense of security which arises from the method chosen to evaluate the possible biohazard.

In fact the production of complete, infectious DNA viruses by recombinant DNA, as tested in these experiments is one of the least probable hazards of recombinant DNA technology. There are other dangers in cloning viral DNA that are at least as serious, and far more probable: in particular the possibility that one or more viral genes could function without the production of a complete virus. In the case of tumour viruses such as polyoma, partial genetic functioning of the virus DNA is considerably more dangerous than the production of infectious virus. The action of a single viral gene can transform a cell towards malignancy and consequent tumour formation, whereas complete virus function leading to a productive infection is harmless to mice.

The functioning of single genes from other sources, for example toxin-producing genes, could also be hazardous. This is the kind of risk posed, in general, by the cloning of eukaryotic DNA (DNA from organisms other than bacteria). Single gene function is a 'worst case' hypothesis — it suffices, for example, for a scenario which envisages the spread of microbial-borne cancer. A test for single gene function in recombinant molecules therefore provides a much better basis than infectivity for conclusions on the safety of the technology.

The team led by Rowe and Martin have now published information on this subject (*Science* **205**, 1140; 1979). Their results show that polyoma virus DNA in recombinant molecules induce tumours in newborn hamsters with a frequency similar to that of non-recombined polyoma DNA; the recombinant molecules can therefore function genetically in mammalian cells. These positive results indicate that recombinant DNA can be highly hazardous if it is brought into appropriate contact with an animal.

In these tumour induction experiments, 19% of animals injected with intact, uncleaved polyoma DNA developed tumours, and 19% of animals injected with intact tandem-insert polyoma DNA also developed tumours; intact recombinant λ or plasmid DNAs with single polyoma inserts gave variously 0.6 and 9% tumorigenicity (Israel *et al. Science* **205**, 1140; 1979: Table 2). The overall variation in the tumorigenicity of intact recombinant molecules, 0-19%, is a result of the small numbers of animals seen; similar variability was seen in similar conditions for tumorigenesis by free intact polyoma DNA (*J. Virol.* **29**, 990; 1979; Table 5).

An accurate, quantitative determination of tumorigenicity is not possible from the data given, but it is clear that for both single and tandem-insert recombinants the tumorigenicity is of the same order of magnitude as that of free polyoma DNA. One can conclude that the insertion of polyoma viral DNA into a vector molecule from a different source does not significantly change its tumorigenicity and is, therefore, not a safeguard. Moreover, recombinant DNA can clearly enter hamster cells and the region of the inserted DNA required for tumour induction evidently finds genetic expression. This indicates the potential genetic activity of recombinant molecules containing DNA from any source, not just viruses.

The successful infection experiments with recombinants containing tandem polyoma inserts also indicate that recombinant DNA can enter mouse cells. The authors point out that the recombinant DNA is not recognised there as foreign and that the polyoma DNA retains its biological activity after cloning in bacteria. These experiments also reveal a new element in the hazard that may be posed by genetically active recombinant molecules. The recombinant molecules became 100-1000 times more infective when they were enclosed in λ-phage particles (*Science* **203**, 887; Tables 2 and 3), although it is not emphasised in the text. The phage coat apparently protects the DNA from degradation and facilitates its entry into mouse cells. Thus, polyoma-λ recombinants, both single and tandem are endowed with a large advantage over free polyoma DNA. A close comparison of the polyoma dosages in free DNA and λ-phage particles in the tumour-induction experiments (*Science* **205**, 1140; Table 2)

Barbara Hatch Rosenberg is at the Sloan-Kettering Institute for Cancer Research and Lee Simon is at the Waksman Institute of Microbiology, Rutgers, New Jersey.

© 1979 Macmillan Journals Ltd

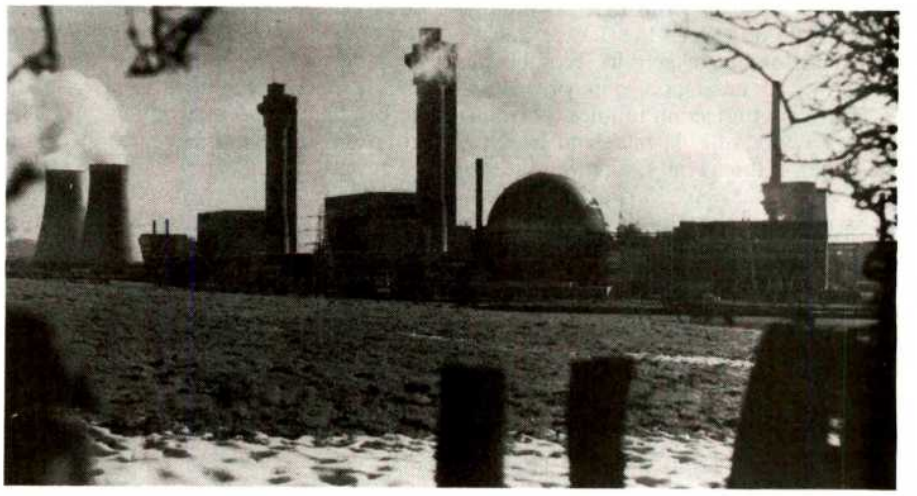
confirms this advantage. Thus, if *Escherichia coli* containing polyoma-λ recombinants should come into contact with appropriate animal cells, λ particles possessing recombinant DNA molecules could readily enter the cells and act genetically to induce tumours.

The key question now is whether *E. coli* (or other hosts) containing recombinant DNA can provide a new route by which viral or other genes could find their way to sensitive species.

This question is not addressed in those risk-assessment experiments undertaken so far, although it must be answered before we can be reassured as to the safety of cloning recombinant viral DNA in *E. coli*. Although one of the papers from Rowe and Martin's laboratory states that *E. coli* containing polyoma-recombinants were not infective when injected into mice, this is misleading because they tested too small a dose of the recombinant contained in *E. coli*. In the case of free recombinant DNA a larger dose is required (their Table 2 and 3). (The same is true in the tumour-induction experiments.)

E. coli containing polyoma recombinant DNA induced no tumours (*Science* **205**, 1140; 1979; Table 1) but for technical reasons the polyoma dose contained there in was an order of magnitude lower than the minimum dose required for measurable results with the number of animals used, as shown by the DNA data (Table 2). Moreover the authors point out that experiments involving injection of live *E. coli* may tend to be biased in favour of negative results.

Since most of the animal data were obtained by injection, the relative infectivities or tumorigenicities obtained in this way reflect the ability of the DNA molecules (either free or in phage particles or bacteria), to enter and act in mouse cells with which they have artificially been placed in contact. But injection is not a normal mode of accidental exposure of an animal to bacteria.



There are many normal ways in which *E. coli* can accidentally enter mammals and proliferate at various sites; urinary tract infection or gut colonisation are typical examples. If an *E. coli* strain containing a recombinant were able to colonise an animal in these or other ways, or transfer the recombinant to another bacterium that could do so, the amount of the recombinant could eventually be greatly amplified internally. The animal would then be exposed to the recombinant continuously over a long period of time, thereby increasing the risk substantially, even if the event is of low probability when infection by polyoma virus itself is considered. Via the recombinant, polyoma genes would be given a new route of access to the animal.

E. coli host-vector systems have been developed with the aim of minimising this possibility, but their reliability has not yet been demonstrated. Indeed, risk-assessment experiments in progress under contract to the US National Institutes of Health indicate that survival of EK2 strains in the human gut (other sites have not been systematically tested) and in the environment is considerably greater than originally anticipated, and plasmid vectors can increase survival. The likelihood that recombinant EK2 strains may be able to transfer genetic information to indigenous microorganisms in various natural environments may therefore be significant, but this has not yet been adequately tested.

The extent of the hazard posed by a potentially functional recombinant clearly depends on whether the host-vector system used can provide a new route to the animal, or plant, or to man. The main import of the present risk-assesment experiments which in effect rule out any automatic safeguards at the levels of cellular entry and gene function, is to give new importance to the question of new routes of genetic access that could be provided by *E. coli* or other cloning hosts. Until this has been fully studied, there is no basis for reassurance on the risks of recombinant DNA. □

Nuclear power: the threat to personal freedom

Robin Grove White looks at the implications for civil liberties in the UK of a major increase in nuclear power.

The UK government's proposal to expand the nation's nuclear capacity will increase debate on the long term impact of nuclear power on civil liberties. This issue has already become central to the debate in other European countries.

The Royal Commission on Environmental Pollution first raised the issue of nuclear power and civil liberties in its sixth report (Cmnd 6618) in 1976. Together with subsequent independent studies, the report argued that a major commitment to nuclear power, and in particular to the plutonium fuel cycle, would require extensive security measures to safeguard nuclear materials such as plutonium from theft and sabotage. These safeguards would damage relations between the individual and the state.

Extensive vetting of workers inside and outside the electricity industry, the growth of unconventional armed protection for nuclear facilities and materials, wide-ranging surveillance of dissident groups and constraints on the flow of information about nuclear power to the news media would all contribute to increasing authoritarianism.

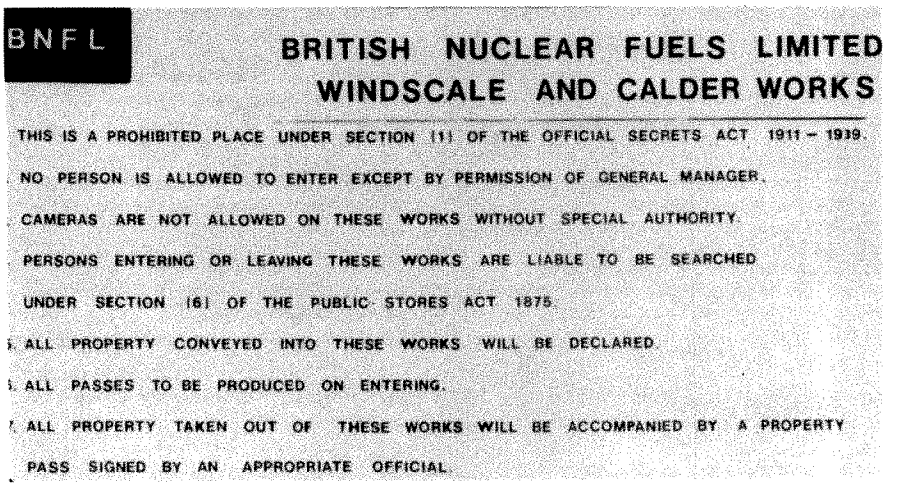
The government and the nuclear industry were not impressed with these arguments. In June 1977, the Department of Energy said that future nuclear plant could be designed to eliminate many of the potential civil liberties' hazards. Industry spokesmen such as Sir John Hill Chairman of the Atomic Energy Authority (UKAEA) went further: a combination of technical fixes such as radioactive 'spiking' of fuel elements, siting fuel fabrication plants and power stations in the same place and physical obstacles at vulnerable points in the fuel cycle would obviate the need to intrude on civil liberties. In any event, it was maintained, thieves were unlikely to be interested in materials such as plutonium.

Such confidence is increasingly hard to endorse. No such technical fix has been found to be politically or economically feasible and there have been ominous developments.

On 26 October 1979, the first International Convention on the Physical Protection of Nuclear Materials (for peaceful purposes) was concluded in

Robin Grove-White works for the Council for the Protection of Rural England.

0028-0836/79/510774-02$01.00



© 1979 Macmillan Journals Ltd

Vienna. The convention established draconian measures to protect the use, transport and storage of civil nuclear materials, including the exchange of information between national security authorities, rigorous vetting of individuals with access to sensitive points in the fuel cycle, arming of guards and an agreement that all exchanges of information concerning nuclear security should be confidential. The convention is far franker in its recognition of the hazards of civil nuclear power than the UK.

The security community has recently said that surveillance, vetting and secrecy will play a growing role in economies opting for nuclear power. The 1978 Rand Corporation Report, *Attributes of Potential Criminal Adversaries of US Nuclear Programs*, stressed the limitations of physical security in guarding against theft or sabotage of civil nuclear materials. Rand lays emphasis instead on the need for more stringent security clearance procedures, for secret armed police and for a pervasive air of 'uncertainty' (i.e. secrecy) to thwart nuclear hijacks.

This agrees with a senior police official who recently said at a high-level UK seminar, that, for nuclear materials, investment in intelligence tends to be more cost-effective than an equivalent investment in physical containment.

An indicator of the growing gap between the UK's earlier official reassurance and

hard reality is the growth since 1976 of the UKAEA's Special Constabulary. This private armed police force operates on a constitutionally unique basis, its actions shrouded from public (and parliamentary) view for security reasons. Justice, an all-party association of UK lawyers, has commented that the constabulary's structure "conflicts with all our traditions of civilian and politically accountable policing".

In February 1977, Friends of the Earth and others asked the then Energy Secretary, Tony Benn, to comment on the likely scale of the constabulary's expansion to meet the security demands of a hypothetical 127GW nuclear programme. His department's considered reply was that "not more than a few hundred" extra armed constables would be required to guard even this massive programme. However, between 1976 and 1979, the constabulary's strength increased 50%, from 400 to 600 — and at a time when there have been no additions to the civil nuclear programme.

There have also been developments in the levels of vetting now thought appropriate for staff of relatively low skill in the nuclear fuel industry. There has always been extensive vetting of the personal associations and political affiliations of employees of the UKAEA and British Nuclear Fuels Ltd. The extent of such security screening has now become a significant irritant in union-management relations. At a conference on Trade Unions and Nuclear Power in November 1978, a senior official of the Electrical, Electronic, Telecommunications and Plumbing Union (himself no critic of nuclear expansion) expressed dismay at the escalation of security vetting at Windscale.

Recent foreign experience suggests that intensified surveillance of bodies opposed to nuclear power is a likely concomitant of nuclear expansion. Reports from West Germany, Australia and the United States point to cases of spying and infiltration of campaigning groups. Over the past few months in the UK, commentators as various as the *Daily Telegraph*, Sir Fred Hoyle and the Institute for the Study of Conflict have pointed to the potential advantages to the Eastern Bloc of a strong UK anti-nuclear movement. It is likely that such views are already reflected in UK security, given the problems that could arise from disruption of the nation's energy supply and the dangers of nuclear materials in the wrong hands.

But how far will such surveillance extend? And how is it to be kept within bounds? Two rival imperatives clash. Public understanding of the full implications of nuclear power demands openness about civil liberties' before irrevocable decisions are taken. But the imperative of security (itself the very source of the difficulty) dictates silence.

Weighing evidence about this conflict in his 1978 report on the Windscale inquiry, Mr Justice Parker could offer "no solution at all". He opted for security and silence.

In June 1977, the Energy Secretary, Tony Benn, stressed that "the government are well aware of the need for discussion of such an important issue to take place on an informed basis . . . [They] will make every effort to ensure that adequate information is available. They are confident that it will be possible for Parliament to perform its traditional function in this area". Yet just six months later, in reply to a Commons question about the range of security measures needed for fast breeder reactors, Mr Benn was brutally laconic: "I can only give the classic answer: that I am advised that the increase in surveillance and vetting will not go above a normal level".

Powerful arguments for greater openness have been made. In a recent article in *International Relations*, Cambridge historian Christopher Andrew urges: "As the dreadful day of the terrorist with a nuclear device in his suitcase draws gradually and inevitably closer, intelligence surveillance of potential terrorist groups will have to be increased. And it is essential that increased surveillance should have the support of informed public opinion . . . The only alternative to a public informed about the intelligence services is a public misinformed about and suspicious of them".

But is such openness credible, or even desirable? Each additional nuclear commitment compounds the tensions over civil liberties as it leads towards ultimate reliance on the plutonium-fueled fast breeder reactor. In this way, argue the civil libertarians, new thermal nuclear power stations are contributing towards new and unhappier relations between the individual and the state. In April 1977, for example, the International Commission of Jurists, a group of leading lawyers concerned with human rights and the law, met in Vienna and expressed "grave concern about the dangers to human rights created by nuclear weapons and materials and nuclear power programmes". It called on all governments to "take these dangers into account before forming a policy on nuclear power".

Tony Benn was undoubtedly worried about these issues when he was Energy Secretary, as some of his public statements testify. But there is little in the public record to suggest that civil liberties have weighed significantly in the decisions of David Howell, his successor.

It is conceivable that the pursuit of nuclear power will damage civil liberties less than would the pursuit of an alternative long term energy strategy, such as the low energy growth programme outlined earlier this year by the International Institute for Environment and Development. But the government has certainly not demonstrated this.

The most important social dimension of nuclear technology may be going by default in Whitehall. □

Stench on the New Jersey Turnpike

SIR, — The central point in Thomas Jukes' recent review of *Malignant Neglect* (8 November, page 166) — that the book treats facts cavalierly — is amply documented by the quotations he cites. I should like to point out, however, that Professor Jukes' own attitude to facts is not beyond criticism.

Jukes quotes the book's description of the "stench" and emissions from the large petrochemical complex near the New Jersey Turnpike, which (it implies) is related to 14,000 cancer deaths in New Jersey. He then dismisses the statements on the grounds that he once drove the same route at 6.45 pm and observed neither stench nor emissions, apart from steam.

Having myself travelled this route, by car or train, at least 50 times over the past 20 years, I can assure Professor Jukes that the petrochemical stink in the area is no man's invention. Since I did not keep score, I cannot swear to how often I experienced it — but it was often enough for the experience to become an absolutely expectable feature of the trip.

Jukes' own account provides a clear explanation of why he smelt nothing — assuming, of course, that the complex was in operation at 6.45 pm. "To the west," he notes, "there was a brilliantly clear sunset in which a range of hills, 30 miles away, was sharply etched against the sky." That degree of visibility could exist only amid a continental polar air mass entering the area — which is normally associated with northwesterly winds. The complex lies southeast of the highway.

New Jersey does in fact have one of the highest cancer rates in the US. Whether this has any connection with emissions from the chemical manufacturing facilities with which northern New Jersey is sown has yet to be established. However, a number of reputable authorities, including the US Public Health Service, consider the possibility real enough to be worth investigating.

Yours faithfully,

ROBERT CLAIBORNE

New York, US

Research ceased during the Cultural Revolution

SIR, — Having recently returned from working at the Institute of Vertebrate Palaeontology and Palaeoanthropology in Peking I would like to challenge Tilman Spengler's assertion (15 November, page224) that this was one of the institutes of the Chinese Academy of Sciences that "worked very well" during the Cultural Revolution. Certainly the institute was not physically closed down, but a research institute where no research is permitted, can hardly be said to be working well. By 1972 research activity was starting up again, but for six years nothing was heard of vertebrate palaeontologists or their work. The Chinese vertebrate palaeontology journal *Vertebrata Palasiatica* ceased publication in 1966 and did not reappear until 1973. The impression gained from my Chinese colleagues was that the Cultural Revolution was a period of enforced isolation and stagnation.

Finally, I would like to comment upon the statement attributed to the three Chinese scientists visiting Britain: 'In China we tend to work more collectively. It is unheard of for an individual to work alone . . .'. I suspect this comment may well have arisen from a semantic misunderstanding. Certainly from my observations, Chinese scientists in my own field, at least, work exactly as they do in Britain. The individual scientist is employed with others in an institute, will collect raw data jointly with colleagues, will discuss his or her results with colleagues, may cooperate with others to produce joint papers, but in the main does scientific research alone. This much is evident from even a cursory glance at the authorship of Chinese scientific publications.

Yours faithfully,

L.B. HALSTEAD

University of Reading, UK

China has many aspects

SIR, — In your introduction to the two reports on "China: the legacy of the Cultural Revolution" (15 November, page 224), you used the phrase "views of China are as diverse as its visitors", and seemed to imply a disagreement between myself and Tilman Spengler. I would like to point out, however, that the diversity is a reflection of the "diverse aspects of the problem", and not necessarily a "diversity of opinions". Spengler discussed policies, which had their positive sides; I was talking about the excution of some of the policies, which led to intense suffering by some people.

My report was written shortly after my return when the depressing discoveries of the suffering by my friends and relatives were still fresh in my memory. If I had been more emotional than I need to be, my motives could be understood, if not forgiven.

Finally, I inadvertently used the expression "tradition-bound arrogance" when I really meant to say "tradition-bound smugness". I am sorry for the unfortunate choice of a word that has been offensive, when no offence was intended.

Yours faithfully,

KEN HSÜ

ETH, Zürich, Switzerland

New select committee seeks expertise

SIR, — The Education, Science and Arts Committee held their first meeting on Thursday, 29 November.

In recommending the setting up of the new select committees, the Procedure Committee stated, "We hope that, as the new committees become established . . . they will develop methods of work which will enable them to respond more speedily to current problems and to new policy proposals". In view of this we have decided to study a number of subjects and report fairly rapidly during the coming year. By fairly rapidly we mean we are trying to set ourselves a maximum time of two months between starting to take evidence and reporting. We have facilities to hire specialist assistance. We have not yet decided which shall be our first subjects of study but we expect them to be in the field of education.

The Committee are anxious to ascertain what specialist assistance might be available to them in their investigations, and I have therefore written to a number of institutions asking if and how they are able to help. But the committee would also like to hear from any individuals and other organisations who feel they have the individuals and other organisations who feel they have the necessary expertise, and I am therefore seeking the hospitality of your columns to make this request.

Yours faithfully,

CHRISTOPHER PRICE MP

House of Commons, London UK

Research councils: do they pay the real cost?

SIR, — I should like to publicise an unfortunate consequence of the restrictions which grant-awarding bodies such as the Science Research Council place on the use to which their grants may be put. In general the recipient is not allowed to use the money to pay for computing, telephoning, typing, photocopying, page charges for publishing, library facilities, recruitment advertising, removal expenses for staff appointed, or redundancy pay. Instead, the host institution is assumed to be capable of paying for all of these. This is unquestionably no longer true. The result of this is that the more active a department or institution is, the closer it is brought to bankruptcy by its scientific endeavour. I would suggest that small institutions are particularly vulnerable to this. Is it not about time that the research council faced up to their responsibility and paid the *full* cost of a research project? Is it really our government's policy to encourage its academic scientists to lay low and do nothing because the funds provided are not sufficient to cover the *real* cost of their projects?

Yours faithfully,

ALAN D.B. MALCOLM

St Mary's Hospital Medical School, London UK

X as the Y of Z

SIR, — In your review of Horace Judson's *The Eighth Day of Creation* (11 October, page 506) I am called "a sort of Louella Parsons of molecular biology" apparently, because I told Judson that I thought a friend of mine is its Douanier Rousseau (a painter whom I very much admire). Here your reviewer is not far off the mark: long ago I picked up the habit of styling X as the Y of Z at a party in Hollywood, where I heard Christopher Isherwood say that Wagner is the Puccini of music.

Before finally kicking the habit, may I coin one final simile? Namely, if *The Eighth Day of Creation* really showed as much lack of historical comprehension as your reviewer found it to show, then Judson would be the Thomas Jukes of molecular biology.

Yours faithfully,

GUNTHER S. STENT

University of California, Berkeley, US.

Mutants in a mosaic gene reveal functions for introns

from Bernard Dujon

Two years ago molecular geneticists discovered an unexpected organisation for eukaryotic genes: the DNA sequences that specify the primary structure of the gene product (often called exons[1]) are interrupted by other base sequences (called introns or intervening sequences). The origin and the significance of the latter remain a puzzle (see ref. 2). However, one might hypothesise that the different alternating pieces of the same gene, the introns and the exons, could perform different genetic functions recognisable with the help of specific mutations. A mitochondrial gene of the baker's yeast seems to provide an example of this.

After mutations in the mitochondrial gene for cytochrome b, an enzyme of the respiratory chain, were first reported about three years ago[3-5], it soon became apparent that they result in a wide diversity of phenotypes[6, 7]. Some of them are even pleiotropic and also block the synthesis of the subunit 1 of cytochrome oxidase, another element of the respiratory chain whose gene is in another part of the mitochondrial genome. By a combination of genetic and molecular methods[8-11,16] and by a laudable collaborative effort between different groups of investigators, all the mutants (around 200) are now ordered in a unique map[12].

The idea that the cytochrome b gene is a mosaic[13] of, at least, five exons interspersed with four introns is suggested by the following lines of evidence. (1) There is a consensus that the gene product is the 30,000 molecular weight polypeptide, from specific labelling of the mitochondrial translation products[10,14-16]. However, mutations affecting cytochrome b span a region of the mitochondrial DNA which is several times larger than needed to code for this polypeptide and are highly clustered (refs 9, 11, 12 and Fig. 1). (2) The smallest transcript found in this region of the map (2.3 kilobases) and believed to be the mature messenger RNA for the cytochrome b[20-22], hybridises with non-contiguous segments of DNA[20] whose positions and sizes are consistent with expectations from the genetic and physical map. (3) With some mutants the 30,000 molecular weight polypeptide is replaced by a single new polypeptide usually smaller than the wild type[14, 16, 18] as if premature chain termination had occurred. Colinearity[13] between the size of the new polypeptide synthesised and the location of the mutants on the map strongly suggests a single translation unit. This is confirmed in double mutants by an epistatic effect of the upstream mutation on the downstream one[18,19]. (4) With other mutants, interspersed among the first ones, a series of new polypeptides appears in the range of about 15,000 to 60,000 molecular weight[14, 16, 18], suggesting that translation now proceeds also through sequences not normally translated. Peptide mapping confirms that for most cases the new polypeptides do share sequence homologies with the wild type protein[16, 17].

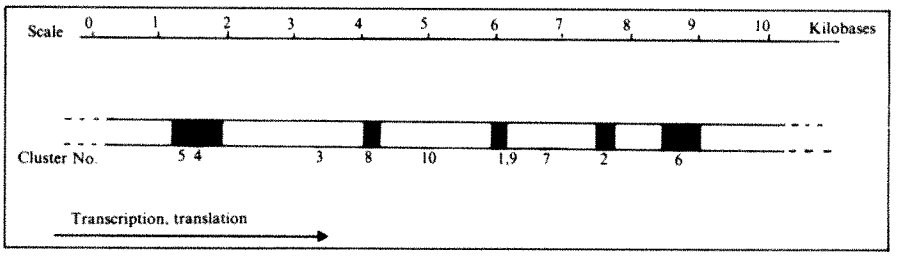

Fig. 1 The cytochrome b gene is a mosaic of at least five exons (black) interspersed with four introns (white). Mutants can be found in both (cluster No). They have been mapped as indicated by a combination of genetic and molecular methods.

A unique contribution of the yeast cytochrome b gene to the more general question of the expression and regulation of eukaryotic split genes lies in one's ability to perform functional complementation tests between mutants. On the basis of this test the mutants fall into two classes[9, 19]. The first is composed of mutants that fail to complement one another (they belong to the clusters 5, 4, 8, 9, 1, 2 and 6; numbering is historical and not logical). Those therefore are satisfactorily explained by the classical notion of cistron and they are called here 'exon mutants'. The idea that they are mutants in exons is confirmed by the fact that drug resistant mutations, affecting the sensitivity of the protein to specific inhibitors but not its activity, are closely linked to them[23, 24]. Now, most 'exon mutants' can be complemented in *trans* by the mutants of the second class (clusters 3, 10 and 7). Thus, mutants of the second class, although interspersed among those of the first, do not belong to the same cistron. Instead, each cluster constitutes a new complementation group. In a mosaic gene the classical notion of the cistron must therefore be accommodated with the fact that some mutations in the continuity of a given cistron will not belong to that cistron, as if different mutants affected different types of functions. Mutants of the second class are described in the literature as 'intron mutants'. Such a definition only refers to the functions altered in the mutants. The location of these mutants within long introns can eventually be established by molecular mapping[9,11]. These mutants therefore suggest a specific role for introns. Interestingly, they show the pleiotropic effect on cytochrome oxidase.

The next refinement in complementation studies was achieved by experiments in which the exons of the two parents are distinguished from each other by the use of the drug resistant mutations as genetic markers. From a series of such experiments performed recently[25] it became clear that the 'exon mutants' can provide in *trans* a function that helps overcome the deficiency(ies) of the 'intron mutants', such that the final gene product can be made using the non-mutated exon sequences of the 'intron mutants'. Consistent with the fact that 'exon mutants' are a unique cistron, all the exons are now always expressed in *cis*. This is diagrammatically shown in Fig. 2. Similarly different 'intron mutants', belonging to two different clusters, can help each other such that both will now be able to express normally their non-mutated exon sequences.

Bernard Dujon is Chargé de Recherches au CNRS (France) and at present a Research Fellow at Harvard University.

© 1979 Macmillan Journals Ltd

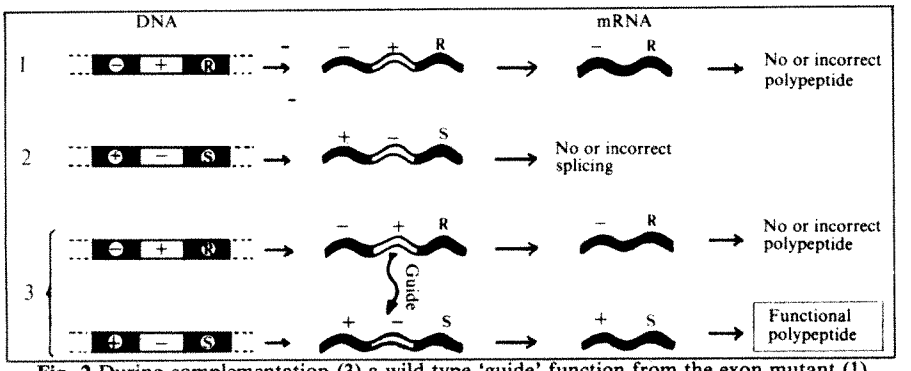

Fig. 2 During complementation (3) a wild type 'guide' function from the exon mutant (1) helps overcome the splicing deficiency of an intron mutant (2) whose non-mutated exon sequences are then used to direct the synthesis of the polypeptide. The 'guide' step is arbitrarily shown as an interaction between two mRNA precursors but could be otherwise.

All the properties of 'intron mutants' reflect a deficiency in a gene function, different from the coding of the primary sequence of the protein, and required at an earlier step than translation. From this we hypothesise a deficiency of RNA splicing. This is directly confirmed by examination of the RNA transcripts showing that 'intron mutants' are actually blocked at different specific steps of splicing[21,22]. Correct RNA splicing therefore would require wild type sequences which, when mutated in a given gene, can be complemented in *trans* by products of another copy of the same gene. This prompted P. Slonimski to propose a new element for gene expression called 'guide RNA'[21,26], whose role is to align the splice junctions or to pull out the skein of messenger RNA precursor for proper splicing to occur. The guide concept is based on the *in vivo* complementation test and is necessary to explain the results. The idea that such a guide role is played by an RNA molecule, and not a protein, is not yet directly demonstrated. But it opens the possibility that successive processing of the different introns could serve as a mechanism for regulating gene expression. Such schemes are now being proposed[21,22].

In those the completion of one step requires the success of a previous step, as if proper splicing of one intron created the guide needed for the splicing of another. The same scheme applies to explain the pleiotropic effect of some 'intron mutants' on the cytochrome oxidase gene[21].

If such a guide exists one would like to know the nature of the sequences involved, their relations to introns, exons or junctions and the molecular form of the guide (for example, is it free spliced intron RNA or part of the precursor). Similarly the mechanism of guidance (for example RNA/RNA base pairing or more complex interactions) is a question for investigation. In addition, the interaction of some mutants of the cytochrome oxidase gene on the expression of cytochrome b[21, 27] may also be a very promising avenue for study. One can then reasonably guess that in the near future an ordered regulatory scheme of splicing of these two genes, assigning specific functions to specific sequences, will be available. Now, what in the genome of mitochondria reflects a high degree of specialisation and what a more general pattern for eukaryotic genes, remains as yet unknown. But, in any case, the cytochrome b gene immediately provides functions for introns that are directly amenable to experimental analysis. □

Flight formations in geese and other birds

from Robert M. May

AMONG the autumn sights around Princeton are the V-shaped formations of Canada geese, *Branta canadensis*, honking across the sky in flights of up to 100 birds.

It has often been suggested that the purpose of this tidy formation is to take advantage of aerodynamic efficiencies which can accrue to group flight. Figure 1 (from Lissaman & Shollenberger, *Science* **168**, 1003; 1970) illustrates how these effects come about. As these authors explain, the downdraft under the bird (the downward pointing arrows) derives from the "basic principle of aerodynamics that an object flying by dynamic lift in a fluid gets its lift by creating downward momentum within its span. This applies to fish or fowl, airplane or submarine.". Beyond the wing there is an upwash, which is very intense near the wingtip and which is associated with conservation of momentum in the fluid. The resulting streamlines are as depicted in the left half of Fig. 1; these streamlines show the direction of airflow generated by the passage of the bird, and we see they have a general tendency to produce an updraft to the right and left of the bird, and a downdraft above and below it. Thus birds flying side-by-side can take advantage of the updrafts from neighbours, an effect similiar to flying in an upcurrent, with a consequent reduction in the 'lift power' needed. Conversely, birds flying in a vertical column would each need to generate additional lift to compensate for the downdraft effect.

In a quantitative analysis of the magnitude of these effects, Lissaman and Shollenberger have shown that a formation of around 25 or more birds can reduce the power required for 'lift' by a factor of 2.9 by flying wingtip-to-wingtip in a horizontal line. For a given power output, the increase in range scales as the square root of this lift-reduction factor; thus flight formations of 25 or so birds can have a range roughly 70% greater than that of a lone bird. The associated optimum cruising speed decreases as the inverse fourth root of the lift-reduction factor, corresponding to a 24% reduction in the speed of the formation compared with a lone bird. These calculations take into account the effects of lift (or, in aeronautical jargon, 'induced drag') and of the power needed to overcome direct air resistance ('profile drag'), but they ignore the complications of flapping wings. The flapping losses are likely to be negligible so long as the wingtip flapping speed is significantly less than the

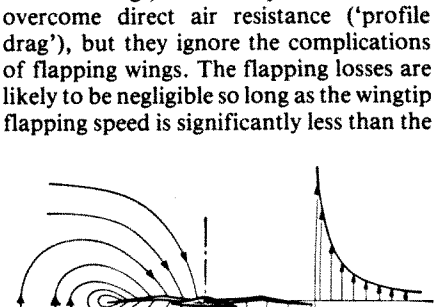

Fig. 1 Flow field associated with a flying bird.

forward flight speed; this is so for geese, but is not always true for the passerines discussed below.

The basic calculation of Lissaman and Shollenberger is for a horizontal formation of birds advancing in line abreast. But 'Munk's stagger theorem' states that in a classical fluid (where circulation is conserved) any member of an assembly of lifting surfaces may be translated in the direction of its flight path without changing the total induced drag. Now, in the line abreast formation the end birds enjoy relatively less, and the centre birds relatively more, of the upwash; indeed, with more than ten birds, the central birds have double the savings of the end ones. By staggering the formation into a V, the induced drag can be shared evenly, without affecting the total for the formation. The V does this by virtue of the lead bird experiencing a weaker upwash field even though it is mainly on one side. In detail, the 'optimum' configuration is like a slightly rounded V, with a blunted point and more acutely trailing tips. For a formation of nine birds, Lissaman and Shollenberger's calculations suggest the angle of the V to be roughly 120°. The formation has, moreover, a kind of stability in that a bird forging ahead will tend (under constant power) to fall back, and a bird dropping back will tend (under constant power) to catch up; more subtly, the formation is not stable against a bird which drops back and reduces power.

Canada Geese flying

Gould and Heppner (*Auk* **91**, 494; 1974) have attempted to test these ideas, by analysing films showing formations of Canada geese in North America. They made observations of more than 100 flights of flocks, averaging around 27 geese. The first disconcerting observation was that over 40% of the formations were echelons, wherein the lead bird must enjoy significantly less than the average updraft. Moreover, in the five cases where the data yielded a steady result, they found (after correcting for the distortions created by viewing the formation from the ground and at an oblique angle) an average V-angle of 35°. Gould and Heppner also find other V-angles of 31° and 36° mentioned in the literature, by people who chanced to see flocks directly overhead. They also report unpublished radar observations by Williams, Klonowski and Berkeley, which give an average V-angle of 71°. (The radar data were collected in the spring, the others in the autumn, and in all cases the geese were flying from feeding to roosting grounds, rather than being in long-distance migration.) In short, almost half the formations were echelons, and those that were V-formations had angles consistently much less than Lissaman and Shollenberger predicted on the basis of equalisation of uplift among the birds.

Gould and Heppner conclude that aerodynamic effects are not the main reason for V-formations, and suggest other explanations (such as the birds keeping each other in view). I think this conclusion is too strong. Another piece of the information elegantly gathered by Gould and Heppner is the spacing of birds along the arms of the V, which ranges from 3.2 m to 4.7 m for different V-angles. The key distance, however, is this spacing projected along the line of flight (that is, the equivalent line-abreast spacing), which averages about 1 — 1.5 m, or around the wingtip-to-wingtip distance (approximately 1.5m) that gives maximum overall lift. This arguably is the main phenomenon, and its total magnitude is (according to Munk's stagger theorem) independent of whether the flock flies in line abreast, in echelon, or in a V of arbitrary angle. The question of equalising the advantage among the birds is a much subtler one, and evokes echoes of similar questions about the "geometry of the selfish herd" (Hamilton, *J. theor. Biol.* **31**, 295; 1971), where aggregation does confer some overall benefits on the herd, but where at any one moment these benefits are enjoyed more by the inner than by the outer members. It would be interesting to know if the disadvantaged lead goose keeps the lead for long periods, or whether the lead continually shifts.

The preceding discussion pertains to horizontal line formations, as are found in geese. But many other species of birds conduct their long twice-yearly migrations in large three-dimensional flocks. This is the case for most migratory passerines. Higdon and Corrsin (*Am. Nat.* **112**, 727; 1978) have analysed the net aerodynamic advantage associated with such flock-flying, as a function of the overall shape of the flock. If the average separation between birds is reasonably large compared to the wingspan of an individual bird, an elegant nineteenth-century-tripos-style calculation is possible, regarding each bird as a dipole vortex and summing over all birds. For a two-dimensional flock of such birds, randomly arranged within a vertical ellipse of height B and width A, the flock-associated decrease in induced drag (or upwash) on each bird, expressed as a ratio to the induced drag in sole flight is

$$(\pi^3/64)nd^2(A-B)/(A+B). \qquad (1)$$

Here n is the average number of birds per unit area and d is the wingspan; thus nd^2 can be rewritten as $(d/\Delta)^2$, where Δ is the average spacing between birds. (The expression (1) differs from Higdon and Corrsin's by an unimportant numerical factor of 4, which they lose in the process of making a sequence of unnecessary approximations.) The maximum aerodynamic advantage is obtained when the horizontal extension of the flock greatly exceeds the vertical ($A \gg B$), whereas if the vertical dimension exceeds the horizontal one ($B > A$), the net effect is an increased downdraft. This general observation does not depend on the detailed shape of the flock, and it follows broadly from the earlier discussion

0028-0836/79/510779-01$02.00

© 1979 Macmillan Journals Ltd

associated with Fig. 1. We can see that, unless the birds fly closer together than observations suggest, the aerodynamic effects of such flight in two-dimensional flocks is slight; even if the spacing between birds is as little as twice the wingspan ($\Delta \sim 2d$), the uplift effect in a horizontally extended flock is only around 10%. Higdon and Corrsin estimate the corrections to equation (1), in the event of the birds flying in some ordered lattice pattern, rather than more-or-less randomly. These correction terms are of order n^2d^4; that is, they are smaller than those given in equation (1), by a factor of order $(d/\Delta)^2$.

Extending the analysis to encompass a fully three-dimensional flock is in principle straightforward (by virtue, again, of Munk's stagger theorem, which enables the three-dimensional problem to be projected into a two-dimensional one). In a randomly arranged flock, the upshot will be to regain the expression (1), but with n now being the average number of birds projected onto unit area perpendicular to the flight direction. Clearly, the result will be to increase the uplift effect (1) as n increases, provided the flock is extended more horizontally than vertically. If the effective value of n becomes too large (so that nd^2 is not appreciably less than unity), the 'dipole vortex' approximation will begin to break down, and the computations must be based on pairs of vortices centred at a bird's two wingtips. But for most three-dimensional flocks of migratory birds the density is unlikely to make this refinement necessary. I take home the message that three-dimensional flocks of passerines and other birds can gain non-negligible updraft effects, provided the flock is extended more horizontally than vertically, but that the magnitude of the effect is not nearly as large as that gained in the close, horizontal line formation of geese.

A different kind of insight into the dynamics and ergonomics of migratory flight comes from Allerstam (*J. theor. Biol.* **79**, 341; 1979). Starting with the observation that wind speed is usually less at low than at high altitude, he examines the idea that migratory birds may save flying time and energy by allowing themselves partly to be drifted by strong winds at high altitude, and then correcting their course at low altitude in relatively weaker winds. For typical values of wind velocities, Allerstam's calculations suggest this behaviour will be advantageous if the strong upper winds are blowing in a direction roughly 30° to 90° wide of the goal direction ('following side winds'). If the wind is blowing at an angle less than 30° to the desired direction, a direct high altitude flight is optimal. Conversely, a direct low altitude flight is the best route against a headwind (in excess of 90° wide of the goal direction). Allerstam concludes with a survey of the available evidence, of which the best (Gruys-Casimir, *Arch. Neerl. Zool.* **16**, 175; 1965) is on chaffinch migration in Holland: "Radar observations of drift in high altitude bird migration and visual records of low altitude overcompensation are compatible with the optimal flight behaviour of migrants at high and low altitude, respectively, as predicted from this hypothesis." □

Mycorrhizal associations

from Peter D. Moore

MYCORRHIZAL associations between plant roots and fungi are now known to be extremely common in nature. It is evident that such associations are symbiotic, both parties benefitting from the interaction. As far as the plant is concerned, the association may be very costly in terms of the loss of fixed carbon to its heterotrophic partner. Lewis and Harley (*New Phytol.* **64**, 256; 1965) fed ^{14}C sucrose to cut roots of beech (*Fagus sylvatica*) and observed that 50–75% of the carbon reaching the root tip was passed on to the mycrorrhizal fungus, which obviously represents a considerable drain on the photosynthetic resources of the plant.

The widespread occurrence of mycorrhizae, however, witnesses to the evolutionary value of the partnership to host plant as well as fungus. It has long been established that a major advantage to the plant is the greater efficiency with which it is able to absorb necessary inorganic materials from the soil (Harley *J. Ecol.* **59**, 653; 1971). There is also some evidence to suggest that water uptake is assisted by mycorrhizal infection (Safir *et al. Plant Physiol.* **49**, 700; 1972). This being so, one might expect mycorrhizal associations to be of particular value, and therefore especially prevalent, in habitats deficient in plant nutrients and water.

Grime (*Plant Strategies and Vegetation Processes*, 36; Wiley, Chichester, New York, 1979) takes up this argument in his discussion of stress-tolerant plant species. Grime proposes an ecological classification of plants into competitors, stress-tolerators and ruderals, and he claims that mycorrhizal associations, particularly of an ectotrophic type, are to be expected amongst plant species adapated to nutrient stresses. Data recently published deriving from arid regions of the United States support and extend this view.

Reeves, Wagner, Moorman and Kiel (*Am. J. Bot.* **66**, 6; 1979) have conducted a survey of vesicular-arbuscular (endo-) mycorrhizae in semi-arid sagebrush communities of Colorado. Of the 42 species of plant present, only 2 were found to lack mycorrhizal infection, one chenopod and one crucifer. This emphasises the widespread nature of mycorrhizae in a taxonomically diverse flora: 13 families are represented and all but one have mycorrhizal members present.

The authors also investigated a nearby site which had been severely disturbed by road construction. Here 21 plant species were growing, but only 6 possessed mycorrhizal infections; these species had also been present in the undisturbed site. The remaining 15 species were confined to the region of disturbance and had no detectable mycorrhizal infection (three individuals of each species were examined). Thus, in an unstable habitat, the mycorrhizal plants could be at a disadvantage, perhaps because of the destruction of a large proportion of the residual fungus in the soil during the process of disturbance which might restrict recolonisation by mycorrhizal species of plants. The authors propose that early successional stages are deficient in mycorrhizal species, whereas in later, more stable stages the vast majority of species are so adapted. This seems to be justified for their arid, nutrient-poor habitat.

The lack of mycorrhizal species in disturbed sites is confirmed by the results of a similar investigation by Miller (*Can. J. Bot.* **57**, 619; 1979) of mine spoil heaps and nearby undisturbed sage scrub in Wyoming. In these latter, pristine areas, 21 species were examined and only one lacked vesicular-arbuscular mycorrhizal infection. On the spoil heaps 16 species were found, none of which was infected. Even within one family, the Chenopodiaceae, some members are non-mycorrhizal and ruderal in habit, whereas others (the majority) are mycorrhizal and are found in undisturbed habitats where edaphic stresses of nutrient and water availability are encountered.

So the Grime hypothesis seems to hold true for these semi-arid ecosystems: there does appear to be a division among plants which corresponds to his stress-tolerant and ruderal types. What is not clear from these particular sites is the outcome of low disturbance and low stress. In other words, of what importance are endomycorrhizae to the Grime competitor? □

100 years ago

M.A. Guyard claims to have discovered another new metal of the platinum group which he names uralium, from the Ural Mountains, whence the ore is procured. There have been quite a flood of similar announcements lately. We have now gallium, davyum, mosandrum, neptunium, decipium, phillipium, norvegium, scandium, ytterbium, holmium, "X", thulium, and uralium. Chemists will have to keep as narrow a watch on these minor elements as our astronomers do upon the minor planets, or we shall not know where we are.

The transforming genes of SV40 and polyoma

from Peter Rigby

SIMIAN virus 40 (SV40) and its relative polyoma (which naturally infects mice) are small DNA viruses which have relatively simple genomes that provide attractive and easily manipulated systems for probing the mechanisms of eukaryotic gene expression. They have also attracted great interest because of their ability to transform some mammalian cells *in vitro*. Such transformed cells have many of the properties of tumour cells and have been studied in the hope of elucidating the mechanisms by which viral gene expression can over-ride the normal controls on cell growth and behaviour. During the past few years great progress has been made in defining the viral genes and their products responsible for transformation. It has been known for some time that the so-called 'early' region (those genes expressed soon after infection and before viral DNA replication in cells in which the virus is able to multiply) is sufficient to induce transformation. Work on the transforming capacity of SV40 and polyoma has therefore focused on defining the products of the early region, and recently published work, together with results presented at two meetings* last summer, have greatly increased our understanding of the structure of this region and of the properties of its protein products.

The availability of complete DNA sequences for both SV40 and polyoma[1-8] has enabled the relationship between the various protein products of the early region, classically identified by immunoprecipitation with sera from animals bearing virus-induced tumours, to be clarified. Originally only one such SV40 'tumour' antigen (T-antigen) was recognised. This is a protein of apparent molecular weight 100,000, now called large T-antigen; a protein of this size would account for almost all the coding capacity of the early region. Prives *et al.*[9] then showed that among the products of *in vitro* translation of viral mRNA obtained from infected cells was another immunoprecipitable protein of molecular weight 17,000 — the small t-antigen.

Large T/small t

The first clue to the origin of small t came with the discovery of viable SV40 deletion mutants that produce normal large T despite the fact that the deletions are within the sequence that was thought to code for this protein[10]. However, these mutants do not induce the synthesis of full size small t[11] and transform cells at a reduced frequency under certain assay conditions[12,13]. At about the same time Berk and Sharp[14] showed that there were two SV40 early mRNAs and not one as had previously been thought. These mRNAs have the same 5′ and 3′ ends but are spliced differently (see Fig. 1). The smaller of the two early mRNAs encodes large T[15]; the sequences missing in the viable early deletion mutants correspond to those normally spliced out of this mRNA and so the protein is unaffected. In the other mRNA fewer nucleotides are removed by splicing and the additional mRNA sequences contain an in-phase termination codon. Thus this message directs the synthesis of small t[15]. The relationship between the two tumour antigens shown in Fig. 1 has been confirmed by peptide mapping and sequencing studies[16-19].

The analogous polyoma mutants, known as *hr-t* (host range-transformation) mutants, were isolated many years ago by Benjamin[20] and are absolutely defective for transformation. *hr-t* mutations, which can be either deletions or point mutations, map in the region of the polyoma genome analogous to that deleted in the viable early deletion mutants of SV40[21,22] and it was shown that polyoma also encodes a small t which is affected by *hr-t* mutations although the large T remains normal[23,24].

Polyoma middle T-antigen

Immunoprecipitation of extracts of polyoma-infected and transformed cells with anti-tumour serum has identified a third tumour antigen, of molecular weight 55,000 — middle T-antigen[25]. This is found in association with the plasma membrane and probably has the same amino-terminal sequence as small t and large T[26-28]. But peptide maps show that middle T contains peptides found in neither of the other two tumour antigens suggesting either that it is translated in a different reading frame or that it is partially coded by the host cell[26,27]. However, the mRNA for middle T hybridises specifically to polyoma DNA[29], this protein as well as small t is altered by *hr-t* deletions[24,28] and examination of the polyoma DNA sequence reveals the presence of a second open reading frame in the appropriate part of the early region.

SV40-transformed cells contain an immunoprecipitable protein of similar molecular weight, 53,000, and it was initially thought that this might be the analogue of polyoma middle T. The relevant region of the SV40 genome, however, contains only one open reading frame, that used for large T, and it is now clear that this protein, which is discussed in more detail below, is of cellular origin.

Organisation of integrated viral DNA

In cells transformed by SV40 or polyoma, viral DNA is covalently integrated into the chromosomal DNA of the host cell and the expression of this viral information is responsible for the transformed phenotype. There is a great deal of new information on the organisation and expression of these integrated sequences which is helping to identify the roles of the different tumour antigens in transformation. The organisation of the integrated viral DNA in many transformed mouse and rat cell lines has been analysed by restriction mapping. The general conclusion is that integration is not specific, each line has a characteristic pattern of virus-specific DNA fragments indicating that many different sites on both viral and cellular DNAs can be used for integrative recombination[30-33]. However, F. Cuzin (Nice) has reported that identical integration patterns are observed in two sets of SV40-transformed cells, one set of three rat lines the other of two mouse lines. There are distinct biological differences between the three rat lines but in view of the preponderance of data suggesting random integration the significance of these observations is unclear.

The structure of the integrated viral DNA can provide clues to possible mechanisms of integration. A high proportion of SV40 and polyoma-transformed cell lines carry tandem duplications of all or part of the viral genome[32,33]. Such structures would not be expected if recombination occurs between monomeric, circular viral DNA and linear chromosomal DNA. However, P. Rigby (Imperial College, London) discussed data indicating that SV40 DNA replicates in mouse cells to produce large, tandemly-arrayed polymers of viral DNA and that these polymers recombine effectively with one another. If such polymers are the precursors of the integrated form the high frequency of tandemly-duplicted insertions would be explained. When some transformed cells are fused with permissive cells infectious virus can be rescued and in certain cases the DNA of the rescued virus is identical in structure to that of the virus used to transform the cells. Such perfect excision may well result from the presence of tandemly-duplicated insertions and the loss of a complete copy of the viral genome from a tandem array has been demonstrated in some polyoma-transformed lines[34]. However, excision does not require tandem duplication; when the transformed rat cell line 14B, which carries a defective copy of the viral genome, is fused with permissive cells imperfect excision occurs giving rise to a heterogeneous population of circular molecules containing both viral and cellular sequences (M. Botchan, Cold Spring Harbor Laboratory, New York). Some of these rescued DNAs have been cloned and sequence analysis shows that the structure of the viral-cellular joins is unaltered. It has been proposed that this type of excision may proceed by way of *in situ* replication of the integrated viral

sequences rather than by a recombinational excision[35].

J. Sambrook and J. Stringer (Cold Spring Harbor Laboratory, New York) described the cloning of the single integrated SV40 genomes of two transformed rat cell lines. In one line, 14B, the integrated sequences are not colinear with free viral DNA; one segment of the genome has been deleted while another is inverted, giving a structure that Sambrook suggested could be derived from recombination between cellular DNA and a replicative intermediate of viral DNA. The cellular-viral DNA junctions in this line have been sequenced; there is no detectable homology between the viral DNA and the cellular DNA into which it is integrated suggesting that integration occurs by illegitimate recombination. The cellular sequences flanking the integrated viral DNA have been compared in detail to those flanking another integrated viral genome that has been cloned, from line 17, and there are no detectable similarities or sequence homology.

T antigens and transformation

Although there is much evidence to implicate large T in transformation by SV40, elucidation of the structure of the integrated viral DNA in polyoma-transformed cell lines suggests that polyoma large T is not essential for transformation. Some polyoma-transformed cell lines do not carry complete copies of the early region; although such lines may have tandemly duplicated insertions each copy of the early region is interrupted, either by a deletion or by a virus-host junction, in such a way that there is no complete coding sequence for large T (M. Fried & L. Lania, ICRF, London). Analyses of the mRNAs (R. Kamen, ICRF) and of the tumour antigens present in such lines confirm that they contain small t and middle T but not large T, although in some lines truncated derivatives of large T are present.

More direct evidence that polyoma transformation does not necessarily require intact large T is provided by experiments in which viral DNA, either intact or cleaved by restriction endonucleases, is injected into newborn hamsters[36]. If the DNA is cleaved to interrupt the early region coding sequences unique to large T, tumorigenicity is increased over that of supercoiled intact DNA and cell lines established from the resultant tumours contain only small t and middle T. It might be argued that large T is produced from uncleaved or recircularised DNA during the initial stages of tumour induction. This possibility has been eliminated by experiments in which hamsters are injected with a recombinant plasmid containing polyoma DNA cloned through its *Eco*RI site, which lies within the unique large T coding sequence, into the *Eco*RI site of pBR322 (M. Martin & M. Israel, National Institutes of Health, Bethesda). Tumours were obtained and cell lines established from them. Such lines lack large T and analysis of the DNA of one of them shows that the integrated DNA retains the two polyoma-pBR322 joints. J. Hassell (McGill University, Montreal) reported data showing that cloned fragments of polyoma DNA that contain the coding sequences of small t and middle T, but lack almost all the sequences unique to large T, will transform cells *in vitro* and that the resulting cell lines have a standard transformed phenotype. Further confirmation of the role of the various tumour antigens in polyoma transformation is provided by an experiment in which rat cells were infected with an *hr-t* mutant and cell lines were established from clones picked at random[37]. One such line contains the genome of the *hr-t* mutant in both free and integrated forms. The cells synthesise large T but not small t nor middle T; they have a normal phenotype *in vitro* and will not induce tumours *in vivo*, showing that large T itself is insufficient to maintain the transformed state. Mutants of polyoma with deletions in the region coding for both middle T and large T have altered transformation properties[38] and some of the cell lines that are isolated do not have all the characteristics of a fully transformed cell (B. Griffin, ICRF). When taken together these data imply that only half of the early region is required to initiate and maintain transformation and suggest that middle T may be the most important protein for this process.

Temperature-sensitive polyoma mutants of the *ts-a* class map in the region coding uniquely for large T[39,40] and it was shown many years ago that, at the non-permissive temperature, such mutants are defective for the initiation but not for the maintenance of transformation[41]. It may well be that in a normal virus infection large T is required to initiate transformation, perhaps because integration requires viral DNA replication, as has been suggested for SV40. Transformation with DNA involves the cells receiving massive doses and in such cases other integration mechanisms, not dependent on DNA replication, may operate. What is clear is that polyoma-transformed cells can retain their phenotype in the absence of intact large T, whereas all SV40-transformed lines examined so far retain and express all of the large T coding sequences. The difference between the two viruses presumably reflects the fact that polyoma has evolved a third early protein, middle T, which SV40 does not have.

Polyoma transcription

The transcription of the early region of polyoma DNA has been studied in great detail by Kamen and his colleagues. Their powerful two-dimensional modification of the Berk and Sharp S1 endonuclease mapping procedures reveals three major mRNAs in productively-infected cells (see Fig. 1) which presumably code for the three tumour antigens. The mRNAs for small t and large T have a similar relationship in both polyoma and SV40. Fitting the S1 mapping data to the DNA sequence indicates that the mRNA for middle T is derived by splicing the leader of small t mRNA to a body that begins some twelve nucleotides downstream of the body of small t mRNA, thus eliminating the termination codon used for small t and effecting the change in reading frame necessary to produce middle T. Polyoma-infected cells also contain a minor class of mRNAs, containing representatives of all three splicing patterns, the 3′ ends of which map close to the middle of the early region, just past the termination codon for middle T.

In polyoma-transformed rat and mouse cells the 5′ ends of the mRNAs correspond

0028-0836/79/510782-01$02.00

© 1979 Macmillan Journals Ltd

to those found early in productively-infected cells, suggesting that transcription is initiated at the viral rather than a host cell promoter. Almost all transformed cell lines overproduce the shortened mRNAs that have polyadenylated 3′ ends mapping in the middle of the early region and in one mouse line the vast majority of the viral mRNA terminates at this site, although the virus-host junction in the integrated DNA is 0.75 kilobases further downstream. There has been much speculation regarding the existence in transformed cells of fused virus-host transcripts. The integrated viral DNA from one mouse line, *ts-a*3T3-3, has been cloned in λ (Fried) and Kamen's group have mapped the mRNAs against this isolated DNA segment. Their data show clearly that the polyadenylated ends lie some 60 nucleotides into the cellular DNA at the 3′ end of the transcription unit, thus providing the first definitive evidence for fused transcripts.

SV40 transcription

Transcription in SV40-transformed cells has not yet been analysed in the same detail. Sambrook reported that the mRNAs of the rat lines 14B and 17 had been mapped against the cloned integrated genomes using the S1 endonuclease method; they seem to be identical to the two early transcripts found in productively-infected cells. However, M. Lovett (Imperial College, London) presented transfer hybridisation experiments[42] showing that in several mouse lines novel transcripts, both larger and smaller than those found in infected cells, can be detected. One line contains derivatives of both small t and large T mRNAs that extend past the normal viral polyadenylation signal but it is not clear whether they terminate at a viral or a cellular site. E. May (IRSC, Villejuif) discussed S1 mapping data suggesting that some rat lines synthesise mRNAs which contain tandem duplications of viral sequences coding for large T. *In vitro* translation of such transcripts shows that they encode very large proteins related to large T; these super T-antigens are quite widespread[43-45]. Peptide mapping indicates that in some cases super T proteins contain peptides from the C-terminal half of large T in more than one molar yield (F. Chaudry, ICRF) suggesting that the amino acid sequence is also tandemly duplicated.

A cellular protein associated with T-antigens in SV40-transformed cells

As well as the virus-coded T-antigens SV40-transformed cells contain an immunoprecipitable protein of molecular weight 53,000, the so-called nvT-antigen (non-viral T-antigen). Peptide analysis shows that this protein is unrelated to small t or large T and that it is different in transformed cells of different species[43-45]. It has also been found in uninfected mouse 3T3 cells and undifferentiated mouse teratocarcinoma cells[46,47]. Its synthesis is induced by SV40 infection and this induction requires the activity of large T[47]. In extracts of transformed cells nvT cosediments with the polymeric, highly-phosphorylated form of large T (F. McCormick, ICRF). These experiments confirm the proposition, first advanced by Lane and Crawford on the basis of immunological experiments[48], that nvT is precipitated by anti-tumour serum because it exists intracellularly as a complex with large T. G. Jay and E. Appella (NIH) reported that a 53,000 molecular weight protein, which may be identical to nvT, is recognised by antisera raised against methylcholanthrene-induced mouse sarcomas and that this protein is expressed in cells transformed by many agents including SV40. It is found in chemically-induced sarcomas, leukaemias induced by either X-irradiation or Moloney murine Leukaemia virus, in cells transformed by the Moloney or Kirsten strains of murine sarcoma virus and in spontaneously-transformed fibroblasts. The protein is also detectable in undifferentiated F-9 teratocarcinoma cells but not in normal 3T3 cells, primary embryo cells, adult lung fibroblasts, haematopoietic cells or lymphoid cells. Most interestingly the protein is present in normal thymus cells which have an extremely high mitotic rate and it appears to be synthesised only at particular stages of the cell cycle. It is tempting to speculate that nvT is involved in the control of cellular DNA replication and that complex formation between it and large T is part of the mechanism by which the virus over-rides the normal control of cellular DNA replication.

T antigens as enzymes

The enzymatic function(s) of the papovavirus T-antigens continues to be somewhat controversial. Following the demonstration that the transforming protein of the RNA tumour virus Rous sarcoma virus (RSV) has protein kinase activity[49] several groups reported that SV40 large T has a similar activity[50,51]. However, R. Tjian (University of California, Berkeley), working with the hybrid protein encoded by the adenovirus-SV40 hybrid D2, now claims that the kinase activity can be separated from the D2 T-antigen by purification procedures which do not separate the ATPase activity also associated with this protein. Glycerol gradient centrifugation experiments show that the ATPase binds well to SV40 DNA, a property expected of an activity of large T which binds to the viral origin of DNA replication[52,53], whereas the kinase binds rather poorly. Tjian has now isolated large T from SV40-infected monkey cells; although it has not been purified as extensively as the D2 protein, 99.9% of the kinase activity can be separated from the large T is two chromatographic steps. Moreover, large T isolated from cells infected with *tsA* mutants has a thermolabile ATPase activity but the removed kinase is thermostable. L. Hager (University of Illinois, Urbana) also reported work indicating that large T has an ATPase activity that is stimulated by oligo(dT) but that it is not a kinase.

However, D. Livingston (Harvard University) presented data indicating that highly purified preparations of large T from transformed human cells do have a kinase activity and that the protein isolated from cells infected with *tsA* mutants is temperature-sensitive for the transfer of phosphate to casein. The situation remains confused but it seems that the identification of SV40 large T as a protein kinase is somewhat suspect. It may be unreasonable to expect the enzymatic activities of the transforming proteins of SV40 and RSV to be the same, particularly as large T is predominantly nuclear whereas the *src* protein is located on the plasma membrane[54].

None of the polyoma tumour antigens has been purified but there are suggestions that middle T, which is found in the plasma membrane, is at least associated with a kinase activity (W. Eckhart, Salk Institute; B. Schaffhausen, Harvard University; A. Smith, ICRF). This work relies on a kinase assay in which phosphate is transferred

from ATP to immunoglobulin or to middle T itself in immunoprecipitates of polyoma tumour antigens; it is thus impossible directly to implicate a virus-coded protein in the enzymatic reaction. However, kinase activity is detected in plasma membrane fractions, the location of middle T, and in transformed cell lines which lack large T but contain middle T. Moreover, there is no kinase activity in the cell line that contains the integrated DNA of an *hr-t* mutant and thus produces large T but not middle T. These results raise the possibility that middle T is a kinase, but they cannot rule out that the enzyme activity is a property of one of the other, less well characterised, viral proteins found in immunoprecipitates, or of a cellular protein that binds specifically to middle T.

In the immediate future we can expect the application of recombinant DNA techniques to lead to a detailed description of the integrated viral DNA found in transformed cells and of the mRNA species synthesised from it. In the longer term the central question to be addressed regarding the molecular biology of SV40 and polyoma will concern the enzymatic activities of the tumour antigens and the cellular targets on which these proteins act.

Ancient plate speeds

from Peter J. Smith

ABSOLUTE speeds of the Earth's lithospheric plates are generally lower for those plates having the greater proportions of continents, higher for those plates having the lengthier subducting edges, and higher for those plates with the greater colatitudes. But can these generalisations be regarded as universal rules holding over all time, or are they merely conclusions temporarily valid under current circumstances? Certainly the statistics are hardly impressive enough to inspire confidence in universality. It is true, for example, that all the plates having large continental components ($>2\times10^7$ km^2) have low speeds (< 30 mm a year); but there are only four of them, or not really enough to support the conclusion that large continents always move slowly. More generally, it would be rash to impute timelessness to any conclusion drawn from the behaviour of the mere 10–12 major plates in existence today.

On the other hand, investigation of past plate speeds is difficult. One approach would be to calculate absolute plate motions on the assumption that the Earth's hot spots are fixed with respect to the mantle; but it is not entirely clear that the assumption is valid, and ancient hot spot traces are difficult to recognise anyway. Solomon *et al.* (*J. geophys. Res.* **82**, 203; 1977) made rather more progress when they estimated plate motions during the early Tertiary on the assumption that there was no net torque between the lithosphere and mesosphere, concluding that generalisations derived from current plate behaviour were not always true in the past. But there is a limit on how far back in time this method can be applied, for it requires complete knowledge of ancient plate boundaries. It is also rather sensitive to the (usually unknown) amount of intraplate deformation which has occurred since.

In view of such difficulties, Gordon *et al.* (*J. geophys. Res.* **84**, 5480; 1979) have now devised a third method of estimating ancient plate motions — one based on palaeomagnetic data. The advantages of such a technique are that palaeomagnetic results for many continents cover at least several hundred million years and that it is possible in principle to determine apparent polar wandering paths with considerable accuracy. The most serious disadvantage, however, is that palaeomagnetism does not give the information necessary to specify continental motion in full. What Gordon and his colleagues have done is to devise a method whereby the data inherent in the polar wandering curve are converted into the rms velocity of the plate — a by no means simple procedure, for the precise relationship of apparent polar wandering to continental drift depends on the position of the continent with respect to the plate's pole of rotation. Because of the fundamental incompleteness of palaeomagnetic data, however, what emerges is not the actual rms velocity of a plate but a minimum rms velocity.

Obviously this is not ideal, but it turns out to be far from useless. Gordon *et al.* have applied their technique to the polar wandering curves for North America, Eurasia and Gondwanaland as specified by Irving (*Nature* **270**, 304; 1977) for the past 350 million years. The results clearly show that the relevant minimum rms continental velocities (V_m) have certainly not remained constant over that period. For North America V_m peaked about 190 million years ago at a value of more than twice the present one, and similar maxima occurred for Gondwanaland a few tens of millions of years earlier and for Eurasia slightly later. Indeed, the peak values of V_m were almost as great as the actual rms velocities of present oceanic plates. In each case the period of particularly rapid motion probably lasted 20–30 million years, which is more than sufficient to indicate that plates with large continents can move rapidly when circumstances permit.

In other words, both largely oceanic and largely continental plates are capable of moving rapidly (that is, at velocities greater than 60 mm a year) — which must mean that the resistance to motion of continental lithosphere cannot be substantially greater than that of oceanic lithosphere. The implication is that the present low velocities of continental plates arise from an accident of plate geometry. Gordon and his coworkers go on to speculate that the chief factor governing plate velocity is the proportion of plate boundary attached to subducting slabs. It just so happens that at present the largely continental plates are short on subduction zones; *ergo*, they are now moving only slowly.

Nevertheless, it may be quite wrong to conclude from all this that at any given time continental plates are just as likely to be travelling as fast as oceanic plates. Continental plates evidently can move as fast as oceanic plates, but the latter probably spend a higher proportion of their time actually moving rapidly than do the former. For although the motional resistances of the two types of plate may be comparable, the subduction cycles of the two may be quite different. Put very briefly, because continental and oceanic lithospheres behave rather differently when approaching and meeting trenches, subduction of an oceanic plate will continue for much longer than subduction of an otherwise comparable continental plate. The result, according to Gordon *et al.*, is that "Statistically . . . plate motions sampled at a given instant of time, such as the present, are likely to show a negative correlation between plate velocity and continental area." □

100 years ago

There is much more than the name of Cambridge to remind one of its namesake at home. Its quiet air of studious retirement, its quaint buildings and tree-shaded walks have much of the mother-country about them. One or two features of the place, however, are characteristically American. Thus in the great library at Gore Hall, most of the work of receiving and distributing books is done by young women, and done, too, with a noiseless decorum and celerity worthy of all praise. A magnificent Memorial Hall to those graduates of Harvard who fell in the late Civil War bears witness in its crowded lists of names that culture and courage may go hand in hand.

While Harvard is necessarily the great centre of scientific research, much admirable work is done in Boston in the way of practically expounding science. The Institute of Technology has for its primary object the education of the community in these branches of scientific knowledge conducive to progress in the arts and industries of life. In pursuance of this aim the methods of tuition are so practical and thorough that the results must be felt far beyond the industrial circles. Established mainly through the enlightened zeal of the present venerable President of the National Academy, Prof. W. B. Rogers, it began a few years ago to languish, but its founder has recently come back to its rescue, throwing himself into its affairs with all his old heartiness and kindliness until, freshened and stimulated by his influence, it is once more shooting up into lusty vigour.

D/H ratios in the unequilibrated chondrite Chainpur range up to 9×10^{-4}. Corresponding ^{17}O contents are 1‰ higher than in other LL chondrites, with varying ^{18}O contents. These results are discussed in terms of low temperature condensation of water and early irradiation by intermediate energy protons. The latter explanation is favoured.

THE determination of universal deuterium abundances is a major limiting factor on the density of the Universe and helps to determine a model for its expansion[1–3]. Several estimates of the D/H ratio in the protosolar nebula have been made on the basis of experimental data[4,5] and theoretical considerations[6,7]. Recent results give the average ratio as $1.9 \pm 1.1 \times 10^{-5}$ (ref. 8). Present theories on stellar evolution suggest that the thermonuclear reactions taking place at the centre of the Sun totally convert the deuterium into ^{3}He. Calculations show that the D/H ratio should be $\sim 10^{-17}$; direct measurements give a value of $< 2.5 \times 10^{-7}$ at the solar surface[9] and $< 3 \times 10^{-6}$ in solar wind[10]. Hence only planets and meteorites could have preserved some trace of deuterium cosmic abundance. Evolution of the primitive atmospheres on terrestrial planets has undoubtedly altered the initial abundance of deuterium during outgassing of the planet and preferential losses of light hydrogen in the upper atmosphere. On the Moon, present nuclear phenomena (implantation of solar wind protons, *in situ* production of spallation deuterium by galactic cosmic rays) are strong enough to blank out any trace of the primordial isotopic ratio.

In 1954, Boato[11] measured the D/H ratios in some type I and II carbonaceous chondrites. His work did not completely determine the amount of terrestrial pollution in these very fragile materials, which contain a large amount of partly exchangeable water. However, he observed a 40% variation of the D/H ratio and showed that some fractions of Orgueil and Mokoia contained hydrogen enriched up to 20% relative to SMOW, the upper range of deuterium enrichment (155.76 p.p.m.) for most terrestrial hydrogen components. Hence these fractions were probably traces of genuine extra-terrestrial D/H ratios. They show an approximately 10-fold enrichment relative to the primordial D/H estimate defined above. Little work was then done until, in 1975, we studied ordinary chondrites to ascertain whether this enrichment was an overall feature of telluric objects[12,13]. Our analytical procedure was much more sensitive than Boato's, allowing isotopic measurements on 0.1–20 mg samples. This makes it possible to test isotopic homogeneity on these samples, which are generally < 1 g.

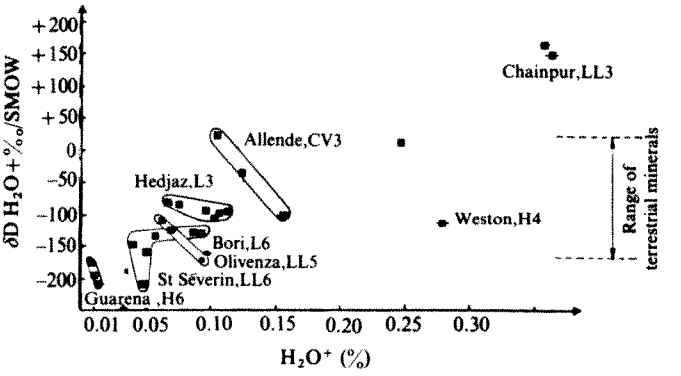

Fig. 1 D/H and hydrogen contents reported as H_2O^+ for various chondrites showing an overall positive correlation.

The results are summarised in Fig. 1, where D/H is plotted against H_2O^+ content (water extracted at $T > 200$ °C). They show a D/H variation from 124 p.p.m. for Guarena (LL6) to 220 p.p.m. for Chainpur whose conventional petrographic type is LL3 but whose matrix carbon content and chondrules' characteristics are very similar to those of carbonaceous chondrites. All these values are strongly enriched relative to the

0028-0836/79/510785—05$01.00

© 1979 Macmillan Journals Ltd

cosmic abundance (a factor between 6 and 11) and comparable to terrestrial values. On the other hand, we observe large variations between meteorites, and inside a single meteorite. These variations are particularly striking in the case of Chainpur. These features have been discussed[12-14] in the framework of accretion models of parent bodies and subsequent metamorphism of equilibrated chondrites. On the whole the results agree with the hypothesis of water adsorption on previously condensed grains, at temperatures varying from 180 to 230 K and total pressures of 10^{-2}–10^{-4} atmospheres, increasing with decreasing temperature, and of a corresponding increase of the D/H ratio due to a rapid increase of the fractionation coefficient $\alpha_{DH_2O-H_2}$ with decreasing temperature. Unequilibrated chondrites would completely retain these low temperature features whereas metamorphosed chondrites could have been depleted in water and deuterium by outgassing of variable quantities of deuterium enriched water (Fig. 2).

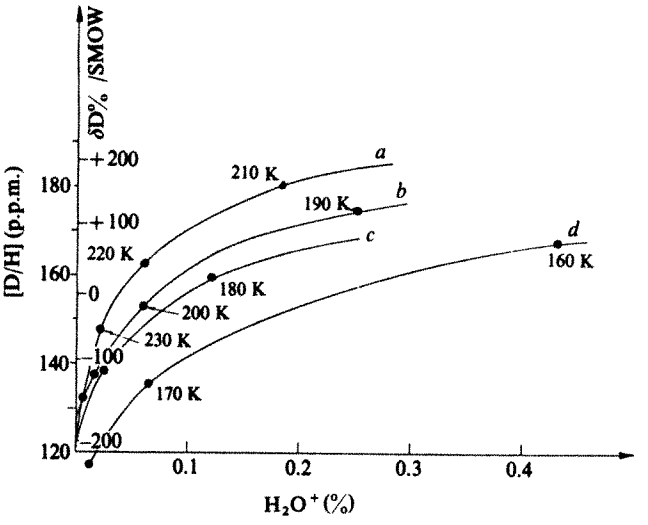

Fig. 2 Model of water adsorption on grains with fractionation H_2–H_2O_{sol} at various total pressures using data of Sill and Wilkening for total water adsorption and Richet *et al.* for $\alpha_{D\,H_2-H_2O_{sol}}$. Curves: *a* $P_T = 10^{-2}$ atm, $(D/H)_{H_2} = 25$ p.p.m.; *b*, $P_T = 10^{-3}$ atm, $(D/H)_{H_2} = 19$ p.p.m.; *c*, $P_T = 10^{-4}$ atm, $(D/H)_{H_2} = 15$ p.p.m.; *d*, $P_T = 10^{-5}$ atm, $(D/H)_{H_2} = 11$ p.p.m.

This model, while satisfactory for the whole meteorite sample, implied drastic temperature and pressure variations to explain the total range (140–218 p.p.m.) observed in a 1-g sample of Chainpur. We therefore decided to measure ^{18}O and ^{17}O abundances on the same samples, to look for possible relationships between deuterium contents and the location of these samples in a $\delta^{17}O$–$\delta^{18}O$ diagram[15]. (δD, $\delta^{17}O$ and $\delta^{18}O$ are defined as: $\delta = (R_{Sample}/R_{SMOW} - 1) \times 1{,}000$, where $R = D/H$, $^{17}O/^{16}O$, $^{18}O/^{16}O$.)

Analytical procedure

Analyses have been made on five samples (chondrules and matrix) separated by gentle crushing. The chondrules were then picked up and washed from matrix debris with acetone in an ultrasonic tank. The Chainpur matrix originally contained debris of chondrules[16] so that the 'matrix' sample is only the most enriched in matrix material in a petrological sense. Hydrogen was extracted by heating with an electrical resistance furnace.

Our previous results[12-14] were obtained by a vacuum extraction technique. For the present study, the extracted gases were carried by an helium flow through a vanadium furnace heated at 800 °C where the reduction of the hydrogen compounds takes place, and then introduced directly into the ion source of the mass spectrometer after selective diffusion of hydrogen through palladium heated at 450 °C. The gas mixture flows along a tube made of silver–palladium alloy (50 mm long and 0.08 mm thick) which is directly sealed to the line of the mass spectrometer. The flow of helium (~ 0.25 cm^3 s^{-1}) is kept small relative to the diffusion rate of hydrogen through the silver–palladium tube (~ 1 cm^3 s^{-1}). Thus the variation of the isotopic composition of hydrogen with rising temperature is continuously monitored.

Systematic calibrations are made to measure the absolute sensitivity of the whole apparatus to hydrogen and D/H ratios, using known amounts of hydrogen with a known D/H ratio. The method has been checked by the analysis of a terrestrial phengite provided by O'Neil with $\delta D = -39‰$. Three measurements of this sample gave $-40 \pm 2‰$ with a flat stepwise heating D/H release pattern between 200 and 1,200 °C.

After hydrogen extraction, oxygen was recovered by the BrF_5 technique, purified through a 5 Å molecular sieve, collected and analysed as O_2 in Micromass 602C double collecting mass spectrometer. We checked that no impurities were present, which could contribute to masses 33 or 34 (essentially NF_3 which would appear also at mass 52 (ref. 17)). Traces of CF_4 were occasionally present, which could not modify the 33 or 34 currents.

Table 1 shows the results as conventional H_2O^- (hydrogen extracted below 200 °C) and H_2O^+ (>200 °C) contents. For samples *A* and *B*, H_2O^+ has been extracted by heating between 200 and 1,150 °C at a rate of about 15 °C min^{-1}. For samples *C*, *D* and *E* temperature steps have been observed. Table 1 and Fig. 3 show that deuterium rich fraction 3 is extracted between 450 and 750 °C. The relatively high values of the D/H ratio observed in the hydrogen extracted at $T > 750$ °C may, at least partly, reflect a tailing effect of the whole extraction line, mainly in the vanadium furnace and the palladium membrane. In contrast, it is worth noting that: (1) that fraction 2 ($200 < T < 450$ °C) is not enriched in deuterium compared with fraction 1

Table 1 Oxygen and hydrogen isotope composition of Chainpur samples

Samples	H_2O (10^{-4} g per g)	D/H (p.p.m.)	$\delta^{17}O‰$ (SMOW)	$\delta^{18}O‰$ (SMOW)

Oxygen data refer to whole sample after hydrogen extraction by step heating experiments.

(H_2O^-); and (2) that no correlation is observed between the isotopic ratios of fractions 2 and 3 (Fig. 3).

The values of D/H measured in fraction 3 of samples *D* and *E* are the highest ever recorded in natural samples. D/H ratios up to 300 p.p.m. have been measured[18] in a lunar rock irradiated by cosmic rays, where the high values of D/H were observed in fractions extracted at $T < 470$ °C in a back ground of normal, deuterium free, lunar hydrogen of solar-wind origin.

The $\delta^{17}O/\delta^{18}O$ ratio (Table 1 and Fig. 4) diagram[15] enables a distinction to be made between physicochemical (mass dependent) fractionations, which correspond to variations along a straight line of gradient $\frac{1}{2}$ and nuclear effects which define other correlations or possibly no correlation at all.

Chainpur results are variable, and, except for sample *A* plot well above the mean value for LL chondrites measured by Clayton *et al.*[17] defining approximately a straight line of gradient $\frac{1}{2}$ translated by +0.5‰ in $\delta^{17}O$ relative to the LL straight line. Hence Chainpur samples contain more ^{17}O than any other object in the Solar System or less pure-^{16}O component. This is related to the fact that Chainpur is the only LL3 analysed to date and work in progress suggests that even larger oxygen isotope heterogeneities exist in this meteorite and other type 3 chondrites.

Discussion

There are two main explanations for such results, one relating to physicochemical fractionations and one to nuclear effects and they will probably have to be mixed to some extent.

The driving mechanisms are: temperature variations for the physicochemical fractionation, mixing with presolar grains or heavy energetic irradiations for nuclear effects (oxygen, magnesium, neon, and so on).

Until the discovery of the $^{17}O/^{18}O$ anomalies in the meteorite Allende[16] oxygen isotope variations in meteorites had been mainly explained in terms of physicochemical fractionations. The few D/H results, since deuterium formation is attributed almost exclusively to the big bang[1,2], have also been explained by physicochemical fractionations[19] eventually associated with mixing to deuterium free solar wind[10]. The departure from physicochemical effects can be demonstrated if more than two isotopes are present (oxygen) and is much more difficult for elements such as hydrogen which have only two stable isotopes. The main indication for an isotope anomaly in these elements would be the size of the isotopic effect and an eventual correlation with other definitely nuclear effects.

Although irradiation models have recently been considered for oxygen[20–22], the variations are so large and most of them so well correlated on a $\delta^{17}O/\delta^{18}O$ diagram[15,17] that the hypothesis of presolar grains resulting from the explosion of a nearby super nova[15] and carrying pure ^{16}O, is still more convincing. Chainpur would be the least contaminated by this pure ^{16}O component. Isotopic variations among samples *C*, *D* and *E* could be attributed mainly to physicochemical fractionations whereas sample *A* would reflect a different proportion of ^{16}O component. Alternatively this departure from the straight line with gradient 1/2 could be due to ^{17}O and ^{18}O created from spallation reactions.

Temperature dependent fractionation

The step heating process reveals for hydrogen, inside a given fraction, large heterogeneities with enormous D/H ratios. To account for these ratios in the framework of water adsorption at low temperatures, we have to consider temperatures down to 110 K. In a simple black-body model this corresponds to a distance of about 3 AU, the location of the asteroid belt, but this cannot be used as a definitive argument since Wetherill[23] demonstrated that the asteroid belt is a kind of gravitational well for small objects coming from a large region of the Solar System. Measurement on interstellar clouds from the Orion nebula[25] shows an enormous D/H ratio in the HCN molecule, more or less correlated with the temperature down to 10 K, which could be obtained by equilibrium or kinetic, temperature dependent, fractionations.

Hence the observed D/H distribution in Chainpur may be the result of a very complex mixing of hydrogen compounds condensed at various temperatures in the solar nebula or even remnants of the interstellar medium. However, the fact that D/H fractionations in Orion depend on the temperature down to 10 K indirectly suggests that any change to a higher temperature would redistribute the D/H ratios. In particular in chondrules, which were strongly heated and probably fused, we should have uniform D/H ratios. This, together with the medium temperature range (450–750 °C) at which we obtain the D/H peak is against the survival of volatile molecules and in support of the creation of anomalies after the chondrules formation.

Early irradiation model

Deuterium can be created in various environments. Besides the big bang which is the most favoured model, two hypotheses directly relate to the early history of the Solar System. The first one is the effect of shock waves in supernovae envelopes[27]. The conditions postulated for the production of deuterium in such envelopes are far different from those considered for the production of the isotopically anomalous presolar grains and require energies $>10^{53}$ erg, which have not been observed. Also our deuterium enrichments have been found in the ^{17}O and ^{18}O

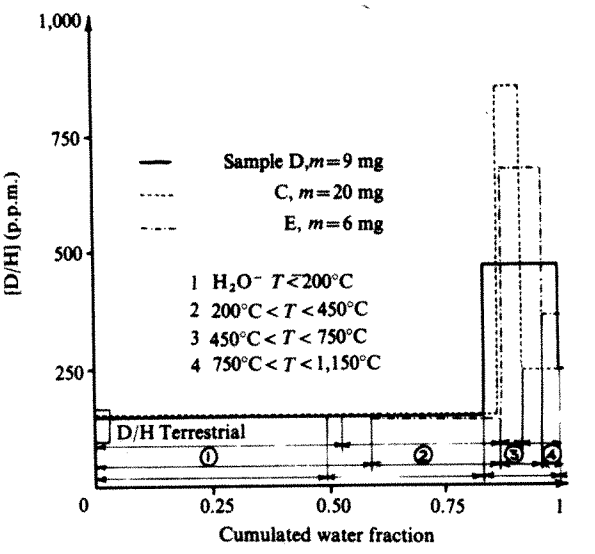

Fig. 3 D/H and water contents extracted during stepwise heating experiments of Chainpur samples, corresponding to the data of Table 1.

richest material which is exactly the opposite of what is expected of presolar grains originated from supernovae. The second involves an early irradiation within the Solar System. This hypothesis is rejected by Reeves *et al.*[2] and seriously questioned by Epstein *et al.*[26] for deuterium production, it also has been considered to explain neon, oxygen, magnesium and other isotope anomalies discovered in the 1970s. It is finally rejected by Clayton *et al.*[21] and proposed with special and somewhat *ad hoc* limitations by Lee[22]. However, our very special deuterium anomaly leads us to reconsider it.

If this model proves to be reasonable, we shall also have to consider its logical extension: not only the D/H ratio is heterogeneous in Chainpur but every chemical and petrological feature and this is due to the fact that it is an unequilibrated

chondrite. If the early irradiation affected Chainpur, it possibly also affected the parent material of larger objects such as the Earth where the deuterium was largely redistributed and homogenised. Hence this irradiation can be responsible for the production of a large proportion of the deuterium on Earth and other large objects even if the original signature has been lost by homogenisation. If energetic and cosmochemical evidence is not violated this hypothesis cannot be ruled out.

In such a model first we have to estimate which part of the deuterium measured on our experiments is the spallation product: that corresponding to the peak of very high D/H, the deuterium excess relative to the equilibrium content relative to the nebula at a given temperature, or the whole deuterium content. Given the importance of the high D/H peak, the three possible choices give results comparable within an order of magnitude. For simplicity, we have reported in Table 2 the deuterium quantities corresponding to H_2O^+ (hydrogen extracted at $T > 200$ °C).

We also have to decide what is the possible contribution of terrestrial contamination: for all our experiments on chondrites[12,13], it has been considered negligible above 200 °C.

Several spallation reactions by protons produce deuterium with reasonable yields. For a power law energy spectrum ($d\phi/dE = Ke^{-\gamma}$ with $2 < \gamma < 5$) and low energy cutoffs of <10 Mev, these reactions typically have effective cross-sections of the order of 0.1 b (ref. 21). The most efficient should be on oxygen and iron targets in the solid state and helium in the gaseous state. We cannot get such high D/H in the gas without unreasonably high fluences. In the solid, due to the high (Fe + O)/H ratio, necessary fluences are much lower. They are listed in Table 2 where they range from 10 to 10^{20} cm^{-2}. These fluences could be notably reduced (down to a factor of 10) if capture of secondary neutrons produced by spallation were also considered[3]. However, for this process to be really efficient, we need thermalised neutron fluences up to 10^{20} cm^{-2} which should show up on the isotopic composition of elements such as gadolinium, which should be looked for in Chainpur. Until then we shall assume that the necessary proton fluence is 10^{19}–10^{20} cm^{-2} which is comparable to that considered by Clayton *et al.*[21] to produce the ^{26}Mg anomaly in Allende but much less than the fluence needed to produce the maximum oxygen anomaly (10^{23}–10^{25} cm^{-2} according to the scenario[21,22]).

Energy limitations

The next step is to decide what kind of system and what global mass was irradiated by such an effect. If the spallation deuterium is restricted to the peak and not found in other objects, this means that the irradiation is restricted to the surface of tiny objects like Chainpur parent body and the energy problem will not be too serious. The isotopic and chemical difficulties are reviewed later. However, this is an *ad hoc* scenario and this proton fluence is more likely to come from the main source of energy of the system which is the young Sun. Then all the matter exposed between the Sun and the location of Chainpur condensation (and possibly further) has to be considered. The period which we must consider is that during which solids condensate, planetary bodies accrete and residual nebula is swept away, and it might be very short (10^7–10^8 yr). The period of T Tauri radiation itself might be much shorter (10^6 yr)[29]. Possible scenarios, such as nuclear and energy needs, strongly depend on when precisely the T Tauri phase occurs in the longer period: if a planet is already formed then the effects of the radiation will be only surficial and vanish eventually by mixing. This is particularly important for the jovian planets. If the nebula has already been swept away, then the stopping distance is much larger, the mass involved and the energy needed considerably reduced. The careful examination of deuterium contents may then set the average accretion time of planets relative to the T Tauri phase and to each other.

Practically, if we want to apply a 10^{20} cm^{-2} fluence to the jovian planets or to a nebula of 10^{-5}–10^{-3} atmospheres total pressure extending over ~1 AU, we have to consider a total mass of 10^{-3}–$2 \times 10^{-1}\ M_\odot$, which leads to totally unreasonable energy dissipation.

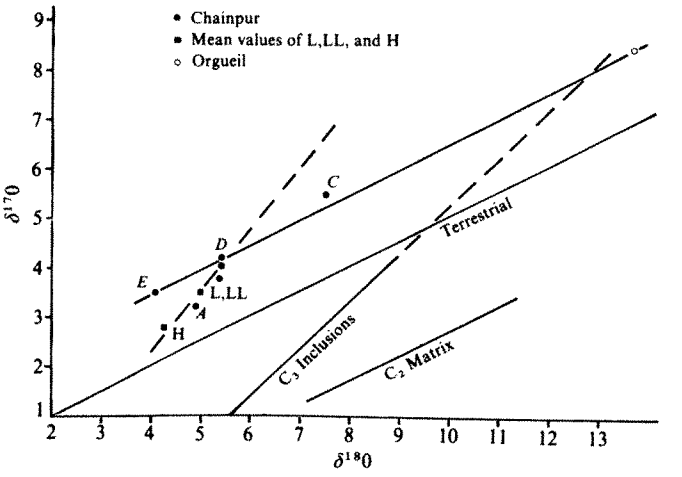

Fig. 4 $\delta^{17}O/\delta^{18}O$ plot of the isotopic composition of Chainpur samples, corresponding to the data of Table 1. ■, data from ref. 21.

In contrast, the hypothesis which suggests that the deuterium content of the terrestrial planets could largely be due to spallation is reasonable from an energetical point of view. The global D/H ratios in meteorites and the Earth vary from 140 to 220 p.p.m. and are thus very similar. The Earth probably contains most of the total deuterium estimated at 1.5×10^{43}–1×10^{44} atoms. This number cannot be more than doubled if we take into account all the terrestrial planets. If this whole mass was irradiated in its dust form to produce most of its deuterium, we can calculate the total energy needed, mostly lost by ionisation. The total mass corresponds roughly to 5×10^{50} atoms. Taking a mean ionisation cross-section of 10^{-26} erg cm^{-2} as an upper limit and making calculations similar to Lee's[22], we find a total energy of 5×10^{44} erg (of which 5×10^{39} erg only are dissipated by the formation of deuterium). This is roughly 10^{-4} of the total gravitational energy of the Sun. The only remaining problem is the question of the stopping distance; which strongly depends on the particle energy. For example, the residual trajectory is 5–15 10^{-2} g cm^{-2} for a 10 MeV proton and 55–130 g cm^{-2} for a 500 MeV proton in hydrogen and oxygen respectively[30,31]. For a 500 MeV proton, the energy dissipated by nuclear reactions would increase to 2.5×10^{41} erg but the total energy loss would eventually decrease because the stopping power is less. The total flux of such protons ($\phi \times t = 10^{20}$ cm^{-2}) across a sphere of 1.5 AU radius would amount to 2×10^{44} erg, roughly one-third of the total energy need. Whether this intermediate range of energy, postulated by

Table 2 Total deuterium contents (atoms per g), corresponding to H_2O^+ (extracted above 200 °C) and corresponding fluences needed for protons of $E > 10$ MV

Sample	D in H_2O^+ (atoms per g)	$I \times t$ (protons cm^2 s^{-1})
A	12×10^{15}	3.3×10^{19}
B	8.1×10^{15}	2.2×10^{19}
C	7.1×10^{15}	2.0×10^{19}
D	7.0×10^{15}	1.9×10^{19}
E	30.2×10^{15}	8.4×10^{19}

Fowler *et al.*[2] is realistic is debatable but it is energetically reasonable. It provides much longer travel distances, which would allow the protons to penetrate deeply (~40 cm) into planetesimals, and not only dust, and also to travel 1 AU into a 3×10 g cm^{-3} (3×10^{-8} atm) nebula.

Cosmochemical constraints

The total amount of deuterium formed is only 3×10^{-8} of the estimated protosolar deuterium. Hence the global deuterium cosmology is not strongly modified inasmuch as only 7–30% of the matter is supposedly reprocessed in stellar systems. But the early irradiation can have very strong effects on other elements in the irradiated materials, especially on Li, Be, B, rare gases, magnesium (^{26}Mg) and also on rarer nuclei such as ^{50}V, ^{92}Nb, ^{138}La, ^{180}Ta (refs 21, 22). As most of the latter nuclei still have to be investigated, we only consider the problem of light elements and mention the rare gases limitations.

We stress that our deuterium anomaly does not apply to the same type of material as Allende's inclusions (as is reflected by the mineralogy and also by the ^{17}O ^{18}O results), but the postulated fluences are similar to that proposed by Clayton *et al.*[21]. They would produce rather significant amounts of Li, Be and B by spallation on oxygen, carbon and nitrogen[32] and also large amounts of rare gases among which the already discussed ^{22}Ne, and ^{36}Ar and ^{38}Ar from ^{39}K and ^{41}K respectively[21]. They could also produce ^{17}O and ^{18}O by spallation on the Si group, with rather small cross-sections (~10 mb), but, because of the large abundance of the Si group about 10 times more efficient than the destruction reactions.

These spallations (mainly on Si and Mg), could produce 10^{15}–10^{16} atoms g^{-1} of ^{17}O and ^{18}O which corresponds to variations in δ^{17}O of 0.15 to 1.5‰ and in δ^{18}O of 0.03 to 0.3‰. The ^{17}O variations approximately match the total offset relative to a straight line with a gradient of $\frac{1}{2}$ whereas the ^{18}O variations are much smaller than the observed values. This can reflect the result of two different processes: (1) the proton irradiation, acting mainly on ^{17}O and (2) the effect of mass dependent fractionations, occurring, for example, during the formation of the chondrules, which would bring the isotopic composition of the condensed phases from δ^{18}O ~ 4‰ closer to the nebular composition (+13 to +14‰ after the intercept between Chainpur line and Allende's inclusions line).

Consider then the Li, Be and B: using cross-sections of 10–20 mb (ref. 29), we calculate for our maximum influence of 10^{20} cm^{-2} a production of about 0.3 p.p.m. of Li and about twice as much B. The production of Be should approach 0.01 p.p.m. If we compare this to the observed concentrations[33–35] which range from 1 to 3 p.p.m. for Li and B, we have to account for a 10–60% increase, which from an elemental point of view is perfectly acceptable.

The most severe limitations come from the isotopic composition as there are large differences between meteoritic and spallation-produced ^{7}Li/^{6}Li. Observed meteoritic ^{7}Li/^{6}Li are up to now equal within a few per cent to 12.5 including Chainpur[33] whereas spallation Li has ^{7}Li/^{6}Li ranging from ~3 to 7 depending on the energy range. The data of Chainpur show that we should expect a decrease of ^{7}Li/^{6}Li from 12.7 to 12 or 11.4, which should be perfectly measurable.

Now our model attempts to explain essentially all the observed D/H ratios in terrestrial objects and for them we need comparable fluences. For the Sun and stars we have only a lower limit for ^{7}Li/^{6}Li and the only accurate numbers are for terrestrial objects, so the observed homogeneity may be the result of mixing in almost constant proportions of lithium from three sources: ^{7}Li from the big bang, ^{7}Li and ^{6}Li from galactic cosmic radiation, producing only a few per cent variation. Note that this remarkable homogeneity remains to be satisfactorily explained even if we remove the third component.

The postulated fluences produce too much ^{22}Ne in the solid as discussed by Clayton *et al.* For Chainpur (0.1% K) the ^{36}Ar production should be $0.5\text{–}5\times10^{-6}$ cm^3 STP g^{-1}, which satisfactorily matches the results obtained by Podosek[36] (0.85 to $>1.18\ 10^{-6}$ cm^3 STP g^{-1}). The ^{36}Ar/^{38}Ar spallation ratio should vary between 15 and 70 according to the energy spectrum[21]. The ratio observed by Podosek is 3.5–4.0 in an irradiated sample. If ^{38}Ar is corrected for ^{38}Ar produced from ^{37}Cl (^{37}Cl(n, γ, β)^{38}Ar) as for Karoonda[36,37], the ratio is 10–14, very different from the solar value. However, other results on Chainpur[38] do not confirm this result. Also, the mechanisms by which the Earth can rebuild a solar ^{36}Ar/^{38}Ar after the early irradiation remain to be imagined precisely.

Conclusion

In the meteorite Chainpur we have found very large anomalies in deuterium contents associated with small enrichments in ^{17}O and larger variations along a straight line with gradient 1/2 in a δ^{17}O/δ^{18}O diagram. Deuterium results can be explained by a temperature dependent model of fractionation in a wide range of low temperatures, but an early irradiation during the T Tauri phase is presently favoured, which could explain most of the hydrogen and oxygen isotope features. The extension to C_1 chondrites is very difficult because the deuterium amounts are 20 times larger.

We thank P. Pellas for samples. J. Audouze for his kindness, and J.-F. Minster, C.-J. Allegre and E. Roth for helpful comments.

Note added in proof: Since this report was written Clayton and Mayeda found very similar results to the Chainpur samples on a LL3 chondrite recovered from Antarctica (ANS) (see ref. 40).

Nebular condensation of Ga, Ge and Sb and the chemical classification of iron meteorites

Chien M. Wai
Department of Chemistry, University of Idaho, Moscow, Idaho 83843

John T. Wasson*
Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California 90024

Key parameters for classifying iron meteorites into genetic groups are concentrations of Ga and Ge. Their taxonomic value results from the combination of very wide concentration ranges in iron meteorites as a whole, with very narrow concentration ranges in most individual groups. The very wide intergroup ranges result from solar nebular condensation in widely varying conditions. Recent calculations show that the nebular condensation temperature of Ge is lower than that of any other siderophile, and that Sb and Ga are the next most volatile siderophiles. The narrow intragroup ranges of Ga and Ge reflect minimal fractionation during the crystallisation of cores, larger intragroup ranges for Sb result from a solid/liquid distribution ratio near 0.4.

Only during the past 20 yr have meteorite researchers developed a genetic classification for iron meteorites[1-5]. This system, often called the chemical classification, is based on a combination of metallic structure and the concentration in the metal of several siderophile (metal-preferring) elements, most especially Ga and Ge[6-8]. The Ga–Ni and Ge–Ni fields occupied by the 13 groups of iron meteorites are shown in Fig. 1. Although the total concentration ranges among all meteorites are 1,600 and 400,000 for Ga and Ge, respectively, only the two groups IAB and IIICD have maximum/minimum ranges >2. There is evidence which indicates that the groups having wider ranges were never fully molten; their large Ga and Ge ranges may have been established during nebular fractionation[9,10] or partial melting processes[11]. Most evidence favours the view that the remaining 11 groups formed in planetary cores that were once fully molten[12,13].

The explanation for the Ga–Ge quantisation has been sought for the past two decades. Anders[14,15] and Scott[12] attributed the large concentration ranges to nebular volatility, but were not able to explain why other siderophilic elements that appeared to be equally or more volatile did not exhibit similar distributions. Wai *et al.*[16] examined the possibility that the low Ge contents could have resulted from preferred partitioning into silicate (mantle) materials; their experiments showed that Ge was highly siderophile in temperature and redox conditions appropriate to core formation.

Non-nebular fractionations have produced large intragroup concentration range of some elements (such as, Ir, Os and Re ranges of a factor 5,000 are observed in group IIAB), requiring extreme care when estimating group means. To calculate intergroup ranges we have reviewed published data[17,18] and used treatments involving fractional crystallisation equations or weighting to achieve precise mean compositions[19], then calculated mean abundances relative to Ni. The six highest maximum/minimum abundance ranges are 15,400, 890, 138, 55, 36 and 11.4 for the elements Ge, Ga, Sb, As, Cu, and Au, respectively. We have previously calculated 50% condensation temperatures for several moderately volatile elements and showed that there was an approximately monotonic decrease in the ordinary-chondrite/CI-chondrite abundance ratio with decreasing nebular condensation temperature[20]. As expected, the maximum/minimum abundance ranges in iron meteorites are also negatively correlated with our previously published condensation temperatures, but an important exception is that the Ga range is higher than that of Sb despite the fact that our previously calculated Ga condensation temperature was 150 K higher than that for Sb.

Nebular equilibria

The correctness of equilibrium condensation calculations depends largely on the quality and completeness of available thermodynamic data of the relevant gaseous and condensed forms of the element under consideration. For example, if lack of data results in exclusion of a stable gaseous form of an element from the calculation, the calculated condensation temperature will be too high. If a minor or trace element condenses in solid solution with a major mineral phase, calculation of a correct condensation temperature requires inclusion of an appropriate activity coefficient (γ) of the element in the host phase. In most previously reported condensation temperatures γ was taken equal to unity, that is, ideal solution behaviour was assumed. In our published calculations[20] we estimated γ values that were assumed to be independent of temperature.

In fact, the activity coefficient depends both on temperature and composition. The relationship of γ to the temperature T, the partial molar heat of solution $\Delta\bar{H}_s$ and the excess partial molar entropy of mixing $\Delta\bar{S}^{xs}$ is given in standard thermodynamics texts[21]:

$$\ln\gamma = \frac{\Delta\bar{H}_s}{RT} - \frac{\Delta\bar{S}^{xs}}{R} \quad (1)$$

where R is the gas constant. Based on available data, we have estimated the activity coefficients of the six most volatile siderophilic trace elements in Fe–Ni according to equation (1). The partial molar quantities for each trace element given in Table 1 are for a dilute solid solution with the mole fraction (X) of the element approaching zero; the Fe:Ni mole ratio is assumed to be 12. The quality and suitability of the available thermodynamic data vary, as described below.

The activity coefficient of Au in Ni (γAu[Ni]) at 1,150 K approaches 10 as X_{Au} approaches zero[22]. At 1,123 K γAu[Fe] data are available only for X_{Au} from 1.0 to 0.45; the trend follows closely that of γAu[Ni]. Therefore, the $\Delta\bar{H}_s$ and $\Delta\bar{S}^{xs}$ for Au in Fe–Ni were assumed to be identical with those for the Au–Ni system. Activity coefficients of Cu in solid Ni or Fe are not available, but γCu[Ni] and γCu[Fe] at $X_{Cu} = 0$ have been reported for liquid systems at 1,823 K (ref. 22). Solid phase γ

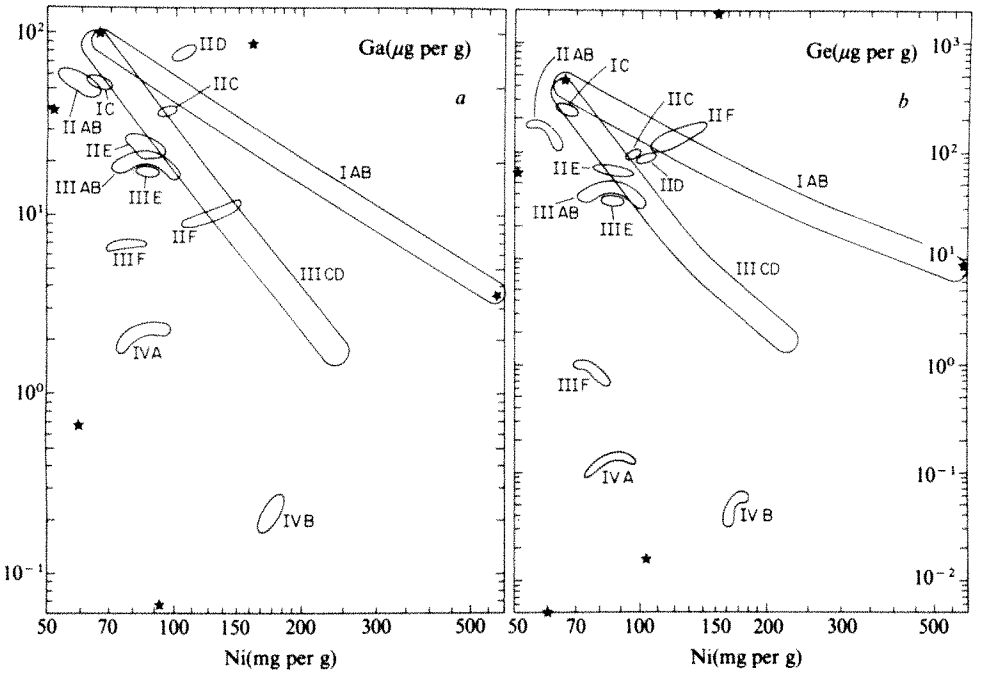

Fig. 1 log–log Ga–Ni (*a*) and Ge–Ni (*b*) diagrams; note differences in the logarithmic scales. The large concentration ranges in the non-magmatic groups IAB and IIICD reflect the fact that they were not subjected to the homogenisation associated with core formation. The 11 groups that formed on cores show quantised Ga and Ge ranges (factors ≤1.7) and minimal overlap. Stars show the locations of the iron having maximum and minimum concentrations of these three elements; two are members of group IAB and the remainder ungrouped.

values were calculated based on iron meteoritic evidence that the equilibrium partition coefficient of Cu between liquid and solid Fe–Ni is close to unity, that is, the γ value of Cu in solid Fe–Ni should be close to that for liquid Fe–Ni (ref. 19). From these data we estimated the Cu[Fe–Ni] partial molar quantities.

We estimated partial molar quantities for Ge in Fe–Ni from infinite dilution γGe[Fe] and γGe[Ni] values at 1,800 K (refs 23, 24), and from a solid/liquid distribution coefficient of 0.89 observed in low-Ni group IIIAB iron meteorites[19]. Extrapolation below $X_{As} = 0.11$ yielded γAs[Fe] = 0.5 at infinite dilution at 1,573 K (ref. 25). We estimated the partial molar quantities for As in solid Fe–Ni from these data and from the As solid/liquid distribution coefficient of ~0.41 inferred for group IIIAB (ref. 19). Partial molar quantities for these four siderophiles are based on high-temperature experimental data from dilute binary solutions and from meteoritic measurements. A major source of uncertainty in this application is the assumption that $\Delta\bar{H}_s$ is temperature independent over a wide temperature range. An error of 1–2 kcal mol^{-1} in the estimated $\Delta\bar{H}$ values would change the 50% condensation temperatures by 10–30°. Our estimated uncertainties are of this order.

The enthalpies of formation in solid Ga–Fe and Ga–Ni systems have been reported to exhibit large negative deviations with maximum values of −8.5 kcal mol^{-1} (ref. 26) and −11.5 kcal mol^{-1} (ref. 27), respectively. Hultgren *et al.*[22] give a γGa[Ni] at 1,223 K of 3.3×10^{-3} at $X_{Ga} = 0.37$. Kelly and Larimer[11] suggested a lower γGa[Fe–Ni] of 3×10^{-3} which we find more in keeping with the lower $\Delta\bar{H}_s$ data for Ga–Fe, and our partial molar quantities were chosen accordingly.

Like its congener As, Sb forms stable compounds with Fe and Ni (ref. 21). The integral heat of solution and excess entropy of mixing of Sb in solid Fe at 800 K and $X_{Sb} = 0.45$ are −2.3 kcal mol^{-1} and −2 cal deg^{-1} mol^{-1}, respectively[22] and γ is 0.23 at $X_{Sb} = 0.3$ at 893 K (ref. 28). However, data for dilute Sb–Fe or Sb–Ni solid solutions are not available. Takahashi *et al.*[29] used $\gamma = 1 \times 10^{-3}$. This γ value at a typical Sb condensation temperature of ~900 K corresponds to a $\Delta\bar{H}_s$ of −14 kcal mol^{-1} if $\Delta\bar{S}^{xs}$ is −2 cal deg^{-1} mol^{-1}. This $\Delta\bar{H}_s$ is implausibly more negative than that estimated for As in Fe–Ni, thus we chose a smaller $\Delta\bar{H}_s$ value. The partial molar quantities of Sb given in Table 1 are more in keeping with the expectation that, given their closely similar electronic configurations, γ for Sb (radius ~1.6 Å) should be somewhat larger than that for As (radius ~1.5 Å) since As fits better into Fe–Ni lattice sites (mean radius ~1.28 Å)[30].

Because of the paucity of data, the relative uncertainties in the estimated partial molar quantities for Ga and Sb are ~±30%. The errors in our calculated condensation temperatures for Ga and Sb caused by uncertainty in their activity coefficients are probably twice as large as those for Au, Cu, As and Ge. Despite the uncertainties in their activity coefficients we believe our calculated condensation temperatures for these elements are the most accurate allowed by currently available data.

We need to revise our previous results[20] regarding the distribution of Ga, Ge, and Sb among nebular gaseous species. Recently published data on GaOH(g)[31] show it to be an important species, and Sears[32] showed that GaCl(g) is also important. The nebular condensation of Cl is poorly understood, but it is more depleted than Ga in ordinary chondrites[33,34], suggesting that its condensation temperature is lower. Although the low abundance of Br limits its importance, GaBr(g) is also a stable nebular species[35]. Based on the assumption that Cl condensed after Ga, we evaluate the relative abundances of Ga(g), GaOH(g), GaCl(g) and GaBr(g) from the

Table 1 Equilibrium nebular 50% condensation temperatures of some moderately volatile siderophilic elements

Element	Gaseous form	Condensed form (host)	Solution data $\Delta\bar{H}_s$	Solution data $\Delta\bar{S}^{xs}$	Condensation temperatures (K) 10^{-4} atm	Condensation temperatures (K) 10^{-6} atm
Au	Au(g)	Au (Fe–Ni)	6.0	1.5	1,225	1,074
As	As(g)	As (Fe–Ni)	−9.5	−2.5	1,157	1,012
Cu	Cu(g)	Cu (Fe–Ni)	11.0	2.0	1,037	910
Sb	SbS(g)	Sb (Fe–Ni)	−7.0	−2.0	912	767
Ga	GaCl(g)	Ga (Fe–Ni)	−9.0	−2.5	918	738
Ge	GeS(g)	Ge (Fe–Ni)	−16.0	−3.6	825	702

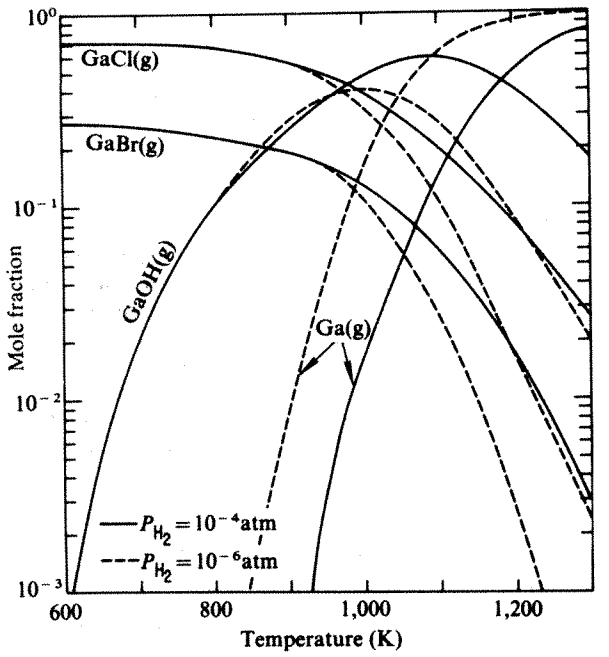

Fig. 2 Distribution of Ga among gaseous species in the solar nebula at pressures (P_{H_2}) of 10^{-4} and 10^{-6} atm. At high temperatures Ga is dominant, but with decreasing temperature first GaOH then GaCl become the most abundant gaseous forms.

following equilibrium processes:

$$GaOH(g) + 1/2H_2(g) = Ga(g) + H_2O(g)$$

$$GaOH(g) + HCl(g) = GaCl(g) + H_2O(g)$$

$$GaCl(g) + HBr(g) = GaBr(g) + HCl(g)$$

The solar abundance of Cl (4,350, Si = 10^6) using in this calculation was taken from the Dreibus *et al.*[34] data or CI chondrites; the Br abundance (9.7, Si = 10^6) is based on unpublished data of B. Spettel, H. Wänke and G. W. Kallemeyn. The remaining abundances are from Cameron[36]. The relative abundances of these four Ga species in the temperature range 600–1,200 K at nebular pressures (P_{H_2}) of 10^{-4} and 10^{-6} atm are shown in Fig. 2. The abundances of GaO(g) and $Ga_2O(g)$ are insignificant in this temperature range. The condensation of Ga was calculated from:

$$GaCl(g) + 1/2H_2(g) = Ga(s, \text{in Fe–Ni}) + HCl(g)$$

with the mole fraction of GaCl(g) corrected using the calculated distribution curve shown in Fig. 2.

The abundance of GeS(s) was underestimated in our previous study[20]; we concur with Sears[32] that it is the most abundant gaseous species of Ge. The condensation of Ge was calculated from available thermodynamic data[37,38] by the following equilibrium process:

$$GeS(g) + H_2(g) = Ge(s, \text{in Fe–Ni}) + H_2S(g)$$

The partial pressures of GeS(g) used in our calculation were corrected for the minor amounts of GeSe(g) and GeTe(g) in the nebula[39].

Our[20] Sb condensation calculations are in need of revision to allow for the fact that SbS(g) is more abundant than Sb(g) at temperatures below 1,150 K. The condensation of Sb was recalculated from free-energy functions[39] and $\Delta\bar{H}_f^0$ (298 K)[40] data:

$$SbS(g) + H_2(g) = Sb(s, \text{in Fe–Ni}) + H_2S(g)$$

The condensation processes for the other three siderophiles Au, Cu, and As as discussed previously[20] seem to be correct, but condensation temperatures have been recalculated to include the temperature dependent γ values.

The revised 50% condensation temperatures for Au, As, Cu, Sb, Ga, and Ge at nebular pressures of 10^{-4} and 10^{-6} atm are given in Table 1. As in our previous study, Ge is the most volatile siderophile. The revised Ga 50% condensation temperature is now similar to, or slightly lower than, that of Sb; thus these two elements are the next most volatile elements siderophilic at temperature and redox conditions appropriate to core formation. Our condensation calculations support the idea that the extremely large range in mean group abundances for these elements are a direct reflection of their high volatility in the nebula. In groups having low abundances they seem to have been lost to a large degree during condensation and accretion in the nebula, although we cannot exclude the possibility that some volatile loss occurred in the parent body during the process of melting and core formation.

Fractionation during core solidification

One question remains. If the volatility of Sb is nearly as great as that of Ga, why is it not 'quantised' to nearly the same degree? The answer is to be found in Fig. 3, which shows Ga–Ni, Ge–Ni and Sb–Ni distributions in IIIAB, the largest iron meteorite group. Whereas the Ga and Ge maximum/minimum ratios are 1.3 and 1.6, respectively, that for Sb is about 5. As discussed by Scott[12] and Wasson[13], there is little doubt that the element–Ni patterns in IIIAB formed by fractional crystallisation of a molten core. During fractional crystallisation elements having solid/liquid distribution coefficients near unity undergo minor fractionations, whereas those having more extreme distribution coefficients undergo large fractionations. This statement

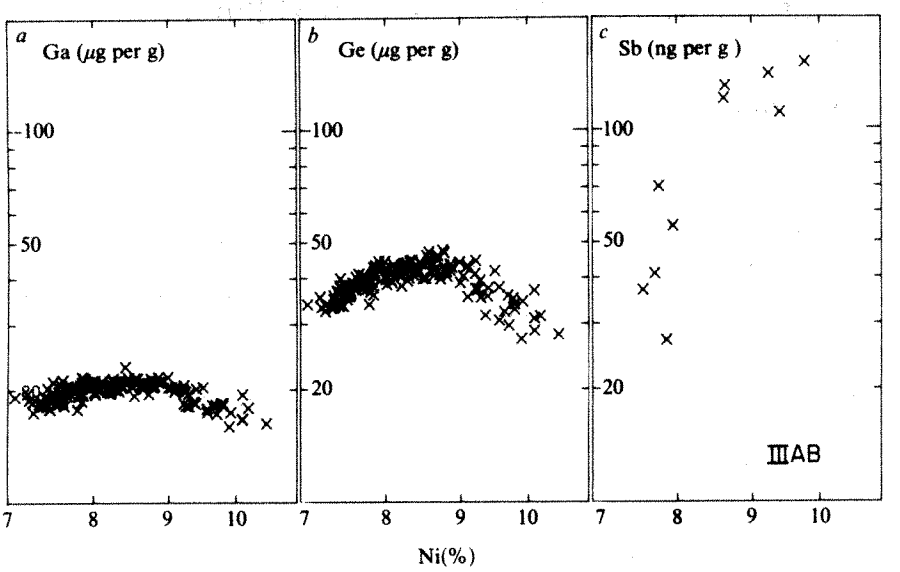

Fig. 3 A detailed comparison of the Ga–Ni (*a*), Ge–Ni (*b*) and Sb–Ni (*c*) distributions in group IIIAB. The small range of Ga and Ge produced during fractional crystallisation results from solid/liquid distribution coefficient near unity (slightly below 1 at low Ni, above 1 at high Ni concentrations). The larger Sb range (factor of 5) reflects a distribution coefficient distinctly different from unity (the estimated value is 0.44).

remains correct even if partial melting or fractional melting were responsible for the observed fractionations.

The distribution coefficient of Ni seems to have remained constant at ~0.90 during the fractional crystallisation of most iron meteorite cores[12,22]. Given this value one can calculate the distribution coefficients of elements linearly related to Ni on log–log plots. For example, the negative linear correlation of Ir and Ni in IIIAB leads to a distribution coefficient of 4.1 and a remarkable maximum/minimum ratio of 2,000. The positive linear correlation between Sb and Ni (Fig. 3) leads to a distribution coefficient of 0.44 and a maximum/minimum ratio of about 5.

In contrast, Ga and Ge are not linearly related to Ni. At low Ni concentrations the slope is positive indicating a distribution coefficient below 1 and at high concentrations it is negative indicating a distribution coefficient above 1. The iron meteorite groups originating in cores show positive Ga– and Ge–Ni correlations at low Ni concentrations, and groups IIAB and IVA also show the shift to negative slope at high Ni concentrations. In all 11 cases the maximum/minimum ratios are <2, indicating distribution coefficients near 1. The core-origin group other than IIIAB in which the Sb–Ni distribution is reasonably well defined is IIAB: its Sb range is a factor of 3. Fragmentary data for other groups indicate that ranges of 3–5 are typical for Sb (ref. 41).

Conclusion

The quantisation of Ga and Ge that is so important for the classification of iron meteorites resulted from the fortuitous combination of high nebular volatility, homogenisation during core formation, and low degrees of fractionation during fractional crystallisation of the solidifying cores.

We thank Bruce Fegley, John Willis and Ed Scott for unpublished data and useful discussions, and John Larimer, John Lewis and Derek Sears for informative reviews. This research was supported by NASA.

Thionine coated electrode for photogalvanic cells

W. John Albery, Andrew W. Foulds, Keith J. Hall & A. Robert Hillman
Department of Chemistry, Imperial College, London SW7, UK

Inorganic Chemistry Laboratory, South Parks Road, Oxford, UK

The successful operation of a photogalvanic cell for solar energy conversion requires that the illuminated electrode should discriminate between the two redox couples in solution. In the iron–thionine system the electrode must oxidise photogenerated leucothionine but not reduce the photogenerated Fe(III). Modified electrodes with coatings of thionine of up to 20 monolayers can be prepared on Pt and SnO_2. Electrode kinetic results for the Fe (III) and thionine systems show that this modified electrode is suitable for the iron–thionine photogalvanic cell.

THE criteria required for a successful photogalvanic cell for solar energy conversion has been discussed elsewhere[1]. The reaction scheme of the iron–thionine system for such a cell works as follows:

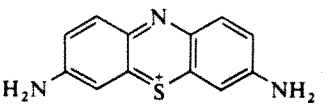
$$\mathrm{Th} \xrightarrow{h\nu} \mathrm{Th}^*$$

$$\mathrm{Th}^* + \mathrm{Fe(II)} \xrightarrow[\mathrm{H}^+]{} \mathrm{S}^{\cdot} + \mathrm{Fe(III)}$$

$$\mathrm{S}^{\cdot} + \mathrm{S}^{\cdot} \rightarrow \mathrm{Th} + \mathrm{L}$$

Illuminated electrode

$$\mathrm{L} \rightarrow \mathrm{Th} + 2\mathrm{e} + 3\mathrm{H}^+$$



Dark electrode

$$2\mathrm{Fe(III)} + 2\mathrm{e} \rightarrow 2\mathrm{Fe(II)}$$

where Th is

L is

and S˙ is the semithionine radical.

To obtain power from the cell the illuminated electrode must be able to discriminate between the photogenerated leucothionine (L) and Fe(III)[1,5]. If the electrode does not discriminate, then addition of the electrode reactions in the reaction scheme shows that the electrode merely catalyses the back reaction of photogenerated products into the original reactants:

$$L + 2Fe(III) \rightarrow Th + 2Fe(II)$$

The illuminated electrode must remove one of the photogenerated products, in this case L, and force the other, Fe(III), to diffuse across the cell and react on the dark electrode. Note that for an efficient photogalvanic cell the electrode kinetics of the two electrodes must be different[5]. If the Fe(III) reaction is blocked on the dark electrode, as well as the illuminated electrode, then the cell operates only as a concentration cell and produces insufficient voltage of $\sim RT/F$ (ref. 6). We describe here how to modify the illuminated electrode by coating it with thionine itself. The modified electrode then discriminates between the photogenerated L and Fe(III). A photogalvanic cell with a modified and an unmodified SnO_2 electrode will then possess the necessary differential electrode kinetics[7]. The properties of the modified thionine electrode are also interesting in that the electrode discriminates between the organic and inorganic couples studied. The reason for this discrimination will be discussed.

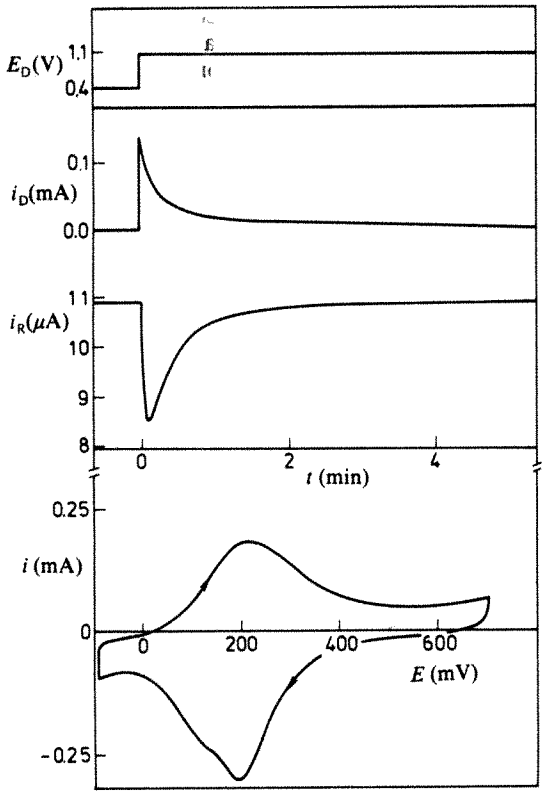

Fig. 1 Ring disk study of coating process and cyclic voltammogram of resulting thionine coated Pt electrode in 0.05 M H_2SO_4 containing no thionine. E_D is the disk potential, i_D the disk current and i_R the ring current.

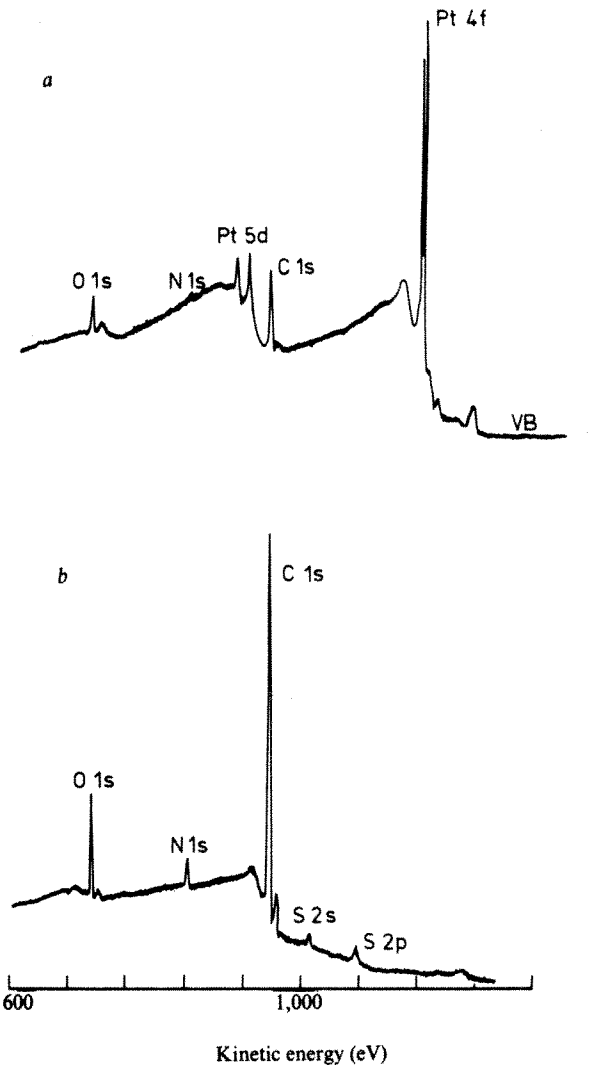

Fig. 2 Typical XPE spectra. *a*, Pt electrode that has been exposed to thionine solution at 0.4 V. The principal feature is the Pt 4f signal. *b*, Pt electrode coated at 1.1 V. The Pt 4f signal is suppressed; C, N and S corresponding to thionine are found.

Experimental methods

All the electrochemical experiments were carried out at 25 °C and all potentials reported with respect to the saturated calomel electrode. Rotating disk and ring-disk studies were performed using an Oxford Electrodes motor controller, rotating assembly and control electronics. Antimony doped SnO_2 electrodes were prepared by spraying a solution of 10 cm^3 $SnCl_4$ and 0.6 cm^3 $SbCl_5$ added to 20 cm^3 ethyl acetate for 3 s on to the end of a quartz rod heated to 1,000 °C and rotating at 5 Hz. Spectra were recorded on a Unicam SP 600 recording spectrophotometer. XPE spectra were measured on an AEI ES 200 B photoelectron spectrometer using MgKα exciting radiation; the base pressure was $\sim 10^{-9}$ torr. The conductance of the thionine coating was measured in the d.c. mode after vapour deposition of a Au contact.

Results and discussion

Preparation and properties of modified electrodes: both Pt and SnO_2 electrodes can be coated with a stable layer of thionine by holding the electrode at 1.1–1.5 V for several minutes in a solution containing thionine. Figure 1 shows a ring–disk experiment which monitors the consumption of thionine during the coating process. The thionine is coated on to the disk electrode and this process is monitored by the downstream ring electrode. From the decrease in the transport limited current for thionine at the ring electrode we can calculate from $N^{-1} \int \Delta i_R \, dt$

the amount of thionine consumed on the disk where N is the collection efficiency[8,9]. When the modified electrode is removed from the thionine solution, washed and placed in background electrolyte (such as 50 mM H_2SO_4) containing no thionine, cyclic voltamograms as shown in Fig. 1 are obtained. The peak height of these voltamograms varies linearly with sweep rate as expected for surface bound species. From the charge passed per cycle we can also calculate the amount of thionine in the layer. The coverages found from cyclic voltammetry agree with those from the ring–disk experiment but are usually about 20% lower. Coatings of up to 20 monolayers can be obtained and these coatings are stable in background electrolyte for at least several months. XPES studies, see Fig. 2, of a coated electrode show identical peaks to those of thionine and the Pt 4f peak is completely absent[10]. The cyclic voltamograms before and after the XPES experiment show that exposure to high vacuum for several hours only reduces the coverage by about 10%.

Compared with thionine in solution, the visible spectrum of a coated SnO_2 electrode on a quartz plate shows a broadened peak at much the same wavelength ($\lambda_{max}/nm \simeq 600$) (ref. 10). At reducing potentials this peak disappears. As shown in Fig. 3 the proportion of thionine, f, and leucothionine in the layer obeys the Nernst equation:

$$\frac{RT}{nF}\ln\frac{f}{1-f} = E - E_c' \qquad (1)$$

We find $n = 2$ and $E_c'/mV = 180$. This value is similar to that of thionine in our solution ($E'/mV = 208$). The resistance of 1 cm^2 of a layer coated at 1.1 V containing 6 nmol cm^{-2} was found to be 60 Ω. From these results we conclude: first, the layer consists of thionine or leucothionine depending on the electrode potential; second, the layer is remarkably stable and coherent, it cannot be washed off and the disappearance of the Pt signal in the XPE spectrum is particularly noteworthy; third, for current densities <150 μA cm^{-2} the voltage drop across the layer is <10 mV and can be neglected.

Thionine: We now examine the electrode kinetics of various redox couples on the thionine coated electrode starting with thionine. Figure 4 shows typical current–voltage curves for the reduction of thionine on a clean and a thionine coated Pt electrode. On the clean electrode the system is reversible. On the coated electrode the system is nearly reversible. Analysis of the current–voltage curves shows that the electrochemical rate constant is about 10 cm ks^{-1} for an electrode coated for 15 min at 1.1 V. Longer coating times or higher coating voltages result

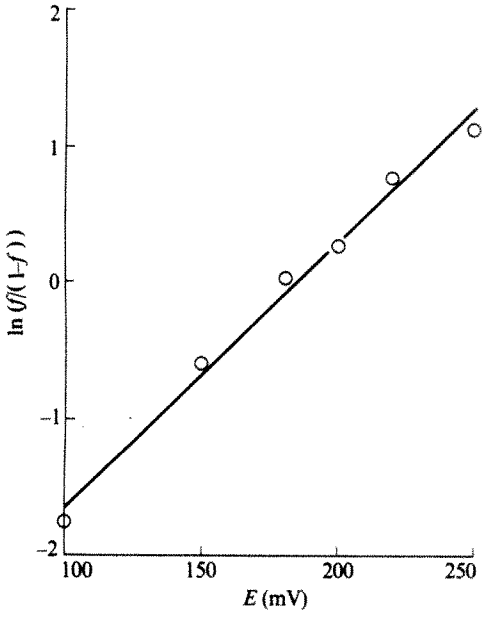

Fig. 3 Plot of Nernst equation (1) describing the bleaching of the thionine layer.

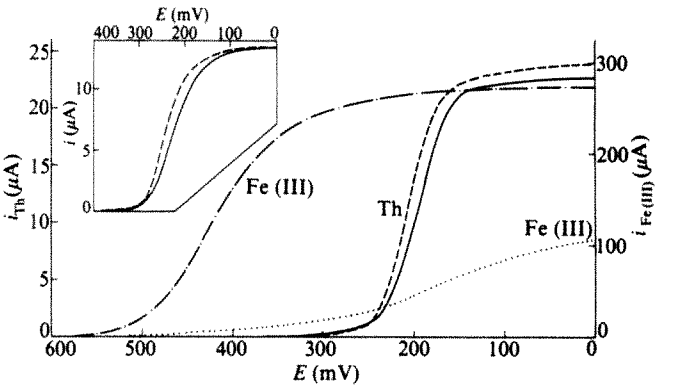

Fig. 4 Typical current–voltage curves for thionine (Th) and Fe(III) on an uncoated (– – – – – and – · – · – and a thionine coated Pt electrode (——— and .....). The inset shows similar current–voltage curves for disulphonated thionine.

in electrodes with lower electrochemical rate constants. For instance after coating for 1 h at 1.4 V the rate constant is about 1 cm ks^{-1}. Thus by choosing the coating voltage and time, the performance of the electrode can be controlled. We conclude first that on the coated electrode there is little difference between Pt and SnO_2 as the substrate surface. Second that the electrochemical rate constant is decreased for electrodes coated at higher voltages and for longer times. In particular there is a significant reduction in rate constant for electrodes coated at 1.4 V or above for periods longer than one hour.

Disulphonated thionine: photogalvanic cells have been extremely inefficient for the conversion of solar energy[11] because thionine is not sufficiently soluble to absorb the solar radiation close enough to the illuminated electrode[4]. We have recently synthesised 3,6-disulphonated thionine. The solubility is increased so that solutions ~10^{-1} M can be prepared and the visible spectrum shows no evidence for dimer formation. The disulphonated thionine cannot be coated onto the electrode in the same way as thionine. However, as shown in Fig. 4, the electrode kinetics of disulphonated thionine are very similar to those of thionine. Hence the thionine coated electrode can be used in a photogalvanic cell that operates with the more soluble disulphonated thionine.

Quinone: we investigated the reduction of quinone on the thionine coated electrode and found that the coating had practically no effect. A clean electrode and an electrode coated for 15 min at 1.4 V gave the same rate constant of 0.2 cm ks^{-1}. Hence thionine coating makes little difference to this typical organic redox system.

Fe(III): turning to inorganic couples, we find that the thionine coating makes a very significant difference to the electrode kinetics. We start with the reduction of Fe(III), which is the reaction that we wish to block in the photogalvanic cell.

Typical current–voltage curves for the reduction of Fe(III) are shown in Fig. 4. The coating produces first a shift of some 200 mV in the half wave potential and second the limiting current of the shifted wave is very much less than that on the untreated electrode. The variation of the limiting currents, i, of the shifted waves with rotation speed, W, are plotted in Fig. 5 according to the Koutecky Levich[12] equation:

$$\frac{nAF[\text{Fe(III)}]}{i} = \frac{0.65D^{-2/3}\nu^{1/6}}{W^{1/2}} + \frac{1}{k_7} \qquad (2)$$

where n is the number of electrons transferred; A, the electrode area; F, the Faraday constant; D, the diffusion coefficient of the electroactive species; ν, the kinematic viscosity; and k_7 the heterogeneous rate constant for the additional rate limiting step.

In equation (2) the term in the rotation speed, $W^{1/2}$, dominates the right hand side when the limiting current is controlled by mass transport. On the other hand the intercept of Fig. 5 gives the term in k_7 which corresponds to the control of the

limiting current by a kinetic process at the electrode which is independent of potential. Analysis of the current–voltage curves shows: first, that the coating has reduced the electrochemical rate constant by 10^{-2}; second that the transfer coefficient α is still $\frac{1}{2}$; and third that the limiting current is controlled by a second kinetic process described by k_7.

A reaction scheme of the following type would explain the data,

$$\text{Fe(III)} + L_{ads} \xrightarrow{k_7} \text{Fe(III)}L \xrightarrow[e]{k'} \text{Fe(II)}$$

where k_7 describes the formation of a complex between Fe(III) and coated leucothionine while k' describes an electron transfer with $\alpha \simeq \frac{1}{2}$. The fact that $\alpha \simeq \frac{1}{2}$ suggests that that the potential dependent rate constant is describing an electron transfer, even though the rate is much slower on a coated electrode compared to a clean electrode. The conductivity of the thionine film means that there cannot be large potential differences within the film and hence the main potential drop occurs at the thionine/water interface. We find that although Fe(III) has a different electrode kinetics on clean Pt (fast) and clean SnO_2 (slow), there is not much difference once the electrodes are coated. These results will be discussed further below.

$Fe(CN)_6^{4-}$: results for the oxidation of $Fe(CN)_6^{4-}$ in 0.4 M K_2SO_4 at *p*H 7 are similar to those for Fe(III). On a clean Pt electrode as expected the couple is reversible but on a coated electrode the wave is irreversible and again there is a second step. For an electrode coated at 1.1 V for 15 min we find $k_0'/\text{cm ks}^{-1} \simeq 0.6$ and $k_7/\text{cm ks}^{-1} \simeq 2.2$. It is very striking how the thionine coat has blocked this normally rapid electron transfer.

$Ru(bpy)_3^{3+}$: even more dramatic are the results for the reduction of $Ru(bpy)_3^{3+}$ in 0.5 M H_2SO_4 (where bpy is 2,2′ bipyridine). Results on a coated electrode are shown in Fig. 6. On a clean electrode $Ru(bpy)_3^{3+}$ is reduced at potentials <1.0 V, in a reversible wave. The thermodynamics for the reduction are favourable and the kinetics are rapid. However, on the coated electrode the transport limited current is not reached until 0.30 V. The current–voltage curve shows that there are two parallel processes. For potentials >0.40 V we find a small current which increases gradually as the potential decreases. A reasonably straight Tafel plot is obtained with a low value of $\alpha = 0.05$. At 0.4 V a second process takes over and the current rises rapidly to its transport limited value. Analysis of this part of the current–voltage curve gives $\alpha \simeq 2$. This high value of α cannot be caused by driving the electron transfer for the reduction of Ru(III). For that reaction we would expect (as was found for Fe(III)) that $\alpha = \frac{1}{2}$, and in any case α must be <1. We propose that the second process is the reaction of Ru(III) with L formed on the outside of the layer:

$$3H^+ + \underset{f}{\text{Th}} + 2e \rightleftarrows \underset{1-f}{\text{L}}$$

$$\underset{1-f}{\text{L}} + Ru(bpy)_3^{3+} \xrightarrow{k'} S^{\cdot} + Ru(bpy)_3^{2+} + 2H^+$$

The very small fraction of L ($\sim 2 \times 10^{-3}$) present when the second process takes over can be estimated from the Nernst equation (1) and the value of E_c' for 0.5 M H_2SO_4 where $E_c'/V = 0.270$. Figure 3 shows that the oxidation state of the thionine layer obeys the Nernst equation, and so we can calculate the current–voltage curve in Fig. 6 using the parameters derived from the analysis. Although our model for the second process fits the data very well, we do not yet have a detailed model for the slow process occurring at potentials >0.4 V. The very low value of α means that the process is not a straightforward electron transfer. This process may be similar to the k_7 step in the reduction of Fe(III). The potential range over which we can observe the k_7 process for Fe(III) is too restricted to be certain if k_7 depends slightly on potential or not.

Ce(IV): the reduction of Ce(IV) resembles that of $Ru(bpy)_3^{3+}$. Again two processes are evident. Following the same analysis as for $Ru(bpy)_3^{3+}$ we find that the steep part gives a curved Tafel plot with α varying between 1.4 and 2.0. The fact that these values are >1 suggests that we must again be seeing a reaction between L in the coat and Ce(IV).

Effect of coating voltages and coating times: Our interest in photogalvanic cells has led us to investigate the thionine and Fe(III) systems in more detail. We find that there is some reduction in the kinetic parameters the higher the coating voltage and the longer the coating time. We have found that there is a good correlation between the electrochemical rate constants for thionine or for Fe(III) and k_7. As these rate constants describe different processes we assume that the correlations arise through a general effect of the higher voltage or coating time on the coat itself. This affects all three processes, the reduction of thionine, the electrochemical step and the k_7 step in the reduction of Fe(III), to much the same extent. The higher coating voltages and coating times may cause this, for instance, by blocking off active sites on the surface.

Inorganic electron transfers: While the coat seems to have no drastic effect on the reduction of thionines or of quinone, single electron transfers to inorganic ions which normally proceed by outer sphere mechanisms are in all cases blocked by the coat. This is probably because the thickness of the coat prevents the direct tunnelling of electrons from the metal or SnO_2 to the solvated inorganic ion. For strong oxidising agents like Ru(III)

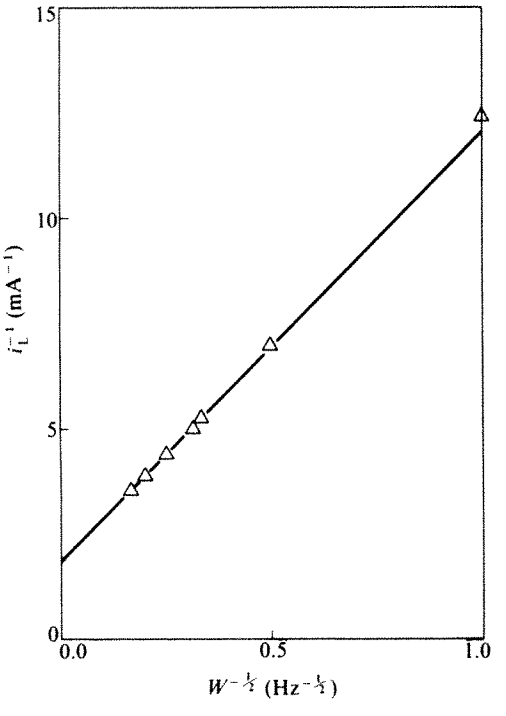

Fig. 5 Koutecky Levich plot, equation (2), for reduction of Fe(III) at thionine coated Pt electrode.

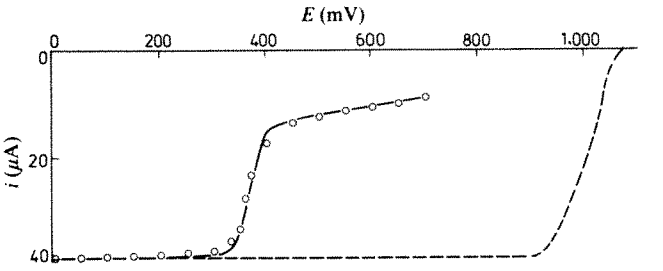

Fig. 6 Current–voltage curves for reduction of $Ru(bipy)_3^{3+}$ on a clean (– – – –) and a coated (○) Pt electrode. The solid line is the calculated curve for the two parallel processes discussed in the text.

and Ce(IV) the main path for reaction is apparently the oxidation of leucothionine on the outside of the coat. For Fe(III), because there is not such a strong thermodynamic driving force, the reaction between Fe(III) and L is 7 orders of magnitude slower than diffusion control. Hence we apparently have a two step mechanism of which one step is an electron transfer and we suggest that the other is the formation of a 'complex' between Fe(III) and leucothionine at the surface. Such complexes have been found in homogeneous reactions between Fe(III) and L (ref. 13). Note that the half wave potential for the reduction of Fe(III) is close to that of E' for thionine suggesting that the conversion of thionine to leucothionine in the coat may well be necessary for the reaction.

Implications for photogalvanic cells: Finally we return to the question of the selectivity of these electrodes for use in photogalvanic cells. Figure 4 shows that the thionine coated electrode does have the required selectivity. The coating leaves the electrode kinetics of the thionine couple sufficiently rapid to handle the photogenerated leucothionine[4] but it blocks the reduction of Fe(III). Thus an illuminated electrode working at a potential where it is oxidising leucothionine will only have a small current caused by the simultaneous reduction of Fe(III). Hence we conclude that the thionine coated electrode is an ideal illuminated electrode for the iron–thionine photogalvanic cell. The fact that it can be made so easily and that it is relatively stable are added advantages.

We thank Dr R. Whiteside for preparing the disulphonated thionine; and the SRC for equipment grants and for studentships for A.R.H. and A.W.F. This is a contribution from the Oxford Imperial Energy Group.

Identification of the protein encoded by the transposable element Tn*3* which is required for its transposition

Ronald E. Gill, Fred Heffron* & Stanley Falkow

Department of Microbiology and Immunology, University of Washington, Seattle, Washington 98195

*Protein products have now been identified which account for the entire coding capacity of the transposable element Tn*3*. Mutations in Tn*3* have allowed us to map the genes encoding each of these peptides and to identify their role in transposition. We have found that only a single Tn*3*-encoded peptide is required for transposition. Expression of this peptide is repressed by the product of a second gene, which is itself autogenously regulated.*

PLASMID-MEDIATED antibiotic resistance in bacteria has often been shown to reside on discrete DNA segments capable of transposition to other replicons in the cell (for review see refs 1–5). This event occurs in the absence of *rec*A-mediated recombination and does not require extensive regions of homology. One such transposable element, Tn*3* (refs 6–8) confers resistance to ampicillin by encoding for the production of the penicillin hydrolysing enzyme β-lactamase. This transposon is a particularly useful focus of study for the examination of the transposition process as a molecular event.

Analysis of mutants of the Tn*3* element[9,10] has resulted in a relatively simple map of the genetic organisation of the Tn*3* functions and structures necessary for its transposition and those related to the regulation of transposition frequency (Fig. 1). The element itself is about 5,000 base pairs in length. The 38 base pairs at each end are inverted and repeated sequences (IR)[11]. Mutations affecting either of the IR result in a transposition-deficient phenotype, and at least the left IR is required in *cis* (ref. 10). (The element will always be discussed in the orientation shown in Fig. 1.) The structural gene for the β-lactamase enzyme (*bla*) maps to the far right end of the transposon[9,10] (Fig. 1). Adjacent to the *bla* gene and bisected by the *Bam*HI restriction site, is the part of the transposon which we refer to as the 'regulatory region'. This region is known to consist of at least one gene, which we designate *tnpR*, which encodes a *trans*-acting 19,000-molecular weight (MW) peptide that represses the level of Tn*3* transposition[9,10,12,13]. Adjacent to the regulatory region and extending to the left IR is a 3000-base pair stretch of DNA which encodes one or more *trans*-acting functions necessary for Tn*3* transposition[9,10,12]. For convenience, we shall refer to this segment of the element as the 'transposase' region. This terminology, however, is only descriptive of the phenotype of mutations which saturate this region of the Tn*3* map; it is not meant to imply any particular enzymatic activity for the functions encoded by this region.

The genetic map of Tn*3* had been formulated from the analysis of two sets of Tn*3* mutants[9,10]. Both were the result of *in vitro* manipulation of the plasmid RSF1050, a small derivative of ColE1 into which Tn*3* had been transposed. The first set of RSF1050 mutants contained various-sized deletions having one or both endpoints within the transposon[9]. The newer collection was constructed by random *in vitro* insertion of an oligonucleotide containing an *Eco*RI restriction site into the Tn*3* element[10]. We will refer to this collection of mutants as '*Eco*RI-insertion mutants'. Many of the *Eco*RI-insertion mutants have now been sequenced (F. Heffron *et al.*, in preparation). It was found that, in addition to the insertion of the *Eco*RI site oligonucleotide, a small deletion or duplication of Tn*3* sequences occurred at the site of the insertion. However, none of these was greater than 50

base pairs. The result is that many of the mutations shift the translational reading frame distal to the mutation. These would, therefore, be expected to have the same utility as frameshift mutations for mapping location and direction of gene transcription. Other *Eco*RI-insertion mutations have been found to retain the original reading frame and so will be expected simply to result in the addition of a few amino acids to the translation product at the point of the mutation.

These mutants were used to map the *tnpR* gene and study its regulation of transposition frequency. They have also allowed us to identify the peptide encoded by the 'transposase' region of the element.

Genetic analysis identifies only a single Tn*3* gene necessary for its transposition

Previous analyses of Tn*3* mutants have shown that all of the recessive transposition-deficient (Tnp$^-$) mutants are clustered in the transposase region of the element[9,10]. To establish a genetic basis with which to approach the biochemistry of transposition, we wished to determine the number of functions encoded by this region which are required for transposition to occur. Therefore, we initially attempted a complementation analysis of these Tnp$^-$ mutants.

To use the existing Tn*3* mutants, which were all isolated on the plasmid RSF1050, it was necessary to circumvent the problem of plasmid incompatibility when testing pairs of these mutants for complementation. Therefore, a number of Tnp$^-$ deletion or insertion mutants of Tn*3* were transposed by complementation by wild-type Tn*3* on to a plasmid compatible with RSF1050; either JCFL4 (F' *lac* $tra_{am}K4$)[14], or a non-colicinogenic derivative of the plasmid ColK (provided by D. Sherratt). These plasmids were then introduced into *rec*A$^-$ cells containing a conjugative plasmid and representative RSF1050Tnp$^-$ mutants. Strains containing each of the combination of Tn*3* mutants were tested for complementary transposition using the mating assay described previously[9,12]. In this manner, 5 deletion and 16 *Eco*RI-insertion mutants spanning the transposase region were tested in pairwise combinations for complementation. Data for representative Tnp$^-$ mutants are shown in Table 1. Although the assay was sensitive enough to detect transposition at a frequency of at least 1% of the wild type, these experiments failed to detect complementation between any of the pairs of mutants tested. These results indicate that Tn*3* encodes only a single *trans*-acting function in the transposase region, although other explanations could not be eliminated by these experiments.

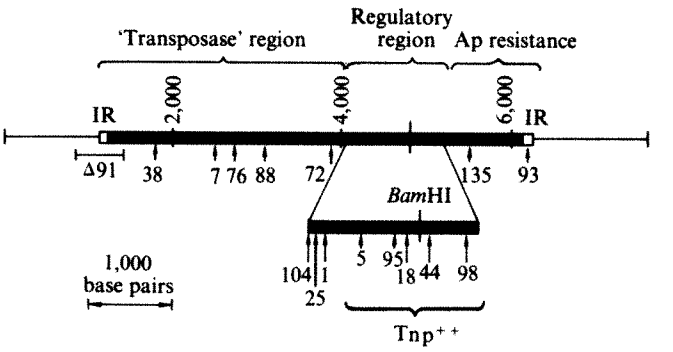

Fig. 1 Map of the Tn*3*-containing plasmid RSF1050[9,10]. The plasmid is shown as a linear molecule after cleavage at the *Eco*RI site in the ColEl portion of the molecule. The Tn*3* element is indicated by the bold line; ColEl-derived sequences are denoted by the thin line. The inverted and repeated termini of the element, labelled IR, are denoted by an open box. The Tn*3* element is divided into three sections based on the phenotype of mutations which map there, as explained in the text. Arrows (↑) denote location of *Eco*RT-insertion mutations[10]; each is identified by its pFH number. pFH7, pFH76 and pFH88 are Tnp$^-$; those mapping to the regulatory region are Tnp^{++}; pFH135 has lost the ability to confer resistance to ampicillin; pFH93 is a *cis*-dominant Tnp$^-$ mutation affecting the right IR, which is able to complement mutations in the 'transposase' region; mutation Δ91 is a deletion which removes about 300 base pairs of Tn*3*, including the left IR (F. Heffron *et al.*, in preparation).

Identification of Tn*3*-encoded peptides in minicells

We next attempted to confirm our genetic evidence for a single function encoded by the Tn*3* transposase region by visualising its protein products directly. Dougan *et al.*[13] have reported the

Table 1 Complementation of Tn*3* mutants

		RSF1050 derivative					
	JCFL4 derivative*	A RSF1050$^+$	B pFH72	C pFH88	D pFH7	E pFH38	Comments
1	JCFL4	(—)	0	0	0	0	Negative control. The level of transportation of Tn*3* from the Tnp$^-$ mutants of RSF1050 was below the limit of detection (0.5×10^{-6} or a normalised value of 0.004)
2	JCFL4::Tn*3*-135$^+$	1.0	0.3	0.1	0.4	0.1	Positive control. Tnp$^-$ mutants were complemented in *trans* by a transposition proficient Tn*3* element on JCFL4†
3	JCFL4::Tn*3*-72	1.0	0.0009	0.006	0.001	0.003	The Ap^r transconjugants reported in columns B–E had received the JCFL4 derivative and represent reversion or supression of the *traK4* mutation on the F'*lac*. No transposition on to R388 was detected
4	JCFL::Tn*3*-38	1.0	0.002	0.001	0.007	0.003	

Complementation experiments were attempted using strain M1653 (*rec*A$^-$, Su^0) containing the conjugative plasmid R388 (trimethoprim and sulphonamide resistant) plus representative Tnp$^-$ mutants of RSF1050. The plasmid JCFL4 (F'*lac traK4*) into which representative Tnp$^-$ mutants of Tn*3* had been transposed was then introduced into these strains. JCFL4 was not transmissible from the Su^0 strain, M1653. Therefore, transposition (by complementation *in trans*) of either of the mutant Tn*3* elements into the co-resident conjugative R388 plasmid could be measured by selecting for the transfer of Ap^r into a suitable recipient in a 4 h mating. The frequency of transposition was: no. of Ap^r transconjugants/total no. of transconjugants. Representative data are presented for four Tnp$^-$ mutants of RSF1050 (columns A–E) and two Tnp$^-$ mutants of Tn*3* on JCFL4 (lines 3 and 4). The values entered into the table were normalised to the frequency of transposition of wild-type Tn*3* from RSF1050 (1.3×10^{-3}) which was given a value of 1.0.

* Locations of the respective mutations in Tn*3* are shown in Fig. 1.

† Tn*3*-135 (ref. 9) is a Tn*3* derivative which has a determinant encoding tetracycline resistance cloned into and inactivating the ampicillin resistance gene. Transposition functions have not been detectably altered. Use of this element made it possible to directly select for the complemented transposition of the co-resident Tnp$^-$ (Ap^r) element on RSF1050.

use of *Escherichia coli* minicells[15] containing RSF1050 or representative RSF1050 deletion mutants to identify polypeptides encoded by defined regions of the Tn*3* element. These investigators reported, however, that no protein encoded by the transposase region of the element was synthesised in detectable amounts by minicells. The functions encoded by this region are presumably repressed by the wild-type element[10,12].

E. coli minicells were also used here, but advantage was made of several recently isolated transposition-proficient mutants of Tn*3* which had lesions confined to the regulatory region of the element[10]. These mutations resulted in a 10–50-fold increased frequency of transposition of the mutant element, and were recessive to wild-type Tn*3* for this behaviour (ref. 10, R. E. G., unpublished observation). The phenotype of these mutants, designated Tnp^{++}, suggests that they possess mutations which allow increased expression of the function(s) encoded by the transposase region.

Five of the Tnp^{++} mutants of RSF1050 used in this study were from the collection of *Eco*RI-insertion mutants isolated by Heffron *et al.*[10] (see Fig. 1). The remaining Tnp^{++} mutant was prepared by enzymatic manipulation of the *Bam*HI restriction site of Tn*3*. *Bam*HI cleaved RSF1050 only once, at a site in the Tn*3* regulatory region, generating a linear molecule with single-stranded 5′ protruding ends. These ends were made double stranded by polymerising the complementary strand with T4 DNA polymerase. This manipulation introduced a 4-base pair duplication at the *Bam*HI site: G$^{\downarrow}$GATCC to GGATC*GATC*C. Consequently, a frameshift mutation was introduced into the gene encoded at that point. As the mutant sequence was no longer cleaved by *Bam*HI, the mutant element will be referred to as a *Bam*HI^{0} mutant.

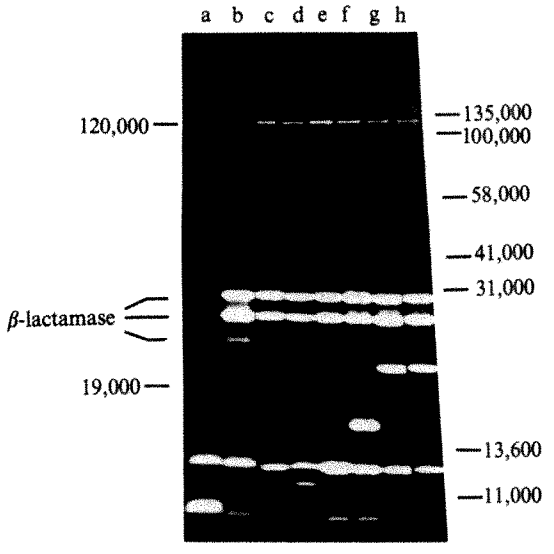

Fig. 2 Identification of Tn*3* encoded peptides. Minicells were purified[22] from cultures of *E. coli* DS410[23] containing the plasmid RSF1050 or Tnp^{++} mutants of RSF1050. Proteins were labelled in M9 minimal media with 30 μCim^{-1} of ^{35}S-methionine for 45 min. Minicells were collected and lysed by boiling in 80 μl of cracking buffer (50 mM Tris-HCl, *p*H 6.8, 1% SDS,, 1% β-mercaptoethanol, 5% glycerol). The proteins were precipitated by addition of 1.2 ml of acetone for 20 min at room temperature. The precipitate was pelleted and resuspended in final sample buffer (0.0626M Tris, *p*H 6.8, 3% SDS, 5% β-mercaptoethanol, 10% glycerol), and boiled 3 min. Approximately, 60,000 c.p.m. were applied to each well of a 10–18% gradient SDS polyacrylamide gel[19], and electrophoresed at 130 V until the dye reached the bottom of the gel. Gels were prepared for fluorography as described[24] and exposed for 18 h at −70 °C. Samples were prepared from minicells carrying the following plasmids: Lane a, pMB8, which is the ColEl derivative into which Tn*3* was transposed to make the plasmid RSF1050; lane b, RSF1050, (pMB8 :: Tn*3*, wild type); lanes c–h Tnp^{++} mutants pFH5, pFH95, a *Bam*H1^{0} mutant of RSF1050, pFH44, pFH18 and PFH98, respectively. Location of each mutation is shown in Fig. 1. Migration of molecular weight standards is shown on the right margin. Standards were: *E. coli* β-galactosidase, MW 135,000; phosphorylase *b* (rabbit muscle), MW 100,000; catalase (beef liver), MW 58,500; alcohol dehydrogenase (horse liver), MW 41,000; DNase 1 (bovine pancrease), MW 31,000; RNase A (bovine pancrease), MW 13,600; cholera toxin B subunit, MW 11,000. The 120,000 and 19,000-MW peptides from Tn*3* and the three forms of the β-lactamase gene product are identified in the left margin.

We have examined the Tn*3* specific polypeptides synthesised in *E. coli* minicells carrying each of the RSF1050 Tnp^{++} mutants (Fig. 2). Peptides encoded by wild-type Tn*3* can be identified by comparing lane a, pMB8, with lane b, RSF1050 (pMB :: Tn*3*). The β-lactamase gene product, which is known to undergo post-translational processing[16,17] resolves into three discrete bands with our electrophoresis conditions (also see ref. 13). Minicells carrying wild-type Tn*3* (lane b) also synthesise a 19,000-MW peptide. This peptide was shown by Dougan *et al.*[13] to be encoded by the Tn*3* regulatory region by the gene we designate here as *tnpR*. They also observed the correlation that Tn*3* mutants having the phenotype of increased transposition frequency failed to produce this 19,000-MW peptide.

In contrast to the wild-type element, the 19,000-MW peptide is not synthesised in minicells carrying any of the Tnp^{++} mutants (Fig. 2, lanes c–h). Minicells containing pFH5, PFH95, a *Bam*HI^{0} mutant of Tn*3*, or pFH44 (Fig. 2, lanes c–f) each produced an additional prominent peptide which we interpret to be truncated forms of the 19,000-MW *tnpR* gene product. The truncated peptide encoded by pFH5 has eluted off the gel, but those encoded by pFH95, the *Bam*HI^{0} mutant, and pFH44 migrated with apparent molecular weights of 11,500, 12,500 and 15,500, respectively. The peptide from the *Bam*HI^{0} mutant co-migrated with a peptide encoded by the pMB8 portion of RSF1050 in these electrophoretic conditions. The size of the truncated peptide encoded by each of the mutants is related to the map position of the mutation in such a way as to suggest that transcription of *tnpR* proceeds rightward and that the initiation of translation corresponds to the 4,200 base pair coordinate of RSF1050 (Fig. 1). This is between the mutation in pFH1 and pFH5, supporting the observation that mutation 1 does not lie in the *tnpR* gene itself (see below).

Minicells containing the Tnp^{++} mutants pFH18 and pFH98 also fail to synthesise a 19,000-MW peptide (Fig. 2, lanes g, h). However, each encodes a new peptide slightly larger than this. These peptides have been shown to be highly related to the wild-type protein by comparison of the fragments generated by partial chymotrypsin or *Staphylococcus aureus* V8 protease cleavage[18] of each of the respective peptides (data not shown). The nucleotide sequence surrounding mutations 18 and 98 have been determined (F. Heffron *et al.*, in preparation). Mutation 18 was found to preserve the transcriptional reading frame of the distal portion of the *tnpR* gene, but had an insertion at the site of the mutation sufficiently large to account for the synthesis of the observed peptide. A somewhat similar explanation accounts for the observed peptide encoded by pFH98.

Dougan *et al.*[13] have previously observed that truncated forms of the 19,000-MW peptide from *tnpR* mutants of the Tn*3* were overproduced in minicells. Results shown in Fig. 2 tend to corroborate that observation, at least for pFH44, pFH18, pFH98 and the *Bam*HI^{0} mutant. As measured by the density of the band image on fluorograph negatives, considerably more radioactivity was incorporated into the mutant *tnpR* products than into the wild-type 19,000-MW peptide. It seems, therefore, that the *tnpR* gene product represses the level of its own expression, as well as repressing the level of transposition.

Interestingly, the fluorograph in Fig. 2 also clearly shows that minicells containing any of the Tn*3* mutants which affect the 19,000-MW peptide (lines c–h) synthesise a previously undetected high molecular weight peptide. This peptide migrates between β-galactosidase (MW 135,000) and phosphorylase *b* (MW 100,000) in 7.5% SDS polyacrylamide gels[19] and has an apparent molecular weight of 120,000. Disregarding the possibility of overlapping genes, the transposase region of the element is just large enough to encode a 120,000-MW protein, and is the only such stretch of DNA on the transposon for which no other protein product has been identified.

We have examined the effect of Tnp^{-} mutations on the synthesis of this peptide to determine if it was, in fact, the product of the transposase region. We have already shown that

this protein is only made in detectable quantities by transposons which have mutations in the *tnpR* gene. Therefore, representative Tnp⁻ deletion and *Eco*RI-insertion mutants of Tn*3* were also made *tnpR*⁻ by introducing a 4 base-pair insertion at the *Bam*HI site, as described above. The proteins encoded by these mutant elements were labelled in minicells and separated on SDS polyacrylamide gels (Fig. 3).

As expected of *Bam*HI⁰ mutants, each of the minicell strains produced the characteristic 12,500-MW truncated *tnpR* product. None of these doubly mutant elements directed the synthesis of the 120,000-MW peptide, however (Fig. 3, lanes c–f). Furthermore, only mutations in the transposase region abolished synthesis of this peptide; *Bam*HI⁰ mutants of elements having *Eco*RI-insertion mutations elsewhere in the element, either in the β-lactamase gene (mutant 135) or in the right IR (mutant 93) continued to direct the synthesis of the 120,000-MW peptide (data not shown). These results indicate that the transposase region itself encodes the 120,000-MW peptide expressed in the *tnpR*⁻ mutants of Tn*3*. We have designated the gene encoding this peptide *tnpA*.

The *Eco*RI-insertion mutants used in Fig. 3 were selected because DNA sequencing had shown that they led to a shift in the transcriptional reading frame of the *tnpA* gene (F. Heffron *et al.*, in preparation). Thus, they could be used to determine the location of the ends of the *tnpA* gene and the direction of its transcription. Minicells containing *Bam*HI⁰ mutants of pFH7, pFH76[10], and pFH88 (lanes d–e) synthesised unique 60,000, 52,000 and 37,000-MW peptides, respectively. The molecular weight of these unique peptides correlated with the map position of the mutations in such a way as to suggest that the *tnpA* gene is transcribed leftward on the Tn*3* map in Fig. 1. Assuming that an amino acid has an average MW of 110, it was deduced that the beginning of translation of the *tnpA* gene product corresponds approximately to the 4,100 base pair coordinate of RSF1050, which in turn places the distal end of the gene very close to the left IR. The orientation of the *tnpA* gene was also deduced from the effect of the deletion Δ91 on the synthesis of the 120,000-MW peptide. Δ91 deletes ~300 base pairs of the left end of Tn*3* including the left IR (Fig. 1). This deletion reduced the molecular weight of the peptide from 120,000 to 105,000, presumably by removing the distal portion of the gene. It is interesting to contrast the phenotypes of Tn*3* elements having the Δ91 deletion with that of the *Eco*RI-insertion mutant pFH93. Mutant Δ91 removes the left IR; mutation 93 interrupts the right IR (Fig. 1). Both are *cis*-dominant Tnp⁻ mutations, presumably because both the left and right IR are required for transposition. Mutation 93 did not affect the *tnpA* gene product, and was found to complement *tnpA* mutants of Tn*3* (data not shown). Deletion mutant Δ91, however, will not complement over Tnp⁻ mutants, presumably because of the removal of the distal portion of the *tnpA* gene. We have also examined three additional transposition-proficient *Eco*RI-insertion mutants, pFH104, pFH25 and pFH1, which map just to the left of the Tnp⁺⁺ mutations (Fig. 1). The peptides synthesised from minicells containing these mutant plasmids appear identical to those encoded by the wild-type element (data not shown). In addition to the β-lactamase peptides, each of the mutant plasmids directs the synthesis the 19,000-MW product of the *tnpR* gene, but not detectable amounts of the *tnpA* gene product. Expression of the 19,000-MW peptide is consistent with the observation that these three mutants retained the ability to repress the frequency of transposition of Tnp⁺⁺ (that is, *tnpR*⁻) mutants. It also supports our earlier placement of the proximal end of the *tnpR* gene between the mutations in pFH1 and pFH5. However, whereas pFH1 transposed at near wild-type levels, mutants pFH104 and pFH25 each transposed at an elevated frequency, intermediate between wild-type and the Tnp⁺⁺ mutants, and were apparently repressed by a wild-type element (R.E.G., unpublished observation). The observation that pFH25 and pFH105 transposed at an elevated frequency, even though functional *tnpR* gene product was being produced, was unexpected. We do not believe, however, that these mutants contradict our scheme for the regulation of Tn*3* transposition frequency. Indeed, DNA sequence analysis of these mutations (F. Heffron, *et al.*, in preparation) indicated that these mutations actually affect the proximal end of the *tnpA* gene. If this is the case, then the increased transposition frequency may reflect an alteration in the activity of the *tnpA* gene product, rather than in its regulation.

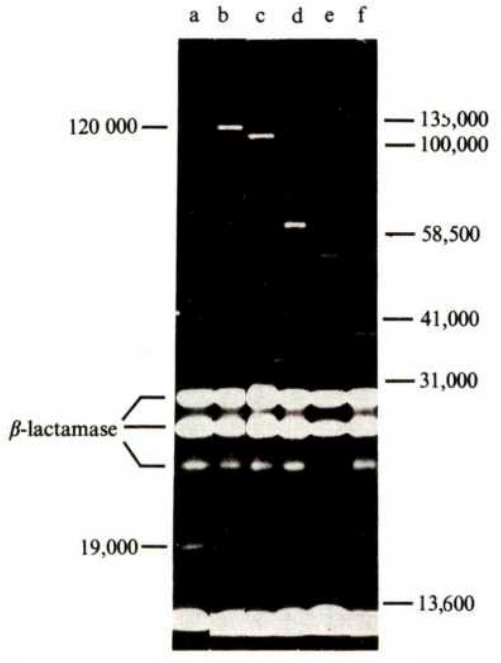

Fig. 3 Peptides synthesised in minicells containing transposition-deficient mutants of Tn*3*. Minicells were isolated, labelled and prepared for electrophoresis as in Fig. 2. Extracts were electrophoresed through an 11% SDS polyacrylamide gel at 100 V. Lane a, wild-type RSF1050; lane b, *Bam*HI⁰ mutant of RSF1050. Lanes c–f, RSF1050 derivatives which have a *Bam*HI⁰ mutation, as well as a mutation in the 'transposase' region of Tn*3*. The 'transposase' region mutations are: lane c, deletion 91; lane d, *Eco*RI-insertion mutation 7; lane e, *Eco*RI-insertion mutation 76, lane f, *Eco*RI-insertion mutation 88. Location of these mutations in Tn*3* is shown in Fig. 1. Molecular weight standards are those listed in Fig. 2 legend.

Fig. 4 Map Tn*3* showing location of its three genes. Arrows indicate direction of transcription. The size of the protein product of each gene is also indicated. Location of the *bla* gene and direction of its transcription are based on Heffron[9] and Sutcliffe[16]. Three peptides are associated with the β-lactamase gene in minicell extracts[14]. The largest of these, with MW of 29,000 when compared to our standards, is presumably the unprocessed *bla* gene product[16,17].

Conclusion

Tn*3*-specified proteins have now been identified which account for the entire coding capacity of the transposon. Our data indicate the presence of three genes encoded by the element as outlined in Fig. 4. The *bla* gene, encoding the β-lactamase enzyme, is situated at the right end of the element and is transcribed rightwards[9,16]. The remaining two genes, *tnpA* and *tnpR*, begin near the centre of the transposon and are transcribed in opposite directions. The position of these genes is consistent with the genetic organisation of the element as deduced from the DNA sequence of the element (F. Heffron *et al.*, in preparation).

The *tnpA* gene extends from its initiation near the centre of the element all the way to the left IR. All of the known recessive Tnp⁻ mutations of Tn*3* map in this gene. The existence of only a

single gene encoded by the transposase region is also supported by the observation reported here that recessive Tnp⁻ mutants appear to fall into a single complementation group. The product of the *tnpA* gene has been identified as a 120,000-MW peptide, which is expressed in detectable quantities by minicells containing only *tnpR*⁻ mutants of Tn*3*. As this peptide is required for transposition, its overproduction by *tnpR*⁻ mutants may account for the Tnp⁺⁺ phenotype of such mutants. Although necessary for transposition, no enzymatic function has yet been attributed to this peptide, and its possible interaction with host proteins has not been established.

The product of the *tnpR* gene is a 19,000-MW peptide. Our data are consistent with a dual regulatory role for this gene product. First, it appears to repress the level of *tnpA* expression. Overproduction of the 120,000-MW *tnpA* gene product by *tnpR*⁻ mutants presumably accounts for the elevated transposition frequency observed for these mutants. Second, the *tnpR* gene seems to regulate the level of its own expression. The mutant *tnpR* gene products are typically overproduced relative to the wild-type product. Regulatory proteins having such dual roles have also been observed for the *araC* gene[20] and *cI* gene of bacteriophage[21].

Transposition protein of Tn*3*: identification and characterisation of an essential repressor-controlled gene product

Joany Chou, Peggy G. Lemaux, Malcolm J. Casadaban & Stanley N. Cohen

Departments of Genetics and Medicine, Stanford University School of Medicine, Stanford, California 94305

Fusions that bring lac *gene expression under the control of transcriptional and translational signals within the Tn*3 *element have been used to identify and characterise a Tn*3*-encoded 'transposase'* (Tnp) *peptide of MW 100,000 essential for transposition. The gene specifying this product is regulated by the Tn*3 *repressor protein and is part of a bidirectional genetic unit that includes the repressor gene.*

Tn*3* is one of a class of genetic elements capable of transposition between DNA segments having no sequence homology with each other or with the transposable element itself[1]. This element encodes functions that affect its own transposition[2,3] as well as a β-lactamase gene that renders host bacterial cells resistant to the antibiotics penicillin and ampicillin[4].

Recently, we have used Tn*3*–*lac* gene fusions to identify and analyse regulatory mechanisms that control the transposition of Tn*3* (refs 5–7). Plasmids containing both Tn*3* and *lac* were constructed and deletions that fuse the *lac* genes to Tn*3* sequences were introduced, bringing expression of *lac* under control of transcriptional and translational signals within the transposable element. Such experiments have shown that a DNA region within Tn*3* that is known to influence its transposition frequency[2,3,8] encodes a peptide of molecular weight 21,000 (21K) that represses transposition of Tn*3* and acts at the level of transcription to regulate its own synthesis[7].

During our studies of the Tn*3*-encoded repressor gene, we observed a prominent increase in the synthesis of a 100K peptide in Tn*3* mutants that fail to synthesise a functional repressor, suggesting that the gene specifying this peptide might also be regulated by the repressor. Here we report the use of *lac* gene fusions to identify and characterise the gene encoding the 100K peptide. Our findings indicate that this peptide is a repressor-controlled product required for transposition of Tn*3* and that its gene is transcribed in a divergent direction from the adjacent repressor gene.

Identification of a Tn*3*-encoded 100K peptide

Gel electrophoresis (Fig. 1*a*) of extracts from ^{35}S-methionine-labelled minicells[9] containing a nonsense (R49) or missense (R102) mutation in the repressor peptide showed a large band having a calculated molecular weight of 100K for both types of repressor-minus mutants; little or no such peptide was seen in extracts of minicells containing the wild-type (repressed) Tn*3*.

The location and extent of the gene encoding the 100K peptide were identified using the pMC1102 and pMC1104 plasmids (Fig. 2), which carry Tn*3* elements that have deleted internal sequences, and the pMC823 plasmid, which has deleted all of Tn*3* to the right of the sixth codon of the repressor gene (ref. 7; see also Fig. 4 below). The pMC1102 and 1104 plasmids include the R49 amber mutation in the Tn*3* repressor gene. As seen in Fig. 1, pMC1102 (Δ*Bcl*I) and pMC1104 (Δ*Pst*I) (Fig. 1*b*) do not encode the 100K peptide whereas pMC823 does (Fig. 1*c*). This locates the 100K peptide gene between the left end of Tn*3* (IRa) and the beginning of the repressor gene, which is the only region of Tn*3* retained on pMC823. From the size of the 100K peptide, it can be calculated that almost this entire segment must be used to encode the peptide (Fig. 2). The orientation of the gene for the 100K peptide can be inferred from the size of the 66K truncated peptide (Fig. 1*b*) formed by the pMC1104 (Δ*Pst*I) deletion plasmid. The 66K peptide is too large to be encoded entirely to the left of Δ*Pst*I and too small to

0028-0836/79/510801—06$01.00

© 1979 Macmillan Journals Ltd

span it in frame. Thus, the NH_2-terminus of the 66K peptide can be assigned to the right of Δ*Pst*I, thus implying a right-to-left orientation for the gene. This assignment is consistent with the absence of a detectable truncated peptide for the pMC1102 (Δ*Bcl*I) deletion plasmid which retains only a very small part of the right end of the 100K gene.

Assignment of the gene for the 100K peptide gene to a location at the left end of Tn*3* (Fig. 2) exhausts the coding capacity of the transposon, unless overlapping or very small genes are present. Tn*3* is thus seen to encode three peptides—a β-lactamase[4,10], a self-regulated repressor protein[7], and the repressible 100K peptide.

The Δ*Pst*I and Δ*Bcl*I deletions, both of which fail to synthesise the 100K peptide (Fig. 1), do not undergo transposition at a detectable frequency even when coupled to a mutation (R49) in the Tn*3* repressor gene that otherwise leads to a 14-fold increase in the frequency of transposition (data not shown). This observation, together with earlier evidence[2,3] that deletions or insertions in the vicinity of these endonuclease cleavage sites prevent transposition, suggests that the repressor-controlled 100K peptide (hereafter termed 'transposase' or *Tnp* gene product) carries out functions essential to the transposition process.

The effects of repressor on synthesis of the Tnp protein are shown in Table 1. As seen in the table, missense and amber mutations in the Tn*3* repressor lead to a 10- and 60-fold increase in production of a missense repressor peptide or a nonsense truncated peptide respectively. The greater extent of derepression observed with the nonsense mutation (R49), which yields a truncated repressor peptide[7], compared with the missense mutation (R102), which results in the formation of a full-length peptide having a presumed amino acid substitution, could be explained if the peptide product of the missense mutant is partially functional. This interpretation is consistent with the observed fivefold increase of the Tnp peptide in the missense mutant versus the eightfold increase of the Tnp peptide in the two nonsense mutants examined.

Use of *lac* gene fusions for study of regulation of the Tnp protein

Introduction of a promoter-less *lac* gene segment within the *Tnp* gene provides a convenient assay for studying *Tnp* gene expression. In these experiments the segment of the *Tnp* gene between the two *Bcl*I sites of Tn*3* carrying the R49 mutation in the repressor gene was replaced (in the orientation shown for the pMC1103 plasmid, Fig. 2) by a *lac* gene-derived sequence (endonuclease-generated fragment 903 *lac*, ref. 11) that lacks a promoter but contains a translational start signal for the *lacZ* structural gene, which encodes the enzyme β-galactosidase. Expression of *lac* by pMC1103 (Table 3, line 1) verifies the proposed direction of transcription of the *Tnp* gene and demonstrates that the transcriptional start for this gene is located to the right of the $Bcl\text{I}_b$ site. When a plasmid carrying a wild-type Tn*3* (that is, the pACYC999 plasmid) was placed *in trans*, a decrease in β-galactosidase to 15% the level specified by the pMC1103 plasmid was observed; there was no change in the level of *lac* gene expression when a Tn*3* element carrying the R49 amber mutation was introduced *in trans*, demonstrating directly that transcription of the segment of the *Tnp* gene linked to *lacZ* in pMC1103 is controlled by the repressor substance.

Suppression of the R49 amber mutation in the Tn*3* repressor gene by a bacteriophage carrying an amber suppressor (λsupF, Table 2, line 4) resulted in decreased synthesis of β-galactosidase, providing additional verification that the Tn*3* repressor substance regulates expression of the *Tnp* gene. The degree of suppression of the amber mutation observed in these

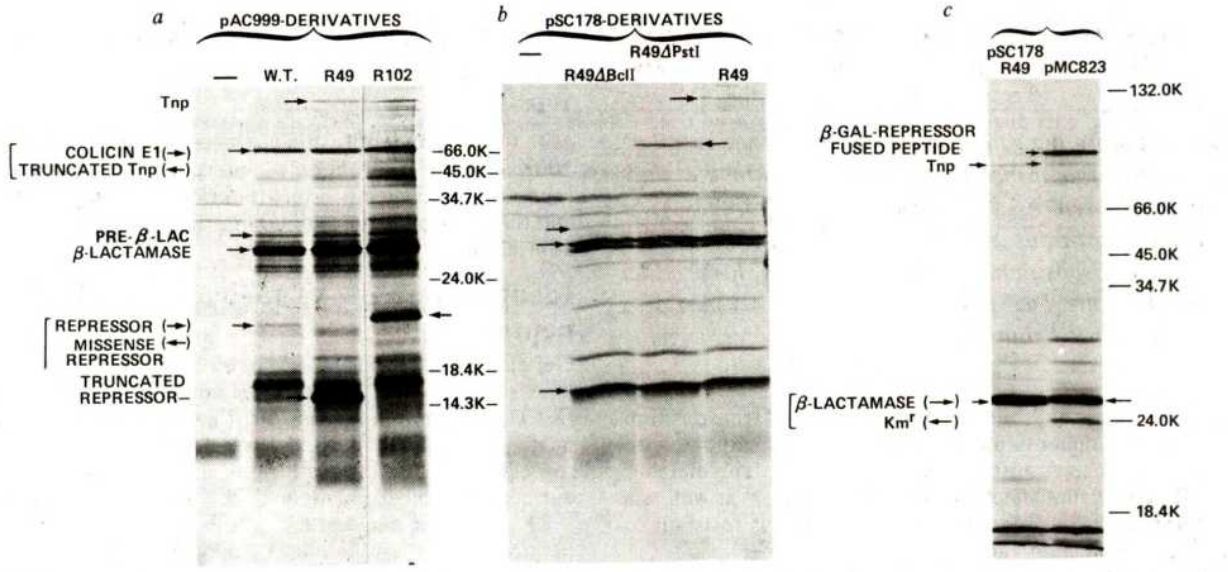

Fig. 1 Autoradiograms showing ^{35}S-labelled polypeptides synthesised by *E. coli* minicells containing plasmids carrying Tn*3* or its mutant derivatives. Media used[32], purification of minicells[23], and labelling[23] and electrophoresis[24] of peptides in polyacrylamide-SDS gels (15%, panels *a* and *b*; 10%, panel *c*) have been described. Molecular weight standards (between panels *a* and *b*; right-side, panel *c*) were lysozyme (14,300), β-lactoglobulin (18,400), trypsinogen (24,000), pepsin (34,700), ovalbumin (45,000), bovine plasma albumin (66,000), and cross-linked bovine plasma albumin (panel *c* only, 132,000). In panel *a* are shown the patterns of peptides from the minicell strain lacking a plasmid (−) and from minicells carrying the pACYC999 (ColE1::Tn*3*) plasmid or its derivatives, containing the R49 or R102 repressor mutations. Arrows in this panel (and in *b* where appropriate) indicate the positions of the 100K peptide encoded by Tn*3* (Tnp), colicin El (→), the 28K β-lactamase protein and its 30K precursor (pre-β-*lac*)[9,28] and the wild-type, nonsense truncated (R49), and missense (R102) Tn*3* repressor peptides. The Tn*3* deletion plasmids pMC1102 (Δ*Bcl*I) and pMC1104 (Δ*Pst*I) (panel *b*) are derivatives of the pMC1097 plasmid, which is a pSC178 (pSC101::Tn*3*) derivative that carries the R49 amber mutation in the Tn3 repressor gene. pMC1102 and pMC1104 were constructed from pMC1097 DNA by removing internal *Bcl*I and *Pst*I endonuclease-generated fragments of Tn*3* (Fig. 2) by digestion with the respective enzymes, ligation[29], transformation[30], and selection for Ap^RTc^R in the χ1488M minicell-producing strain (obtained from Roy Curtiss III; see also ref. 7). Selection for resistance to Ap ensures that the pMC1104 plasmid has lost only the left *Pst*I fragment of Tn*3*. An additional arrow (←) in panel *b* indicates the position of a 66K truncated Tnp peptide synthesised by the pMC1104 (Δ*Pst*I) deletion mutant. Panel *c* shows patterns for the pSC178-R49 (pMC1097) and pMC823 (ref. 7) plasmids. The latter is a derivative of the pSC105::Tn*3* plasmid in which the *lac* genes have been fused to the Tn*3* element such that the 6th amino acid of the Tn*3* repressor is joined to the 21st amino acid of the *lac*Z gene product, resulting in a fused peptide. The kanamycin-resistant pSC105::Tn*3* plasmid was used as a replicon to construct pMC823 (ref. 7). This plasmid was used to provide an additional selective marker, since the β-lactamase gene of Tn*3* and the Tc-resistant gene of pSC101 are both lost by deletion of the *Bam*HI-generated DNA fragment containing the IRb terminus of Tn*3* to yield pMC823. Arrows in panel *c* indicate for pMC823 the location of the β-galactosidase-repressor fused peptide, the kanamycin resistance gene product (←), and the Tnp peptide. The positions of the 100K Tnp peptide and the β-lactamase protein (→) are shown for the pSC178-R49 plasmid.

experiments (30%) is consistent with the previously reported efficiency of amber suppressors (25–65%)[12]. Analogous experiments carried out in minicells (data not shown) demonstrated a 70% reduction in the amount of the 100K Tnp peptide encoded by the pMC823 plasmid (which has deleted the entire repressor gene, see above) when the pACY999 plasmid, which carries a wild-type repressor gene, was placed *in trans*.

The level of expression of the Tnp–lac hybrid peptide encoded by the pMC1103 plasmid was found to be affected by temperature (5,217, 2,895 and 1,766 units of β-galactosidase at 30, 37 and 42 °C, respectively). These observations are consistent with the previously observed effects of temperature on translocation itself[13,14], and suggest that temperature may affect translocation frequency by a mechanism that controls the efficiency of transcription of the *Tnp* gene.

In the course of these experiments, we detected an additional transcriptional start signal on Tn*3* using the pMC945 plasmid (Fig. 2) which was constructed by insertion of the 903 *lac* sequence into the single *Bam*HI site of the transposon; the orientation of the inserted fragment (as determined by gel analysis, unpublished data) suggests that *lac* gene expression encoded by the pMC945 plasmid results from the presence of a transcriptional start signal located towards or past the carboxy-terminal end of the repressor gene and initiating leftward transcription through the repressor gene. We have not characterised this putative promoter further, and do not know whether it has a biologically significant role. No additional Tn*3* peptide assignable to this region has been identified in minicells. The promotor detected by insertion of the same 903 *lac* fusion fragment into the *Bam*HI site in the opposite orientation (that is, the pMC959 plasmid, Fig. 2) accomplishes expression of the Tn*3* repressor gene and is repressible by a wild-type Tn*3* *in trans* as expected (see ref. 7).

Localisation of the regulatory signals for the *Tnp* gene and determination of translational reading frame

The location and direction of reading of the repressor-controlled gene encoding the Tnp peptide suggested that its promoter is located near the promoter for the repressor gene, which is transcribed in the opposite direction. To investigate the genetic control of the *Tnp* gene and to identify more precisely where transcription and translation of this gene begin, we used

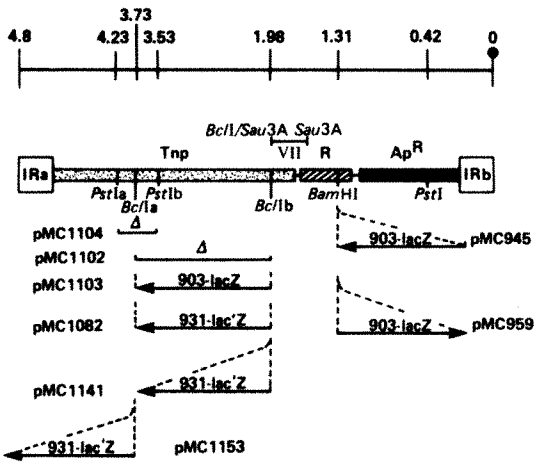

Fig. 2 Schematic map showing structure of *lac* insertions into Tn*3*. *Tnp* is the transposase gene, R the repressor gene, and Ap the β-lactamase gene. IRa and IRb are the inverted repeat termini of Tn*3*. The kilobase co-ordinates of restriction endonuclease cleavage sites discussed in the text are indicated; additional *Sau*3A sites within Tn*3* are not shown. Kilobase coordinates are given relative to the right termini of Tn*3* at IRa. The position of *Sau*3A fragment VII, which contains promoters and translational start signals for genes that are encoded in divergent directions is shown; the left terminus of this fragment is also the $BclI_b$ cleavage site. The segments deleted in the pMC1104 plasmid (Δ*Pst*I) and pMC1102 plasmid (Δ*Bcl*I) are indicated. The 38-base-pair-long inverted repeat termini of Tn*3* (IRa and IRb) are not drawn to scale. The underlying arrows indicate the direction of insertion of 7-kilobase *Bam*HI-generated fragments containing *lacZ* and *lacZ* genes that lack promotors[11]. 903-*lacZ* is missing only the promotor for *lacZ* transcription while *931-lac'Z* lacks both the promotor and a translational start site. The 931-*lac'Z* segment starts with the same *lac* sequence shown in Fig. 3. Insertions of *lac* gene fragments in the *Bam*HI site of Tn*3* were obtained by transformation of *E. coli* strain pMC1050 with ligated mixtures of one of the *lac* fragments and *Bam*HI-cleaved pACYC999 DNA, which contains only one *Bam*HI site in Tn*3* and none within the ColEl segment. *lac* insertions in the *Bcl*I sites were obtained by cloning the *lac* fragments into partially *Bcl*I-cleaved pSC101::Tn*3* R49 DNA (the pMC1097 plasmid) which has two *Bcl*I sites within Tn*3* and none in the pSC101 segment. The *Bam*HI and *Bcl*I enzymes yield identical complementary protruding ends. DNA to be cleaved by *Bcl*I was grown in a *dam*⁻ *dcm*⁻ methylase-deficient strain since methylation of DNA synthesised in *E. coli* K12 precludes *Bcl*I cleavage by the *Bcl*I enzyme.

Table 1 Effect of repressor on synthesis of the Tnp protein

Experiment 1

Plasmids	β-Lactamase (c.p.m.)	Normalisation ratio	Repressor (c.p.m.)	Transposase (c.p.m.)
(1) None	(102)*	—	(56)	(76)
(2) pACYC999 (ColEl::Tn*3* R⁺)	12,880	1.0	383†	105†
(3) pACYC999 R49 (ColE1::Tn*3* R49)	12,440	1.0	23,873†	804†
(4) pACYC999 R67 (ColE1::Tn*3* R67)	14,340	0.9	—	824†
(5) pACYC999 R102 (ColE1::Tn*3* R102)	21,892	0.6	3,760	507†

Experiment 2

Plasmids	Truncated repressor (c.p.m.)	Normalisation ratio	Transposase (c.p.m.)
(6) None	(381)	—	(92)
(7) pACYC999 R49	45,185	1.0	4,623†
(8) pMC1097 (pSC101::Tn*3* R49)	15,966	2.8	1,963†
(9) pMC1104 (pSC101::Tn*3* R49 ΔPst)	9,421	4.8	7,449(t)† (138)
(10) pMC1102 (pSC101::Tn*3* R49 ΔBc1)	9,445	4.8	(74)

The conditions for isolation and purification of chromosomeless minicells[9] of *E. coli* strain χ1488M and for labelling and analysis of protein in acrylamide-SDS gels have been described[7,23,24]. The sections of the gels (shown in Fig. 1) containing the appropriate bands were excised, digested with H_2O_2, treated with catalase, and counted[25]. The counts per minute of peptides of interest were internally normalised to either the β-lactamase band (expt 1) or the R49-amber nonsense repressor band (expt 2) by multiplying the observed counts by the ratio of counts in the internal control bands (normalisation ratio). t = truncated transposase peptide. R67 is another previously described amber nonsense mutation in the Tn*3* repressor gene[7].

* Parentheses indicate control c.p.m. determined for a slice of control gel removed from the same location as the band being analysed.

† Normalised counts.

Table 2 β-Galactosidase synthesis by *Tnp-lac* fusions plasmids

lac fusion plasmid	Plasmid *in trans*	β-Galactosidase (units)	Repression ratio
(1) pMC1103	—	5,300	
(2) pMC1103	pACYC999	1,100	
(3) pMC1103	pACYC999 R49	5,700	5.2 [pACYC999 R49/pACYC999]
(4) pMC1103	λsupF	3,000	1.8 [-/λsupF]
(5) pMC1082	—	130	
(6) pMC934	—	1,200	
(7) pMC934	ColE1	1,000	8.5 [ColE1/pACYC999]
(8) pMC934	pACYC999	120	
(9) pMC995	—	500	
(10) pMC995	ColE1	320	5.0 [ColE1/pACYC999]
(11) pMC995	pACYC999	66	

The structure of most of the pMC series of plasmids is shown in Fig. 2. pMC995 is structurally identical to pMC1082 except that its replicon is pACYC177 (ref. 26) rather than pSC101 (see text). The difference in copy number of the two vectors presumably is responsible for the observed difference in level of β-galactosidase (lines 5 and 9). The pACYC999 plasmid, the R49 amber mutation, the pACYC140 plasmid and the introduction of the λ supF amber suppressor have been described previously[7,26,27]. For β-galactosidase assays, strain MC1050 carrying the plasmids indicated was grown to appropriate cell density in minimal medium at 30 °C and assayed for the enzyme as described elsewhere[12].

lac gene fusions to isolate promoter-containing fragments of Tn*3* that are repressible by a wild-type Tn*3* *in trans*. Since the frequency of transposition and the synthesis of *Tnp* gene product are both regulated by the Tn*3* repressor (refs 5–7 and above), we hypothesised that at least some of the fragments isolated in this way might contain the *Tnp* gene promoter.

These experiments utilised the pMC874 plasmid (Fig. 3), which includes a gene encoding resistance to kanamycin (Km) plus a *lac* gene fragment in which the regulatory region for the *lacZ* gene and the codons for eight amino acids at the amino-terminal end of this gene have been removed and a *Bam*HI cleavage site has been introduced. The segment of *lacZ* that remains determines sufficient primary structure to yield a functional β-galactosidase enzyme, which can be expressed when a DNA fragment carrying both transcriptional and translational start signals is introduced into the *Bam*HI site[11]. In such a case, *lac* gene expression is placed under the control of a promoter, ribosomal binding site, and translational start codon on the inserted fragment and the resulting fusion peptide contains an amino-terminal end encoded by DNA sequences on the fragment.

A *Bam*HI endonuclease-generated fragment (931 *lac*) containing the *lac* gene segment derived from the pMC874 plasmid was introduced into the *BclI*$_b$ site of Tn*3* on pMC1097 as shown in Fig. 2 to yield the pMC1082 plasmid. Since the *Bam*HI and *BclI* endonucleases generate identical 4 base pair-long cohesive termini (that is, GATC), the 931 *lac* fragment can be readily inserted at either of the *BclI* sites identified within the *Tnp* gene or can be substituted for the Tn*3* DNA fragment between *BclI* sites a and b. The resulting constructs bring synthesis of the *lac* gene product under the control of regulatory signals for *Tnp*; β-galactosidase level can then be used as a direct indicator of *Tnp* expression.

As seen in Table 2, β-galactosidase is made by the pMC1082 Tn*3*–*lac* fusion plasmid, indicating that translation (as well as transcription, as noted above) of the *Tnp* gene commences at a location to the right of the *BclI*$_b$ site. A Lac$^+$ phenotype was observed with this plasmid and also with pMC1141, which contains an insertion of the 931 *lac* fusion fragment into the *BclI*$_b$ site of pMC1097 (Fig. 2). Since the reading frame of the DNA segments on both sides of the *Bam*HI/*BclI*$_b$ junction must be the same to yield expression of *lac* in the 931 *lac* fusion, and since the translational reading frame of the *lacZ* gene segment in the fusion is known in relation to its *Bam*HI cleavage site (see Fig. 3) and the *BclI*$_b$ site in the *Tnp* gene (Fig. 4), these results establish directly the reading frame for the *Tnp* gene. It is of some interest that *lac* expression from the pMC1082 fusion plasmid, which utilises both the transcriptional and translational signals of the *Tnp* gene, is less than 3% of the level of *lac* expression from pMC1103—in which the *Tnp* transcriptional promoter is linked to translational control signals of *lac*. This implies that relatively ineffective translation of a messenger RNA species transcribed from an efficient *Tnp* gene promoter is responsible for the observed weak expression of the *lacZ* gene in pMC1082. This interpretation is supported by results that show a markedly increased level of the *Tnp* gene product as a result of mutation within the putative translational control region for the gene (M.J.C., J.C. and S.N.C., unpublished data).

To localise more precisely the transcriptional and translational control region for the *Tnp* gene, we used the pMC874 plasmid to clone and isolate a small fragment of Tn*3* that could initiate Tn*3* -repressible expression of the *lac* gene segment. A plasmid that includes a wild-type Tn*3* element (such as pACYC999, which is ColE1 :: Tn*3*) was cleaved into small pieces using the *Sau*3A endonuclease, which recognises a 4-base pair sequence (GATC) that is a subset of the *Bam*HI recognition sequence[13], and which generates projecting ends identical to those produced by *Bam*HI. *Sau*3A-cleaved pACYC999 plasmid DNA was ligated to the *Bam*HI-digested pMC874 plasmid, and the composite molecules were introduced by transformation into *Escherichia coli* strain MC1050 which carries a *lac* deletion. One per cent of the transformants (transformation frequency 10^5 per μg DNA) showed a Lac$^+$ phenotype on lactose–MacConkey plates containing Km (10 μg ml^{-1}), suggesting that a *Sau*3A-generated DNA fragment(s) carrying transcriptional and translational start signals had been cloned in the appropriate orientation at the *Bam*HI site of pMC874.

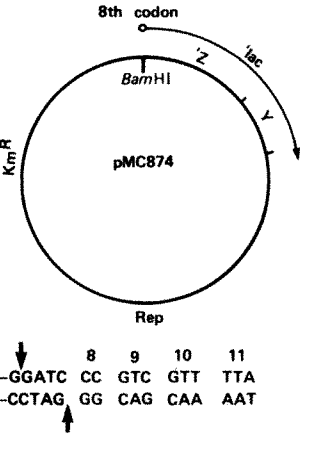

Fig. 3 Simplified map of pMC874 plasmid[11] indicating the position and orientation of the *lacZY* genes and the location of Km^r determinant and replication region (rep). This derivative of the pACYC177 plasmid[26] contains a unique *Bam*HI site, which results in cleavage before the eighth codon of the *lacZ* gene. DNA fragments that contain transcriptional signals and translational start codons yield a Lac$^+$ phenotype when introduced in frame with the *lacZ* gene at the *Bam*HI cleavage site. Addition of exogenously derived amino acids to the β-galactosidase protein does not affect its activity.

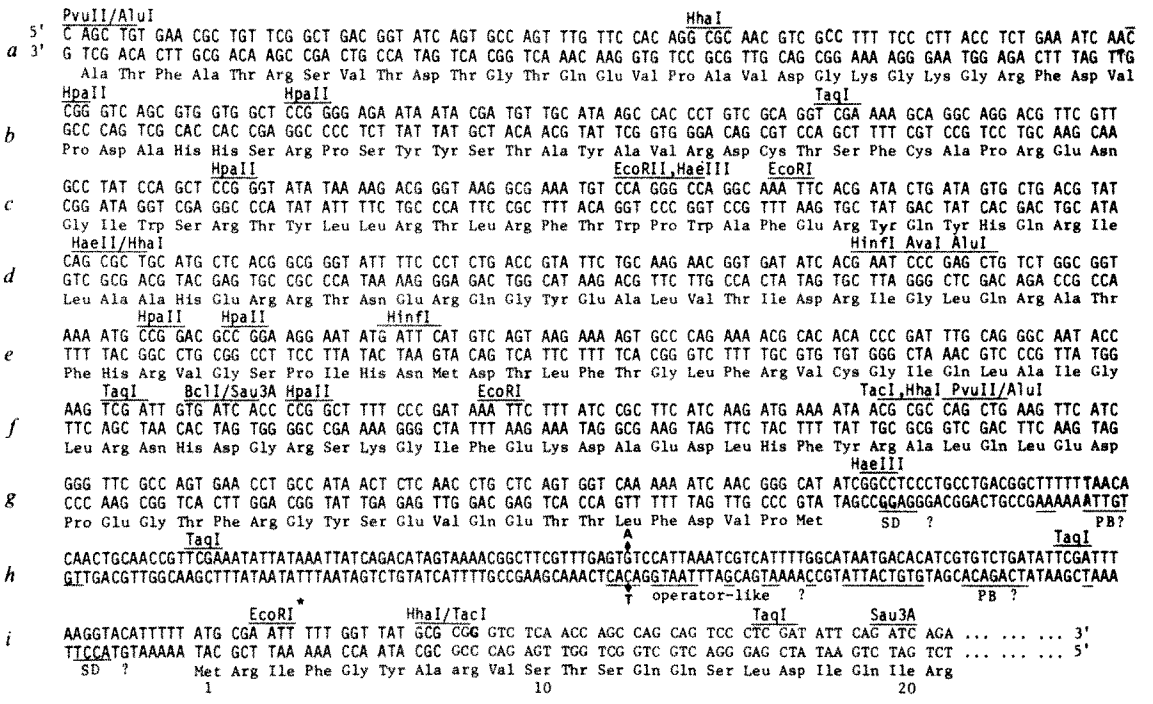

Fig. 4 Partial DNA sequence of the transposase and repressor genes of Tn*3*. The location of the Cis_{10} operator-constitutive mutation (which results in a C → T base change in the DNA strand corresponding to mRNA for the repressor gene)[7] is shown in the operator-like palindromic sequence in panel *h*. Putative Pribnow box[17] (PB) and Shine–Dalgarno[16] (SD) sequences are shown for both the repressor and transposase genes. The translational start site for the repressor protein has previously been shown to be at the methionine codon-labelled amino acid 1 in panel *i*. The translational start site for the transposase gene, which is read in an opposite direction from that of the repressor, is assigned to the methionine codon (labelled as amino acid 1) in panel *g*. It is possible, however, that initiation of the Tnp peptide occurs at another nearby location, as discussed in the text. The positions of some endonuclease cleavage sites are indicated. *Sau*3A fragment VII of Tn*3* is a 359-base pair fragment extending from the *BclI*/*Sau*3A site at the 46th amino acid of the transposase gene (panel *f*) to the 20th amino acid of the repressor gene (panel *i*). The DNA sequence was determined by the Maxam and Gilbert procedure[31] by analysis of multiple fragments within the region shown, and sequences were confirmed from both strands of the duplex DNA. Details of which specific endonuclease-generated fragments were sequenced and the primary sequencing data are available from the authors on request. All fragments were labelled with [γ-^{32}P] ATP (~3,000 Ci mmol^{-1}, ICN) at the 5′ends using bacteriophage T4 polynucleotide kinase.

Twenty-five randomly selected Lac$^+$ colonies were purified by restreaking and examined for the ability of the *lac* gene carried by pMC874 derivatives to be repressed *in trans* by a wild-type Tn*3*; four of these colonies showed repression of Lac$^+$ phenotype *in trans* by a wild-type Tn*3* element carried by either bacteriophage λ or the pSC101 plasmid. The restriction endonuclease cleavage pattern of plasmid DNA from the four repressible Lac$^+$ isolates was compared by electrophoresis in 5% polyacrylamide gels with the pattern seen for the pMC874, ColEl and pACYC999 (ColEl::Tn*3*) plasmids (data not shown). The only cloned fragment detectable in one of the plasmids (pMC934) was a *Sau*3A fragment similar in size to one included within Tn*3*; the other three Lac$^+$ isolates contained plasmids that included this fragment plus additional *Sau*3A fragments derived from Tn*3* or ColEl.

Endonuclease mapping (unpublished data) of the *Sau*3A fragment common to the four repressible Tn*3*–*lac* fusion plasmids (*Sau*3A fragment VII of pACYC999) showed that it was the same Tn*3* fragment that contains the coding sequence for the NH_2-terminal end of the repressor gene and the regulatory region for the gene (Fig. 4; see also ref. 7). The orientation of insertion of the *Sau*3A-generated fragment in two of these clones (including that carrying the pMC934 plasmid) was found to juxtapose the regulatory sequences for the repressor and the β-galactosidase gene of pMC874. Moreover, a nucleotide sequence of undetermined origin and too short to be detected on 5% polyacrylamide gels was present at the *Sau*3A/*Bam*HI junction of pMC934, bringing the translational reading frames of the repressor and β-galactosidase segments of the fused protein into concordance. This finding suggested that the extraneous fragments identified in the other repressible Lac$^+$ isolates might also be accomplishing a frame shift that places *lac* in the same translational reading frame as the repressor.

*Sau*3A fragment VII was purified from pACYC999 plasmid DNA by electrophoresis on 5% polyacrylamide gel and ligated to *Bam*HI-cleaved pMC874 DNA in the absence of detectable extraneous DNA fragments that might shift the translational reading frame. Plasmid DNA from four randomly selected Lac$^+$ repressible clones was examined by gel electrophoresis and in each case was found to contain *Sau*3A fragment VII in an orientation opposite to the orientation observed for pMC934. The plasmid present in one of these clones was designated pMC995. β-Galactosidase encoded by both the pMC934 and the pMC995 plasmids was repressed by a wild-type Tn*3* *in trans* (Table 2, lines 6–11) showing that transcription and translation proceed from *Sau*3A fragment VII in divergent directions and that the divergent promoters are both regulated by the repressor gene product. These findings provide direct evidence for bidirectionality of the genetic unit containing *Tnp* and repressor genes, which was first inferred from polyacrylamide gels of gene products made in minicells. Although other promoter regions within the pACYC999 plasmid have been detected by the use of pMC874 plasmid translational fusions, the two promoters we have identified on the *Sau*3A fragment VII of Tn*3* were the only ones found to be regulated by the repressor.

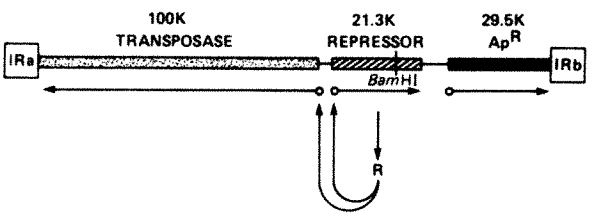

Fig. 5 Schematic diagram showing locations of Tn*3* genes and their regulatory signals. As shown, a 21.3K repressor peptide acts to reduce transcription from the promotors for the transposase and repressor genes, which are bidirectionally expressed.

Nucleotide sequence analysis of the transcriptional and translational control region of the transposase gene

Nucleotide sequence analysis was carried out for the Tn*3* DNA segment encoding the NH_2-terminal portion of the *Tnp* gene product and the regulatory region for this gene (Fig. 4). As indicated above, the 359 base-pair long *Sau*3A fragment VII of the pACYC999 plasmid contains the transcriptional and translational control region, plus the NH_2-terminal sequences for both the repressor and transposase peptides; together these genes appear to constitute a bidirectional genetic unit that regulates transposition of Tn*3*. Amino acids for the Tnp peptide are assigned from the ATG (AUG) codon located to the left of the single *Hae*III site within the intergenic region; no termination codon in the same frame as this ATG was seen throughout the DNA segment we have sequenced (585 base pairs). The presence on the coding strand of a GGAGG putative Shine–Dalgarno ribosomal binding sequence[16] preceding the ATG codon, and a possible Pribnow box[17] for binding of RNA polymerase[18] several nucleotides further towards the 5′ end of the coding strand, is consistent with this assignment. However, another possibility is that initiation of the Tnp peptide occurs at the GTG (GUG) codon that is 33 nucleotides nearer to the 5′ end of the coding strand. This codon, which is known to be capable of initiation of translation[19], is also in the correct reading frame as ascertained by our DNA sequence analysis.

The occurrence, mid-way between the transcriptional start signals for the repressor and *Tnp* gene, of the palindromic sequence proposed by us to be the operator structure[20] for the repressor gene of Tn*3*, raises the possibility that this single operator may control both components of the bidirectional Tn*3* transposition unit. Control of two promoters by a single operator region located between divergent genes has been reported previously for the bacteriophage λ*cI–cro* operon[21].

Overall regulation of the Tn*3* transposition unit

The present results, and those reported earlier[7], provide a structural and functional basis for regulation of the transposition frequency of Tn*3* and also explain the observation that structural integrity of the region to the left of the *Bam*HI site of Tn*3* is required for transposition to occur[2,3,8]. The self-regulated repressor gene is shown here to be part of a repressor-controlled divergent genetic unit (Fig. 5) that includes a gene encoding a large peptide essential for transposition of Tn*3*.

Transposition is thought to be a multi-step process that involves DNA nicking and ligation steps, plus replication-related functions[22]. The large size of the Tnp peptide may reflect an ability to carry out multiple steps in the transposition process.

These studies were supported by grants from the American Cancer Society, the NIH, and the NSF to S.N.C. P.G.L. and M.J.C. are recipients of NIH postdoctoral research fellowships.

The molecular structure of cytochrome c_3 isolated from Desulfovibrio desulfuricans *has been solved on the basis of its crystallographic determination at 2.5 Å resolution and of an essentially complete sequence. The molecule consists of a single polypeptide chain wrapped around a very compact core of four non-parallel haems which present a relatively high degree of exposure to the solvent. Alignment of the amino acid sequences of cytochrome c_3 from several species suggests that the structure reported here is characteristic of the cytochrome c_3 group.*

SULPHATE reducing bacteria of the genus *Desulfovibrio* are characterised by the presence of a specific electron carrier protein which has been called cytochrome c_3 (ref. 1). These proteins have recently been defined as a unique class of haemoproteins which contain four haems per molecular weight of about 13,000, are autoxidisable and bear a negative oxidoreduction potential[2].

With the publication of the amino acid sequences of cytochromes c_3 from three different species of *Desulfovibrio*[3–5], it became clear that in spite of large differences in their amino acid composition cytochromes c_3 constitute an homologous class of proteins characterised by the presence of four haem attachment

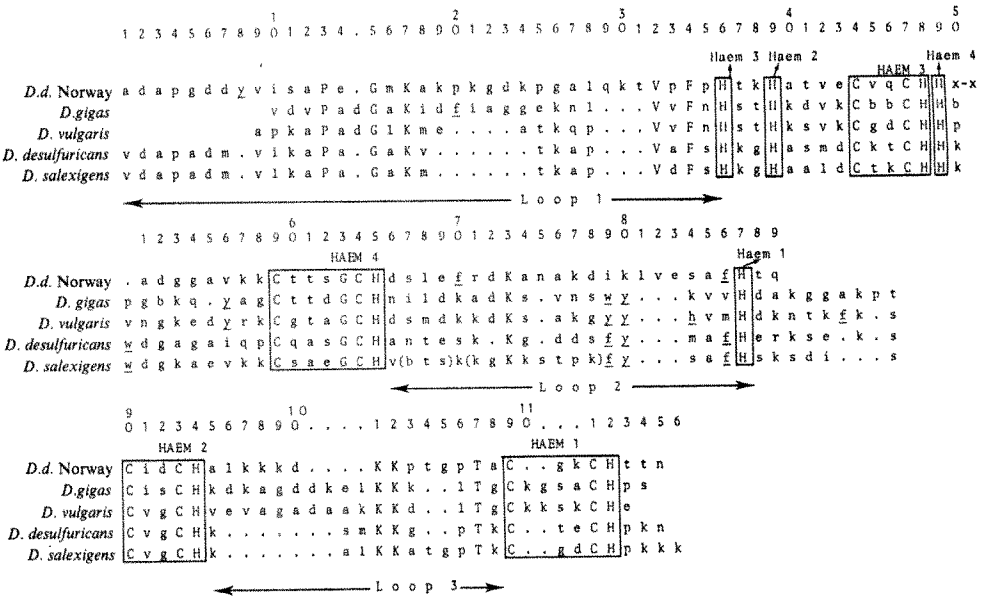

Fig. 1 Sequence homology of cytochromes c_3. The sequences are expressed in the one letter code[27]; *D.d.* Norway is the reference sequence; capitals indicate residues common to each sequence. Haem attachment sites are enclosed in boxes and other aromatic residues are underlined.

sites, that is, -Cys-x-x(x-x)-Cys-His-. The sequence of the cytochrome c_3 from *Desulfovibrio desulfuricans* Strain Norway (*D.d.* Norway) is almost completed and is used in the present three-dimensional study (Fig. 1).

The structural organisation of four porphyrin rings within a relatively short polypeptide chain should be quite remarkable and already extensive EPR[6], NMR[7,8] and Mossbauer[9] studies have been undertaken and led to some important results: (1) the sixth axial haem ligand is a nitrogen atom of a histidine residue, therefore each iron coordination complex in cytochrome c_3 is of bis-histidinyl type; (2) close haem–haem intramolecular interactions are strongly suggested in view of short inter-iron distances (~10 Å); (3) the slow electron exchange observed between haems favours the proposal that these proteins do not act as simple electron conductors but more likely as storage devices for electrons; (4) an outline structure of *D. vulgaris* cytochrome c_3 based on sequence, EPR and NMR studies has been proposed by Dobson *et al.*[8] and will be discussed later.

The physiological electron donor and/or acceptor for cytochrome c_3 is hydrogenase. In *Desulfovibrio* species the presence of cytochrome c_3 is a requirement for the electron transfer to occur in contrast to *Clostridium* species in which this process takes place by direct coupling between hydrogenase and low redox potential proteins such as ferredoxin, flavodoxin and rubredoxin[10]. Insofar as the physiological properties of the *D.d.* Norway cytochrome c_3 are known they deserve a few comments since they differ remarkably from those of cytochrome of *D. gigas* and *D. vulgaris*. In the Norway strain cytochrome c_3 has a sulphur reductase activity[11]. Cytochrome c_3 from *D. vulgaris* also reduces sulphur but its activity is strongly inhibited by hydrogen sulphide, the product of the reaction. Another property of *D.d.* Norway cytochrome c_3 also favours a change in the function of this protein: it couples the reduction of thiosulphate from molecular hydrogen in cell-free extracts whereas *D. gigas* c_3 does not. In this latter organism this function is the property of another cytochrome absent in the Norway strain, containing eight haems per molecular weight of 26,000 and also named c_3 (ref. 12). It is noteworthy that cytochrome c_3 is not the only *c*-type cytochrome in *D.d.* Norway since a monohaem cytochrome $c_{553(550)}$ has recently been purified[13].

The X-ray crystal structures of several monohaem *c*-type cytochromes led to the important conclusions that these molecules appear to have a similar 'cytochrome fold' and to belong to the same evolutionary group, indicating a common origin for electron transport chains in photosynthesis and respiration[14–16]. We present here the first high resolution structure of a multihaem cytochrome in which the complete polypeptide chain around a compact four haem arrangement could be traced throughout.

Experimental methods

Cytochrome c_3 from *D.d.* Norway was crystallised in 50% 2-methyl-2,4-pentanediol at room temperature and at *p*H 7.7. Rod-shaped crystals were obtained in trigonal space group $P3_1$ ($P3_2$) with unit cell parameters $a = b = 43.72$ Å $c = 64.45$ Å (ref. 17).

Full details of the structural analysis will be reported elsewhere but the strategy may briefly be outlined here. Three mercury derivatives were used, all prepared by soaking native crystals in appropriate solutions ($HgCl_2$, $Hg(SCN)_2$, ethylmercuriphosphate). Replicated data including Bijvoet reflections were collected on a CAD-4 Enraf-Nonius diffractometer with Ni-filtered CuK α radiation and an ω-scan procedure. The single site (A) of derivative $HgCl_2$ was found to be common to the three derivatives. Heavy atom parameters were refined by the F_{HLE} procedure of Dodson and Vijayan[18], with empirically determined values of the real/imaginary scattering ratio[19]. Before, the final phase calculation combining isomorphous and anomalous measurements, accurate haem-iron coordinates were required, as the anomalous scattering from native iron atoms is far from being negligible. Native protein phases were first calculated from isomorphous data alone[20]. The mean figure of merit for the 4,400 reflections at 2.5 Å resolution was relatively low; 0.66. At this point the electron-density map allowed a straightforward identification of the molecular boundary and of four regions of significantly higher density which obviously could be attributed to the four haem groups of the molecule. Moreover the iron atom parameters could be refined properly by a least-squares procedure using the observed native anomalous differences, in a way similar to that described for cytochrome b_5 (ref. 21). With accurate iron coordinates it was then possible to calculate a second set of 'best' phases based on both isomorphous and anomalous contributions. This led to a mean figure of merit of 0.76 falling off from 0.82 at 6 Å resolution to 0.64 at 2.5 Å resolution. The high quality of the electron-density map calculated with these improved phases can be judged from Fig. 2.

Description of the molecule

The present model is based on the polypeptide chain continuity observed on the electron density map drawn at the scale of 0.4 Å cm^{-1} and on sequence information. From this 'mini' map the high contrast between protein and solvent regions allows an easy separation between molecules. Cytochrome c_3 appears as a

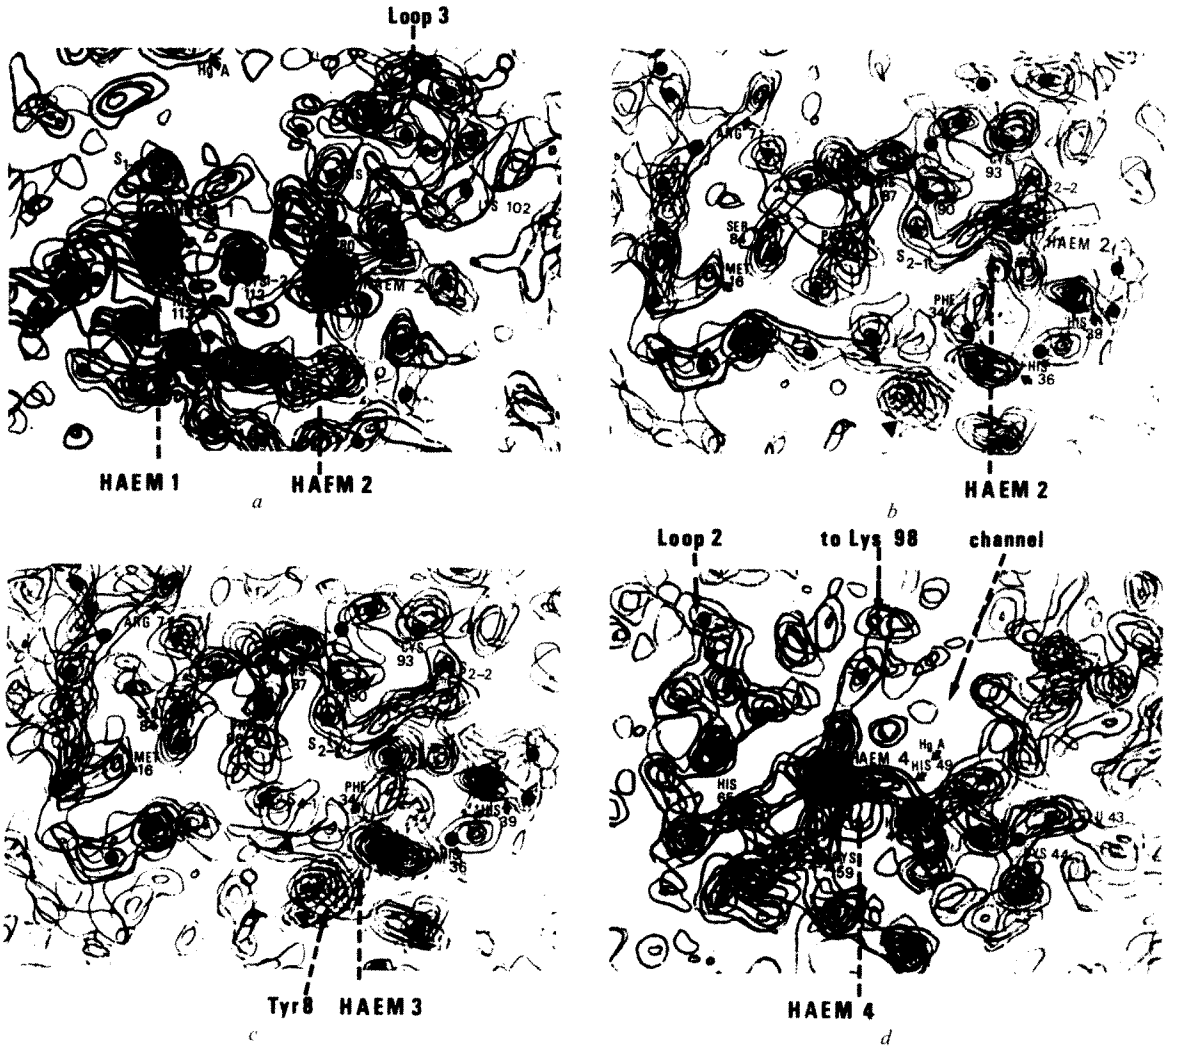

Fig. 2 The electron density map in the different haem regions. The sections are perpendicular to the three-fold axis. *a*, Haem 1 and the top of haem 2. Note the propionates of haem 2 and the loop 3; *b*, Haem 2 with His 39, Cys 90 and Cys 93; *c*, Haem 3 nearly parallel to the plane of the section. Tyr 8 is hydrogen bonded to one of its propionic acid groups; *d*, Haem 4 and the two consecutive His 48 and His 49. ○, Haem centre; ★, sulphur atom of cystein residue; ●, α-carbon; ►, carboxylate of propionic acid.

bean-shaped molecule of overall dimensions 45 × 28 × 32 Å the last figure corresponding to the three-fold axis direction. The course of the main chain could be traced entirely and the orientation of the four porphyrin rings as well as the haem binding groups are clearly visible.

The folding of the α-carbon backbone is shown diagrammatically in Figs. 3 and 4 together with the haem arrangement. Due to lack of overlap information a very small part of the sequence after His 49 has not yet been identified. Indeed the electron-density map clearly indicates the presence of one or two residues between His 49 and the next Ala and we decided to include one amino acid presently not identified and labelled X–X in position 50. A definite answer must await the final sequence data and the optimum fitting of the molecule in the Richards box. Many side chains are already identified on the mini map (Fig. 2), and are in excellent agreement with the sequence. In brief the chain consists (Figs 3 and 4) of three external loops and interconnecting haem segments, and adopts a right-handed helical conformation around residues 86–100. This helical segment runs roughly parallel to the porphyrin plane of haem 1 and contains two histidines, at residues 87 and 94, respectively linked to haems 1 and 2. At the junction of loops 2 and 3 the molecule is bent into a V-form giving rise to a deep depression. Both *N* and *C* terminals are clearly visible and lie on the surface of the molecule. Most of the hydrophilic amino acids are located on these external loops. Among the 17 lysines and the 10 aspartic acids of the molecule, 13 and 8 respectively are found on these loops. For instance loop 3 contains the remarkable segment Lys 97-Lys-Asp-Lys-Lys 102.

Haem core

The most remarkable feature of the c_3 structure is the compact organisation of the four haems within the molecule. These lie near the surface of the protein, haems 2 and 4 sharing the same long groove dividing the molecule in two halves with one haem moiety in each. The short iron-to-iron distances which range from 10.9 Å (Fe2–Fe3) to 17.3 Å (Fe1–Fe3) reflect the close packing of the four non-parallel porphyrin rings as indicated on Figs. 3 and 4. Haems 1 and 3 are nearly parallel and roughly perpendicular to porphyrin rings 2 and 4, a spatial arrangement which does not reveal any internal symmetry.

The electron density in the neighbourhood of the four redox centres is shown on Fig. 2 where some essential features can be observed. First of all, each haem is linked, as in cytochrome *c*, to the apoprotein by two thioether bonds involving well resolved cysteines. The fifth and sixth ligands of each iron atom are provided by histidyl residues, as in cytochrome b_5. This is in agreement with previous NMR studies[7,8], ruling out Met and Lys as possible axial haem ligands. Indeed the sole methionine (Met 16) clearly visible on Fig. 2*b* and *c* is definitely not bound

Table 1 Residues close to the various haems

Haem 1	Haem 2	Haem 3	Haem 4
Val 32	Val 32, 42	Val 42, 56	x–x 50
Leu 28	Gly 105	Ala 3	Ala 85
Ala 27	Pro 33, 35	Pro 4	Gln 89
Phe 86	Pro 103, 106	His 39	Phe 86
Thr 31, 107	Phe 34	Phe 34	Lys 57, 80
Ser 84	Thr 104	Tyr 8	
	Lys 38, 97	Lys 58	

to any haem. The two consecutive histidines (His 48, 49), a highly conserved feature of all known c_3 sequences, connect directly the iron atoms 3 and 4 which correspond to the less and the most accessible haems respectively. It is to be noted that each haem group is peculiar in terms of environment and solvent exposure. Residues in the vicinity of the different redox centres are indicated in Table 1. The propionic groups located on the electron density map reflect also the various haem exposures. For haems 2 and 4, which lie in the groove largely open to the external medium, the propionates extend to the solvent whereas for haem 3 they point to the interior of the molecule: one forms a hydrogen bond with the well resolved Tyr 8 (Fig. 2*c*) and the second is also probably hydrogen bonded to Lys 58. Haem 1 seems to present an intermediary situation as it is partly covered by loop 1 and the *C*-terminal region. One of its propionic acids points towards loop 1 and is probably hydrogen bonded whereas the second appears free in the solvent. At this point some interesting intermolecular contacts are observed. One of the propionic groups of haem 4 appears to be hydrogen bonded to Lys 98 of a neighbouring molecule. This haem also faces a channel of about 7 Å diameter running throughout the crystal and providing easy access to His 49, the common binding site (A) for the three mercury derivatives (Fig. 2*d*).

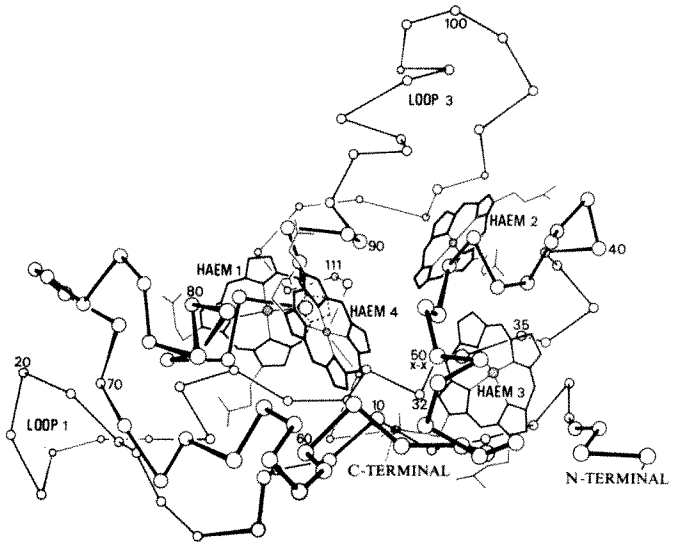

Fig. 3 A drawing of the main polypeptide chain and of the haem arrangement in cytochrome c_3. Haem numbering is arbitrary: when looking along the three-fold axis one goes from haem 1 to haem 4 which are lying respectively near the bottom and the top of the molecule. The view is from the three-fold axis which is perpendicular to the plane of the paper. The α-carbon positions were derived from the mini map and are represented by circles whose sizes indicate their relative depth. Coordinates of haem atoms and haem ligands were measured from a Kendrew wire model built in a Richards box. Inter-iron distances are: Fe1–Fe2 = 12.7 Å; Fe1–Fe3 = 17.3 Å; Fe1–Fe4 = 16.3 Å; Fe2–Fe3 = 10.9 Å; Fe2–Fe4 = 16.8 Å; Fe3–Fe4 = 12.8 Å.

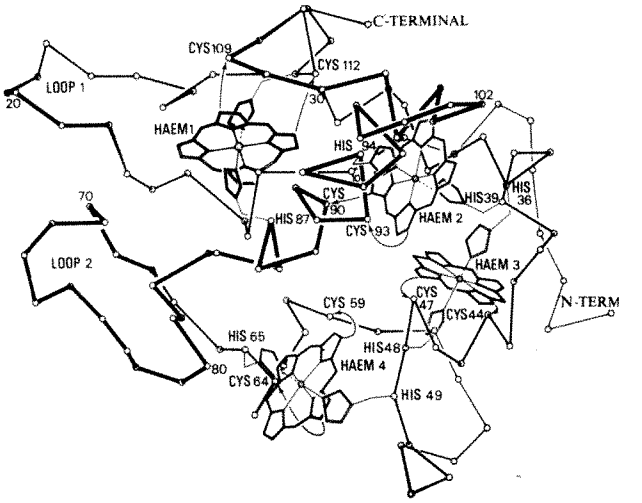

Fig. 4 The main polypeptide chain and the haem arrangement, the direction of view being approximately parallel to the a axis. Angles between porphyrin rings are 85° for haems 3–2, 80° for haems 3–4, 90° for haems 1–2, and 60° for haems 1–4. The shortest inter-haem distances (~5 Å) involving pyrrole rings are found between haems 1 and 2 and haems 2 and 3.

A detailed description of the haem environments, which should help to elucidate the intriguing problem of the haem-haem interactions, will be deferred until the completion of the model (2 cm $Å^{-1}$).

Discussion

The cytochromes c_3 of various species present quite different biochemical behaviours which could imply some changes in their three-dimensional structure, so the question arises as to whether the structure of *D.d.* Norway cytochrome c_3 reflects that of the other cytochromes c_3. Comparison of primary structure of several cytochromes c_3 shows a relatively low degree of homology: among the five available sequences only 25% of the total residues remain invariant, such a variability being uncommon in the *c*-type cytochrome family. A possible alignment of these sequences is proposed in Fig. 1 with the *D.d.* Norway structure as reference. This alignment is based on the haem binding groups, that is the four invariant Cys—Cys-His and the four invariant histidyl residues. It is clear that most of the changes appear in the external loops and could be accommodated without disturbing the haem core. However an important modification concerns the region between His 87 and Cys 90. Examination of the reference structure suggests that this short (two amino acids) chain in *D.d.* Norway can be replaced by a longer (six to nine amino acids) external loop, and such an insertion does not necessarily imply a change in the orientation of the proximate haem 2. At present there are no structural arguments to support a different arrangement of the haem core in the cytochromes c_3.

More subtle differences must be responsible for differentiated reactivities of cytochromes c_3, for instance the high variability of aromatic side chains which is not encountered in the cytochrome *c* family. Striking evidences are shown (Fig. 1). Tyr 8 which is hydrogen bonded to the propionic group of haem 3 is specific for *D.d.* Norway which in contrast does not contain the tyrosines and tryptophans found in the other cytochromes in loop 2 or between haems 3 and 4. Phe 34 which is located between haems 2 and 3 in the *D.d.* Norway structure (Figs. 2*b* and *c*) is invariant in the five molecules suggesting that this residue is probably important for the electron transfer mechanism. On the other hand Phe 86, between haems 1 and 4 (Fig. 2*c*), is only found in two cytochromes. Extra aromatic residues are underlined in Fig. 1.

Despite these local variations it is likely that the three-dimensional structure reported here is representative of the

cytochrome c_3 molecule generally. In this respect the model proposed by Dobson *et al.* for *D. vulgaris* is in conflict with the actual structure. There are at least two major differences. First, the short chain segments between haems 2 and 3 and between haems 3 and 4 do not require the parallelism between the porphyrin rings but, on the contrary, haem 3 is roughly perpendicular to haem 2 and haem 4. Second, the folding suggested previously by these authors was based on the idea that the polypeptide chain is wrapped around an inner haem region. This is not true in our model with regard to the external loops and the exposure of the haem moieties as described above. In fact it would be interesting to refine the interpretation of the NMR and EPR data on the basis of our three-dimensional model. Future work should also elucidate the dependence of the redox potential on the exposure of each haem as already established for the cytochrome *c* family[22]. It is likely that such a correlation will hold for the cytochromes c_3. As mentioned above each haem obviously has a different exposure to solvent and consequently should present a distinct reduction potential. Indeed several midpoint potentials have been measured either by EPR (ref. 6) or by differential pulse polarography[23] for different cytochromes c_3. The lowest value $E_0' = -340$ mV for *D.d.* Norway should be assigned to the most accessible haems in the structure, namely haem 2 or 4. Such low potentials are not detected in the three-haem cytochrome c_7 from the sulphur-reducing anaerobic bacteria *Desulforomonas acetoxidans*, $E_0' \simeq -200$ mV. It is noteworthy that sequence comparisons show that this cytochrome c_7 can be derived from the c_3 molecule by deletion of a peptide including the binding sites of haem 4. In order to correlate these observations it will be interesting to know the three-dimensional structure of cytochrome c_7 which is now being studied in our laboratory[24].

Recently the interest in a detailed study of cytochrome c_3 from *D.d.* Norway has increased as it has been demonstrated that this protein acts as a very efficient electron mediator in accepting electrons from chloroplasts for the photoproduction of hydrogen from water[25]. In this connection the cluster of four cytochromes *c* described as the reaction centre at the membranes of the red photosynthetic bacteria *Chromatium vinosum*[26] shows an intriguing similarity with the haem core of cytochrome c_3. It is tempting to speculate that such a close proximity between the haems (8–10 Å in *C. vinosum*, as in cytochrome c_3) is an essential arrangement for electron exchange between chloroplast membrane, cytochrome c_3 and hydrogenase.

We thank CNRS and DGRST for financial support.

The IR energy distribution of SS433

C. G. Wynn-Williams & E. E. Becklin

Institute for Astronomy, University of Hawaii, 2680 Woodlawn Drive, Honolulu, Hawaii 96822

SS433 is an extraordinary emission-line object showing periodically varying velocities of up to 50,000 km s^{-1} (refs 1, 2). It is also a variable radio source[3,4] and an X-ray source[5]. Infrared observations of SS433 in the 1–4 μm range have been reported elsewhere[6–10]. The data that we present here include observations at 1–10 μm and indicate first that there are substantial infrared colour variations from night to night and second that there is a sharp long-wavelength cutoff in the IR energy distribution, which was not seen in the earlier, more limited data. The discovery of this cutoff allows the diameter and electron density of the emitting region to be estimated.

Photometric measurements were made on the nights of 29, 30 and 31 May 1979 UT, using the University of Hawaii 2.2-m telescope on Mauna Kea. The 1.2–4.8 μm observations employed an InSb detector and a 6 arc s diaphragm while the broadband 8–13 μm observations used a gallium-doped germanium bolometer and a 6 arc s diaphragm. On each night all the observations were completed within 20 min of the mean time given in Fig. 1, except that the 10 μm observation on the 29 May was made about 2.5 h earlier than the time quoted.

Figure 1 shows that between 1.2 and 4.8 μm substantial night-to-night variations exist with a suggestion that the variations are stronger at longer wavelengths. Unfortunately, no 10 μm data are available for 31 May, but a later observation by Becklin and Telesco, made during the commissioning of the 3.0-m NASA IR Telescope Facility on 1979 June 14.4 gave a 10 μm flux density of $\log S_\nu = -26.82 \pm 0.04$ a factor of 30% less than that observed 15 days earlier. At the same time C. Lonsdale and H. M. Dyck (personal communication) measured a 2.2-μm flux density of $\log S_\nu = -26.54 \pm 0.04$, a value lower than earlier measurements. The IR night-to-night variations of both flux density and colour therefore seem to be substantially larger than those reported in any other wavelength range.

The proposal by Giles *et al.*[9] that the IR emission from SS433 is due to reddened free–free emission from an ionised plasma provides a natural explanation for the shape of the energy

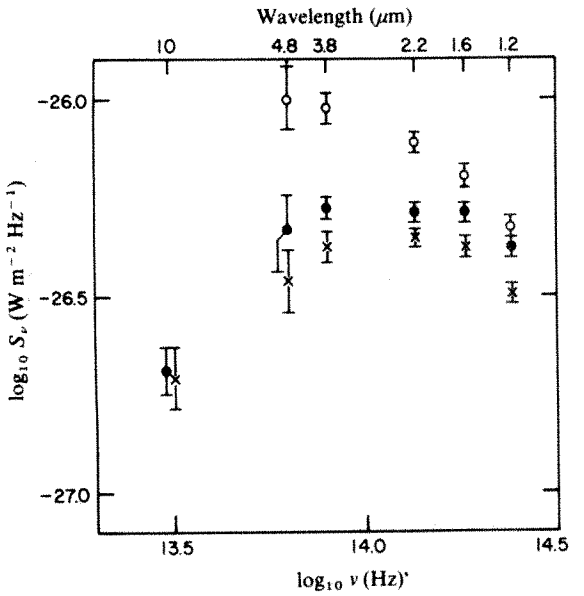

Fig. 1 The IR energy distribution of SS433 on: ●, 29.64 May 1979 UT; ×, 30.51 May 1979 UT; ○, 31.60 May 1979 UT.

distribution shown in Fig. 1, in that the decrease in flux density at wavelengths longward of 5 μm can be attributed to self-absorption. Although it is probable that the standard relationships for H II regions (see ref. 11) are inaccurate at the high column densities encountered in SS433, we may make estimates of the physical parameters of its emitting regions by assuming an electron temperature of 10^4 K and normal recombination theory. From the flux density (0.5 Jy) and the wavelength at the turnover frequency (5 μm) we can derive an angular diameter of order 2×10^{-4} arc s and an emission measure ($\int N_e^2\,dl$) of the order of 10^{17} pc cm^{-6}. If a distance of 3.5 kpc is assumed[1] we estimate a physical size for the emitting region of order 1 AU, an electron density of the order of 10^{11} cm^{-3} and a photoionisation rate of 10^{48} s^{-1}, a value that is similar to that of a late O type star. The size derived here is comfortably smaller than any upper limits implied by the observed variability of the source, while the electron density is high enough to account for the weakness of the forbidden lines in the optical spectrum[1]. The mass of ionised gas, assumed uniform density, is of the order of $10^{-7}M_\odot$.

If the IR radiation arises from free–free emission then a possible explanation for the fact that the variability is greater at longer wavelengths suggests itself. If an H II region is ionisation bounded its optically thin flux density is dependent on the rate of production of ionising photons, but almost independent of the geometry and electron density. At longer wavelengths, however, where self-absorption exists along at least some lines of sight the flux density is much more sensitive to changes in geometry, viewing angle and electron density. Further studies of the time variations of the IR energy distribution of SS433 may therefore help to determine the shape and the properties of its emitting region.

We thank Carol Lonsdale, Mel Dyck and Charlie Telesco for observations. This work was supported by NSF grant AST-7826028 and NASA grant NASW 3159.

Magnetic field of Jupiter and the volcanism and rotation of the Galilean satellites

E. M. Drobyshevski

A. F. Ioffe Physical-Technical Institute, Academy of Sciences of the USSR, 194021 Leningrad K-21, USSR

The discovery by Voyager 1 of several active volcanoes on Io[1,2] opens up a new approach to problems such as the nature and consequences of volcanism on the celestial bodies. In the past 50 yr only Vsekhsviatsky has actively considered modern volcanism on planets, in particular on Moon-like bodies[3,4]. He proceeded from the concept of eruptive origin of comets, however, and did not suggest a physical mechanism to explain the volcanic activity he had postulated. The absence of modern volcanism on the Moon and Mars was against Vsekhsviatsky's ideas and few people considered them seriously, especially in connection with the possible volcanic ejection of icy blocks. Progress was made by Peale *et al.*[5] who predicted the existence of the volcanoes just before they were discovered, and suggested a physical mechanism for the volcanism on Io. They suggested that the tidal dissipation caused by the orbit eccentricity could produce a power $W_{tid}\approx1.6\times10^{12}$ W in Io and 8×10^{10} W in Europa. If the satellites are nonhomogeneous and have a molten interior, the energy release can increase several times. Peal *et al.* estimated the thickness of Io's solid crust as only 18 km. However, "how can Io's south polar region support what appear to be towering mountains? (ref. 6)". (The typical relief is ~10km here[2]). Also, the lack of a detectable intrinsic magnetic field of Io[8] does not favour a fully molten interior. I have previously pointed out that Io's and Europa's orbiting in the strong magnetic field of Jupiter may cause their volcanic activity[7] and this can be confirmed by simple calculations[8,9]. Here I shall estimate the energetics in more detail and discuss some peculiarities of the volcanism itself and consequences of the electromagnetic action mainly on the rocky satellites (the 'icy' volcanism will be considered elsewhere).

Most of the outer planets' satellites are located in the planetary magnetospheres. Io is unique: its interaction with the magnetosphere leads to radiation of ~10^8 W in the decametric band[10]. The radiation is believed to be caused by unipolar generation of the electric current due to Io's movement across the jovian magnetic field[10–12]. The current flows from Io in Jupiter's plasmasphere along the magnetic force tubes down to the highest, weakly conducting ionospheric layers of the jovian atmosphere, just where the radiation is generated. The energy released by Io's interaction with Jupiter's field, has been predicted as, or even more than, 10^{15}–10^{16} W but from estimations of the upper limit of Io's secular acceleration it seems that at present it cannot exceed 10^{14} W (see ref. 10). A more moderate value follows from the consideration that a current generated by the movement of a body across a magnetic field will hardly exceed the current $I_{max}=2\pi BR_s/\mu_0$, whose own magnetic field is equal to the initial field[13].

Table 1 presents the satellites' parameters: D, their distances to the centre of Jupiter; R_s, their radii; M_s, their masses; B, the magnetic field; $\Delta U=2R_sv_{rel}B$, the generated potential difference; I_{max}; $W_{max}=\Delta UI_{max}$ and power W_{rad} supplied by radioactive fission on the assumption of the chondritic composition (5×10^{-12} W kg^{-1}); the rocky cores of Ganymede and Callisto are assumed to be ~1/3 of their mass. For Callisto $W_{max}\ll W_{rad}$, for Ganymede $W_{max}\lesssim W_{rad}$, for Europa $W_{max}\gtrsim W_{rad}$, but for Io and Amalthea $W_{max}\gg W_{rad}$. Note also that $W_{max}>W_{tid}$, although they have the same order of magnitude. The relation between W_{max} and W_{rad} suggest the existence of highly active volcanism on Io and, probably, on Europa.

Callisto	18.8	2420	1.074	0.00023	35	0.3	0.01	0.18	8.9×10^{14}	1.07
Amalthio	1.81	1820	0.891	0.26	500	228.0	114.00	0.45	3.4×10^9	0.08

When estimating Io's radio-wave generation, most of the energy is believed to release in the jovian ionosphere as its resistance is larger compared with Io's integral resistance[12]. Apparently there has not been any estimation of the energy input in Io itself. Note, however, that all available estimations of any interaction parameters of Ioian and jovian field are ambiguous and unreliable[10]. The current values under consideration (restricted by the conductivity of the jovian atmosphere) greatly exceed 10^5 A (ref. 14): for instance, $I = 5\times10^6$ A (ref. 15), up to $I = I_{max}$ and even sometimes considerably higher than I_{max} ($I = 2.5\times10^8$ A follows from $W = 10^{14}$ W). Note that the current is limited by conductivity only at $I < I_{max}$. Also, even if the conductivity is large, I remains nearly equal to I_{max} (ref. 13). Thus, one can take $I \approx I_{max}$ as a characteristic value, which is confirmed by the direct measurement by Voyager[8] of the oppositely directed currents, flowing along one wing of Io-flux tube. The current was estimated as 4.8×10^6 A, hence the total current through Io's body may be as high as, or even more than, 9.6×10^6 A; thus it approaches the value of I_{max} (the currents in the opposite wings of the tube may not be equal and their strength may vary considerably with time[14]). The above choice is also based on the consideration that when the current flows through a gas producing an additional ionisation, and when it flows through solid dielectrics or semiconductors, heating them and ultimately causing thermal breakdown, the volt–current characteristics have a negative slope and the current stabilisation is achieved by other means such as a ballast resistance or, as in this case, by the condition $I \lesssim I_{max}$. Sometimes, an opinion is expressed about the small conductance of Io[16,17] based on the low conductivity of the outermost layers of the Moon with thickness $\lesssim 1$ km, and then it is concluded that the current closes not through Io itself, but through its ionosphere. Clearly, however, any tenuous ionosphere should be momentarily stripped off by the Ampere forces if the magnetic field slips freely relative to nonconducting satellite, but it may exist if the current penetrates the satellite and the field is frozen somehow in its body. Voyager observations[18] reveal numerous warm surface spots on Io, the temperature of which are 200–290 K and maybe even higher. These spots could be entrances for the electric current in the satellite's body through the thin outermost layer. Very crude estimations of the rocky satellite resistance can then be made using available data for the Moon[19]. (The conductivity σ of dirty ices from which the icy satellite crust is formed is higher compared with rocks, about 10^{-4} S, ref. 20). The main input in the resistance comes from the outer 175 km; here $\sigma = 10^{-6}$ S. Then the column with base 1 m^2 has resistance $\sim 2\times10^{11}\ \Omega$, and all the satellite body $\sim 2\times2\times10^{11}/\pi R_s^2\ \Omega$. It gives for Io, 0.04 Ω; for Europa, 0.06 Ω, which is close to values needed for $I = I_{max}$. Thus W_{max} is the right order of magnitude for the additional energy input in the satellite body. In fact, the resistance will be somewhat lower: in the heated satellites the thickness of the low-conductivity crust is smaller and, due to the exponential dependence of conductivity on temperature, the current in the crust will be localised in some separate overheated channels (by analogy to the thermal electric breakdown of dielectrics[21]). In this way one can imagine how the aforementioned surface warm spots are created. It is in these channels that the main energy will be released and hence they will act as natural centres of volcanism. Owing to such 'high quality' input of energy, the volcanoes should appear even at $W_{max} < W_{rad}$. The present mechanism of the volcanic activity excitation has advantages over the tidal mechanism where the main energy is released in the centre of a satellite and at high latitudes[22].

The slow non-synchronous rotation of the satellites (see below) and the maximum electrical field created between two diametrically opposite points mean that the volcanic channels have to be localised primarily in the low and middle latitudes. And indeed, all the known volcanoes and warm spots are at latitudes $\lesssim 30°$ (refs 2, 18). This new type of volcanism indicates that a new type of convection predominates in the crust: for example, the overflowing onto the surface lavas hardens; the crust sinks due to the additional load and its lowest layer melts and then it flows up-wards through volcanoes. The present rate of Io's resurfacing due to volcanic rocky deposits may be 1 mm or more per year[23]. So during 4,000 Myr all the satellite matter should make more than one convective cycle. This convection does not exclude the global convection, when because excess energy is liberated in the low latitudes the surface matter shifts to the poles (in the case of the tidal mechanism, in the opposite direction). Modern conceptions on the Earth's tectonism, suggest that the collision of the surface plates near the poles give rise to mountains. The towering mountains in the polar regions (see above) do exist.

The comparison of W_{max} with W_{rad} for galilean satellites suggests that all of them had initially large amounts of ice but the inner satellites received so much excess energy that the ice was lost.

Intensive explosions from Io's volcanoes accelerating stones up to, and more than 1 km s^{-1} imply the Plinian type of eruption and indicate that a considerable amount of volatiles exist inside Io, contrary to the ancient lunar volcanism which was volatile-poor and so developed mainly basaltic floods[24]. To eject bombs at a velocity 0.5 km s^{-1} the volcanic activity products must contain on the average ~10% gases by weight[25]. An estimated oxygen concentration in Io's plasma torus seems to be much more than the sulphur concentration[26], so the main gas component ejected is probably not SO_2, which aerodynamically is not the best driving medium, but water, as in the Earth volcanoes (so it would be worth attempting to find H_2O and OH in the torus and, essentially, in volcano plumes). Practically all ejected gases escape from Io. Taking into account the present rocky deposition rate 1 mm yr^{-1} (density $\rho = 3$ g cm^{-3}), one should obtain the ice layer ($\rho = 1$ g cm^{-3}) lost during 4,000 Myr as thick as ~1,000 km. Thus it seems reasonable to regard the ancient Io as a Ganymede-like icy body, and its modern rocky volcanic face as a recent acquisition.

Table 1 presents data for Amalthea and 'Amalthio' (an imaginary satellite having Io's parameters but located on Amalthea's orbit). Amalthea's orbit is interesting for three reasons: (1) it is very close to the Roche limit of Jupiter, (2) it practically coincides with the orbit where the value of $W_{max} (\gg W_{rad})$ becomes greatest, and (3) it lies well inside $4–5R_J \approx$ the radius of proto-Jupiter when it set into hydrostatic equilibrium after its rapid collapse caused by the molecular hydrogen dissociation[27] (here proto-Jupiter became sufficiently dense compared with the previous stage when it filled its critical Roche lobe, $R \approx 500R_J$ ref. 28). It would be natural to assume that five, not four, 'galilean' satellites existed initially, but Amalthio has been literally incinerated by Jupiter-Thunderer—by the unipolar electric currents (even now Amalthea is warmer than was expected[18]) and by the hypersonic and radiative ablation. It is difficult to elucidate the relative role of these factors in the

formation of the present Amalthea. It must be surely a remnant of a dense metallic core of Amalthio, strongly elongated by the ablation and bearing traces of the latter. But at some stage, matter could be dispersed by volcanic eruptions. As in the volcanism type under consideration the energy is released directly in the volcano throat, its transformation into the energy of eruptions must have a great efficiency, up to a few per cent. The energy of Amalthio's matter dispersion into space is $\sim GM_s^2/R_s = 3\times10^{29}$ J, so at the energy input $W_{max}\approx10^{14}$ W it takes a few thousand Myr to disintegrate the satellite. In reality, the convection and probably the rotation of young Jupiter were much more intensive[29], so that its past magnetic field was certainly far stronger than at present. $W_{max}\propto B^2$ and the duration of transformation of Amalthio in Amalthea could be below 1,000 Myr. Some of Amalthio's fragments probably created the inner ring around Jupiter.

The idea of the five large satellites and their initial abundance of ice contradicts somewhat the commonly accepted 'micronebular' hypothesis of satellite condensation in the gaseous disk which surrounded hot proto-Jupiter[29], but it accords with my cosmogonical conception which considers the birth of the Solar System as a limiting case of a close binary star origin[30]. The main planetary population of our system consists of Moon-like bodies[28]. They were accreting inside proto-Jupiter filling its critical Roche lobe, in the vicinity of the first lagrangian point, when proto-Jupiter's matter was overflowing onto the Sun, and they were lost one-by-one owing to a rapid decreasing of proto-Jupiter's mass. When the outflowing was completed by cooling the vast and rarefied proto-Jupiter, the last moons (having the great ice abundance) were not able to free themselves and so remained in Jupiter's power as the galilean satellites.

The electric current flows through the satellites across the magnetic field, supplying them with an excess angular orbital momentum[12]. The orbital momentum doubles in

$$\Delta t \approx M_s v_{orb} D/2I_{max}BR_sD = 1.3\times10^{-12}v_{orb}\rho_sR_s/B^2\ \text{yr} \quad (1)$$

This time is small for little Amalthea (Table 1) and its existence on this orbit, so close to the synchronous one ($D_{syn}=1.6\times10^5$ km), would be stranger had it not been a much larger Amalthea in the past. (Amalthea's behaviour may be strongly modified by its own magnetic field of a ferromagnetic nature.)

The nonhomogeneity of the Ampere force $I\times B$ causes the axial rotation of a satellite to gain angular momentum. Some nonhomogeneity is created by the discrete current concentration in volcano throats. The main effect is probably caused by dipole inhomogeneity of the magnetic field: the greater force acts on the hemisphere facing Jupiter. So the satellite's axial rotation ω will be slower than its orbital rotation n. The torque created by the dipole component of the Jovian field is estimated as

$$T_B \approx I\frac{dB}{dD}R_s^3 = -3IBR_s^3/D \quad (2)$$

This torque is balanced by the torque applied by Jupiter to the tidal bulges of the satellite[31]

$$T_Q = \frac{3}{2}\frac{kGM^2R_s^5}{D^6}\sin 2\delta \quad (3)$$

Where k is the Love number (for the Moon $k=0.02$, for Mercury $k=0.05$ (ref. 31), we assume $k=0.02$), δ is the lag angle of the bulges due to the internal friction in the satellite ($\delta\approx0.005$ for the Moon). In strongly asynchronous rotation, the Earth-type planets behave as solid bodies and $\delta\approx$ constant is a good approximation. But in fully synchronous rotation ($n=\omega$) there must be $\delta=0$, so that $\delta\to0$ at $n-\omega\to0$. Physically it is quite understandable: under the long-time load the creep begins to work and the matter flows, thus reaching the hydrostatic equilibrium. For fluids $\delta\propto(n-\omega)$ (ref. 32). We assume $\delta=0.005(n-\omega)/(n-\omega)_0$, here $(n-\omega)_0=2\pi/P_0$ (a similar dependence has been accepted elsewhere[33–35]). Equating the torques (2) and (3) we find at $I=I_{max}$, the values $n-\omega=2\pi/\Delta P$, where ΔP is the period of the 'lost' revolution. At $P_0=10h$ the rotation of the galilean satellites relative to the synchronous position makes up ~1—10 arc min yr^{-1} (the equatorial velocity ~10–100 m yr^{-1}) (see Table 1). This is a rather small but detectable value, the measurement of which will allow us to specify the models of the satellites and the details of their interaction with Jupiter and its environment.

Evidence of SO_2 on Io from UV observations

J. L. Bertaux

Service d'Aéronomie du CNRS, 91370 Verrieres-le-Buisson, France

M. J. S. Belton

Kitt Peak National Observatory, PO Box 26732, 950 North Cherry St, Tucson, Arizona 85726

Gaseous SO_2 was discovered on Io, the innermost galilean satellite of Jupiter, by the IRIS IR Michelson interferometer[1] on board Voyager 1 in March 1979. This SO_2 is likely to be associated with eruptions of the seven active volcanoes discovered at the same time by the Voyager cameras[2]. The UV spectrum of the solar light reflected by the surface of Io should be modified by the transmission $\bar{S}(\lambda)$ of a SO_2 atmosphere and by the reflectivity $r(\lambda)$ of the surface. Both gaseous SO_2 and solid[3] SO_2 present a deep absorption band around 290 nm. We have examined a published spectrum of Io taken in 1978 by the IUE Earth-orbiting telescope[4], and found an absorption dip centred around 290 nm in the albedo curve. We attribute this dip to gaseous SO_2, with a possible contribution of solid SO_2. However, the absorption dip is smaller than if the gaseous SO_2 quantity measured by Voyager 1 in the IR were uniform. It can be better represented by an SO_2 frost controlled gaseous atmosphere and a temperature distribution of Io's surface compatible with observations.

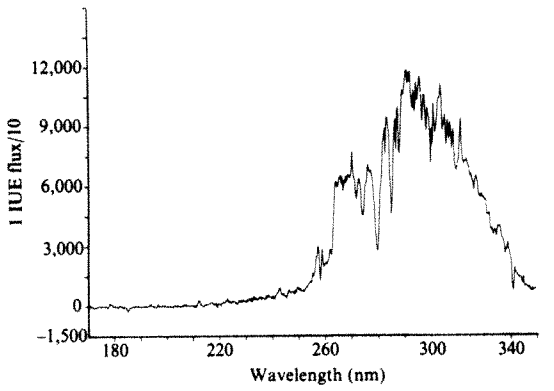

Fig. 1 The UV spectrum of Io as measured in 1978 with the orbital telescope IUE[4].

The surface of Io, even when covered with SO_2 frost, probably does not have the same UV optical characteristics as pure SO_2 frost obtained in the laboratory, as other materials are certainly present at the surface. To conduct a quantitative analysis, we have considered successively two extreme cases: either the surface reflectivity of Io does not show the absorption dip of pure SO_2 frost (which does not exclude its presence) or it reproduces it exactly (and therefore indicates its presence).

The average surface temperature of Io on the dayside is $\simeq$127 K, but some 'hot spots' exist where the temperature is probably as high as 290 K (ref. 5). This high temperature, which yields a high surface IR radiance, allowed the identification of an SO_2 absorption feature at 1,350 cm^{-1}. The vertical column density N is estimated to be 0.2 cm atm (ref. 1) which corresponds to a surface pressure of 1.0×10^{-4} mbar. This value is close to the vapour pressure of SO_2 frost at $T=129$ K (1.4×10^{-4} mbar). The similarity of these numbers led to suggestions that gaseous SO_2 content in Io's atmosphere is controlled by SO_2 frost. This idea is also supported by the recent identification of absorption due to SO_2 frosts in ground-based IR reflection spectra[6,7].

The geometric albedo of Io has been measured down to 320 nm from ground-based observations[8] and is displayed in Fig. 2. Further in the UV, the spectrum of Io in Fig. 1 has been measured with IUE[4], as was the spectrum of Mars. We derive the geometric albedo G(Io) below 320 nm from these data by using the relation:

$$\frac{G(\text{Io})}{G(\text{Mars})}=C\frac{\text{Spectrum (Io)}}{\text{Spectrum (Mars)}}$$

where C is a constant of proportionality which depends on the IUE observing conditions. The geometric albedo of Mars is obtained from measurements by OAO 2 (ref. 9), which is rather flat in this region (from 0.051 at 240 nm to 0.040 at 330 nm). The value of C was found to be 0.5 by matching the IUE albedo and the ground-based albedo at 330 nm. G(Io) is displayed in Fig. 2 and shows a pronounced dip, centred near 290 nm, reminiscent of the absorption coefficient K_λ of gaseous SO_2 also shown in Fig. 2. The vertical optical column density of 0.2 cm atm represents a vertical optical thickness $\tau_v(\lambda)=k_\lambda N$ of 6×10^{-3} at 340 nm and 3.5 at 280 nm. As only the integrated albedo on the surface is available, we computed the averaged transmission $\bar{S}(\lambda)$ of various SO_2 atmosphere models, assuming that the temperature of SO_2 frost controlled the gaseous SO_2. The vapour pressure ρ of gaseous SO_2 over frost is a function of surface temperature T (ref. 10)

$$\log_{10}\rho(\mu\text{ bar})=-1{,}843.04/T+13.7164$$

and the vertical column density is $N(\text{cm atm})=1.96\,\rho(\mu\text{ bar})$. Given a temperature distribution $T(\theta)$ as a function of solar zenith angle θ, the transmission $S_\lambda(\theta)$ of the atmosphere to reflected sunlight at 0° phase angle is $S_\lambda(\theta)=\exp[-2k_\lambda N(\theta)/\cos\theta]$. If $r(\lambda)$ is the normal reflectivity of Io's surface in the absence of atmospheric absorption, the geometric albedo at 0° phase angle is:

$$G(\lambda)=r(\lambda)\int_0^{\pi/2}\cos^{n+1}\theta\,S_\lambda(\theta)\,d(\cos\theta)=r(\lambda)\bar{S}(\lambda)$$

which defines the equivalent transmission $\bar{S}(\lambda)$. n is an index representing the limb darkening effect. However, we present here results only for $n=0$, as the dependence on θ is strongly dominated by the function $T(\theta)$. We have computed the equivalent transmission $\bar{S}(\lambda)$ for various temperature distributions $T(\theta)$ and have compared it with the measurement $G(\lambda)$ of Fig. 2. We take first a model for $r(\lambda)$ below 340 nm, with no SO_2 frost absorption dip, as a linear extrapolation of the trend observed above 340 nm. At 240 nm, where SO_2 absorption coefficient is small, this model (dashed line on Fig. 2) coincides with the measured $G(\lambda)$.

First we considered uniform temperature distribution. With a temperature $T=127.2$ K giving $N=0.2$ cm atm, we find $\bar{S}(340\text{ nm})=1$ (negligible absorption) and $\bar{S}(280\text{ nm})=2\times10^{-4}$ (total absorption). As $r(\lambda)$ must be <1, it implies that the albedo should be effectively zero at 280 nm. In fact, the non-zero albedo measured at 280 nm implies either a very low uniform value of $N(\simeq0.014$ cm atm corresponding to $T=117.4$ K) or a non-uniform distribution of the temperature and SO_2 column density.

We then considered models of the form

$$T(\theta)=T_s-\Delta T(1-\cos^m\theta)$$

where T_s is the temperature at the sub-solar point, $T_s-\Delta T$ the temperature at the terminator, and m a parameter describing how fast $T(\theta)$ decreases from T_s to $T_s-\Delta T$. For each value of T_s and m, a value of ΔT can be found which satisfies the observational constraint $\bar{S}(\lambda)\simeq0.50$ at 290 nm. The value of $m=1/4$, which provides a good empirical representation on

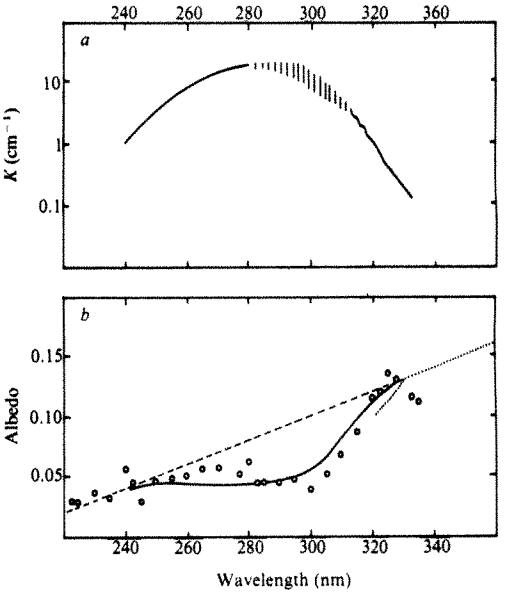

Fig. 2 *a*, The absorption coefficient K, of gaseous SO_2 as a function of wavelength[10]. There is a pronounced band structure between 280 and 320 nm which is represented schematically only. *b*, Geometric albedo of Io as a function of wavelength. Dotted line, ground-based measurements[8]. The linear extrapolation of ground-based measurements below 330 nm (dashed line) represents surface reflectivity variations $r(\lambda)$, if the SO_2 frost signature is ignored. ○, The measurements derived from spectrum of Fig. 1, spectrum of Mars and the known albedo of Mars. The solid line is the result of a computation of the transmission of a saturated SO_2 atmosphere (averaged over the disk of Io) above SO_2 frost, containing 0.2 cm atm at the sub-solar point, and a temperature variation compatible with IR measurements.

Mercury's temperature profile, would imply small values of T_s and large values of ΔT: $T_s = 123$ K and $\Delta T = 60$ K, which do not fit the IRIS data of $T_s = 127$–130 K, and $T = 110$ K at the evening terminator (ref. 1 and J. Pearl, personal communication). For $m = 1$, a good fit of $G(\lambda)$ is obtained with $T_s = 127$ K (corresponding to $N = 0.19$ cm atm) and $\Delta T = 34$ K and is represented in Fig. 2. This is quite reasonable, as we expect the morning terminator to be colder than the evening terminator. We, therefore, conclude that there was, at the time of IUE observations, a quantity of gaseous SO_2 comparable to the quantity detected by Voyager 1, if the temperature distribution was represented by $T = T_s - \Delta T(1 - \cos\theta)$, and if the surface reflectivity $r(\lambda)$ behaves as assumed, without any UV SO_2 frost signature.

Now we consider the other extreme case where the surface of Io has a reflectivity $r(\lambda)$ reproducing exactly the UV SO_2 frost signature. Indeed, it has been suggested[3] that the decrease of geometric albedo from 330 to 320 nm (ground observations) may be due to SO_2 frost. A laboratory reflectivity spectrum of pure SO_2 frost at 130 K was recently obtained[12], showing a decrease of a factor of 28 between 325 and 275 nm. Such a decrease is clearly absent from IUE observations, which would mean in this case that only a fraction $A_f \simeq 0.24$ of the planet is covered with SO_2 frost, the rest being covered with a background material with a reflectivity $\alpha_B \simeq 0.064$. This is obtained by fitting IUE observations at 275 and 325 nm with a combination of background material, pure SO_2 frost and gaseous SO_2 over this SO_2 frost. In such a case, the absorption due to gaseous SO_2 at 275 nm would be ~12%, averaged on the whole disk.

The UV spectrum of Io shows evidence of the UV SO_2 band centred at 280 nm. To what extent this band has a contribution of SO_2 frost or is only due to gaseous SO_2 is still an open question. It could be solved by resolving the spectral structure of the gaseous SO_2 between 280 and 310 nm, absent from the pure SO_2 frost spectrum. However, our model of the temperature-controlled SO_2 atmosphere has shown that the variations of $\bar{S}(\lambda)$ are much smaller than the variations of the gaseous SO_2 absorption coefficient k_λ, requiring, therefore, accurate measurements. The monitoring of the geometric albedo spectrum, from ground observations, but more conveniently from IUE, would provide a record of changes in the atmospheric SO_2 content. This SO_2 content is a result of volcanic activity, extent of SO_2 frost deposit, temperature profile, and escape to the ionised torus discovered by Voyager 1 at the orbit of Io[13]. It would be of particular interest to observe the rise and decay times associated with a large surge of activity.

We thank F. P. Fanale and R. M. Nelson for discussions and D. B. Nash for communication of pure SO_2 frost spectrum before publication.

Pioneer magnetometer observations of the Venus bow shock

C. T. Russell, R. C. Elphic & J. A. Slavin

Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California 90024

Venus has a bow shock in many respects similar to that of the Earth. The Venus bow shock was probed twice by Mariner 5, once by Mariner 10, Venera 4, and Venera 6 (refs 1–4 respectively) and repeatedly by Venera 9 and 10 (ref. 5). The Pioneer Venus orbiter is now circling Venus in a 24-h elliptical orbit which crosses the bow shock twice a day[6]. Here we report the somewhat surprising result that the Venus bow shock is not as strong as the terrestrial bow shock.

The orbit of the Pioneer Venus spacecraft is inclined at 105° to the ecliptic plane with periapsis at a latitude of 17°N and at an altitude of ~150 km. This orbital geometry provides shock crossings principally at solar zenith angles of greater than 60°. Figure 1 shows several recent shock crossings as recorded in the change in magnetic field strength. The shocks are ordered from top to bottom in terms of increasing θ_{BN}, the angle between the interplanetary field direction and the model[7] shock normal. The angle, θ_{BN}, has been found to order the observed structure of the terrestrial bow shock and the waves upstream of the shock[8]. Similar control is observed here but it is not yet clear whether the control is identical to the terrestrial case.

On each panel for $\theta_{BN} \geq 50°$ we have listed the field jump in the plane of the shock as determined from 1-min averages again using a shock model to determine the direction of the local shock normal. The average jump is 2.72 ± 0.16. We have repeated this analysis for nine terrestrial shock crossings at similar solar zenith angles and angles, θ_{BN}, observed by the ISEE spacecraft during December 1977. The average field increase in the plane of the terrestrial shock was 3.37 ± 0.07, almost 25% stronger. Further, the overshoot in field strength so obvious in the terrestrial shock[9] can barely be recognised in the typical Venus shock crossing.

Figure 2 shows that the weakness of the Venus shock extends over all solar zenith angles sampled to date. Here we plot the jump in the total field, not just in the plane of the shock, for 83 bow shock crossings in the range of solar zenith angles from 60° to 110°. The upper dashed line is the jump in field strength predicted by a gasdynamic simulation of the solar wind–Venus interaction.[10] The Mach number of the incoming flow is 6 and the ratio of specific heats is 5/3 for this simulation. The jump in total field for our nine comparison terrestrial shocks was 3.11 ± 0.10 at a median solar zenith angle of 72°. We note that the observed field jump at the Venus bow shock does decrease with increasing solar zenith angle as in the gasdynamic simulation.

The reason for the weakness of the Venus bow shock relative to the terrestrial bow shock is not obvious. In the gas-dynamic simulation one can decrease the amplitude of the shock jump by increasing the ratio of specific heats from 5/3 to 2, but it is not evident why this ratio would be different for the two planets. We would not expect the Mach number to be significantly different at the two planets.

If the difference in shock strengths were due to some radial variation of solar wind properties we would expect that the shock at Mercury would be even weaker than the Venus shock. this is clearly not so of the two perpendicular shocks seen by Mariner 10 (refs 4, 12) one was comparable to the terrestrial shock in strength and one to the Venus shock.

We have restricted our comparison to a similar range of solar zenith angles, and in this range of angles the shock shape is the same for the two planets[7]. Thus we cannot attribute the difference in shock strengths to differing shock geometries. We must conclude that there is something basically different about the solar wind interactions with the two planets. Perhaps this difference is the existence of photo-ion pickup[13] or charge exchange with the Venus geo-corona[14]. A similar conclusion is suggested by the unexpected closeness of the bow shock to Venus[7,15].

Heterogeneous photocatalytic reduction of dichromate on n-type semiconductor catalysts

Hiroshi Yoneyama, Yukiyasu Yamashita & Hideo Tamura

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadakami, Suita, Osaka 565, Japan

Photocatalytic and photoelectrosynthetic processes[1] are interesting from the point of view of solar energy utilisation. These processes can be developed using semiconductor electrochemistry[1-9]. The fixing of carbon dioxide on semiconductor powders[10] and amino acids synthesis on platinised TiO_2 (ref. 11) are good examples. Here we report the photocatalytic reduction of dichromate to Cr(III) on n-type semiconducting powders. This is important as dichromate is a harmful substance, and has to be treated with a reducing agent such as sodium thiosulphate to give Cr(III) in the first step of the waste treatment.

The basis of the photocatalytic reduction of dichromate is that the reaction is composed of the following two electrochemical processes;

$$2Cr_2O_7^{2-} + 28H^+ + 12e^- \rightarrow 4Cr^{3+} + 14H_2O \quad (1)$$

$$6H_2O \rightarrow 3O_2 + 12H^+ + 12e^- \quad (2)$$

Overall:

$$2Cr_2O_7^{2-} + 16H^+ \rightarrow 4Cr^{3+} + 8H_2O + 3O_2 \quad (3)$$

$$\Delta G^0_{298} = -115.8\ \text{kJ}$$

Although the overall reaction is thermodynamically feasible, dichromate is stable in aqueous acidic solutions. As the electrochemical oxidation of water usually requires a high overpotential, the difficulty of water oxidation seems to be responsible for the stability of dichromate ions in solution. As n-type semiconductors such as TiO_2, WO_3, α-Fe_2O_3 and $SrTiO_3$ can photosensitise the oxidation of water[12,13], these must be efficient photocatalysts for the reduction of dichromate ions.

It was found that the rate of the photocatalytic reduction follows equation (4);

$$-dC/dt = k\sqrt{C} \quad (4)$$

Table 1 shows the results obtained for different types of photocatalysts. The concentration of dichromate was determined by colorimetric analysis using diphenylcarbazide as a colour former. Table 1 shows that WO_3 was the most active. The quantum yield for the photocatalytic reduction on WO_3 at $\lambda = 400$ nm was 0.02, as determined by ferrioxalate actinometry.

Figure 1 shows an absorption spectrum of a dichromate solution and photocurrent spectra of WO_3 and TiO_2 electrodes in 0.5 M H_2SO_4. The absorption spectrum of the dichromate solution matches fairly well those of the semiconductor photocatalysts. Therefore, the light efficiency for photoexcitation of carriers is seriously weakened at the catalyst surface depending on the concentration of the solution and the thickness of the solution layer around the catalyst. The molar absorption coefficient of the dichromate solution at $\lambda = 350$ nm, where the maximum absorption was observed, was determined to be 2.24×10^3 M cm^{-1}, and that at $\lambda = 400$ nm, where WO_3 shows the maximum photoresponse, to be 4.4×10^2 M cm^{-1}.

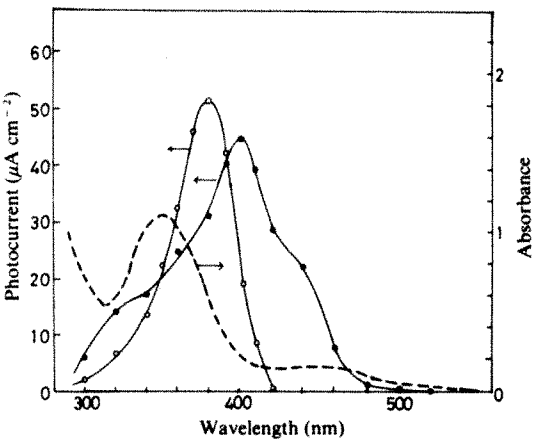

Fig. 1 Absorption spectrum of 5×10^{-4} M $K_2Cr_2O_7$ in 0.5 M H_2SO_4 and photocurrent spectra of WO_3 and TiO_2 electrodes at 0.8 V versus SCE in 0.5 M H_2SO_4. ●, WO_3; ○, TiO_2. These spectra are uncorrected for intensity variation of the lamp-monochromator output, with the drop off at shorter wavelengths attributable to the lamp. The WO_3 electrode was prepared by thermal decomposition of WCl_6 (ref. 14) and the TiO_2 electrode by thermal oxidation of a titanium plate[15].

The utilisation of solar energy in the photocatalytic reduction on WO_3 was investigated for dilute static dichromate solutions and for a concentrated agitated solution in the same way as described in Table 1. The results are given in Table 2. In spite of the high absorptivity of dichromate, the photocatalytic reduction was possible even for the solution conventionally used as a cleaning solution (no. 3 of Table 2) if that solution was stirred.

Figure 2 shows a steady-state current–potential curve of an illuminated WO_3 electrode in 0.5 M H_2SO_4 with and without dichromate ions. The polarisation curves were obtained with the illumination intensity adjusted to give the same anodic photocurrent at 1.2 V in both electrolytes with and without dichromate. In the solution without dichromate, the photosensitised oxidation of water occurred at potentials >0.3 V versus SCE, in agreement with the results already reported[16]. As Fig. 2 shows, a cathodic current peak appeared at about 0.55 V when the electrode was illuminated in the dichromate solution. If there was no illumination, the cathodic current due to the

* Experiments were carried out in glass vessels of 40 mm diameter, 30 mm high, or of 80 mm diameter, 10 mm high covered with saran wrap.
† In the static mode of the reaction, the catalyst stayed on the bottom of the vessel.
‡ The solutions in nos 1 and 2 were prepared by dissolving dichromate in 0.5 M H_2SO_4 and that in no. 3 into 18 M H_2SO_4.

reduction of dichromate, which occurs at potentials <0.8 V with superposition of the oxygen reduction, was much smaller than that obtained under illumination and showed no current peak. The cathodic process in the dichromate solution was also enhanced at TiO_2 electrodes, although to a lesser extent than with the WO_3 electrode. No enhancement was observed at a single crystal $SrTiO_3$ electrode.

Figure 2 suggests that the expected electrochemical mechanism prevails in the photocatalytic reduction of dichromate, because the cathodic process of the dichromate reduction occurs at potentials greater than the onset potential of the oxidation of water. According to equations (1)–(3), the reduction to Cr(III) should be accompanied by the evolution of oxygen, but no appreciable evolution was observed in the experiments shown in Tables 1 and 2. However, small bubbles evolved intermittently from the surface of a WO_3 layer packed half way up a reaction vessel (15 mm diameter, 45 mm height) when the catalyst was kept still and xenon light was focused onto a zone of the packed $WO_3/10^{-3}$ M dichromate solution interface.

Where the photocatalytic reaction is governed by an electrochemical mechanism, a high reaction rate will be expected if the catalyst gives high cathodic current at potentials where the photo-anodic reaction occurs. In the case of WO_3, the cathodic process is largely enhanced by illumination as stated above, so that the highest reaction rate must be achieved. The rate of the cathodic reaction seems to be governed by both the degree of the enhancement by illumination and electrocatalytic activity of the material itself in the dark. The order of the catalytic activity shown in Table 1, that is, WO_3 > rutile > anatase > α-Fe_2O_3 > $SrTiO_3$, seems to reflect such a situation.

A cathodic process is not usually enhanced at n-type semiconductors, as electrons as the major carrier participate in this process. Therefore, the results obtained here are not popular in semiconductor electrochemistry, although a similar phenomenon was observed on photocatalytic oxidation of methanol on TiO_2 (ref. 17). To clarify the mechanism of the photocatalytic reduction of dichromate, this problem has to be clarified. These preliminary results indicate that photoadsorption of dichromate may have some role in the enhancement of the cathodic process.

Tropospheric ozone and climate

J. Fishman*, V. Ramanathan†, P. J. Crutzen† & S. C. Liu‡

Analysis[1] of the observed tropospheric ozone distribution has revealed that concentrations in the Northern Hemisphere were larger than in the Southern Hemisphere. This finding and the earlier identification of the necessary photochemical reaction scheme[2] has led Fishman and Crutzen[1] to suggest that an appreciably larger *in situ* photochemical source of tropospheric ozone may exist in the Northern Hemisphere than in the Southern Hemisphere and to speculate that anthropogenic activity might be responsible for a considerable fraction of the larger ozone concentrations in the Northern Hemisphere. In the present study, we examine the influence of tropospheric ozone on climate. Ozone is an optically active gas, which absorbs and emits terrestrial IR radiation in the 8–10-μm region and absorbs solar radiation in the UV and visible. Hence, a change in ozone concentrations will perturb the radiative energy budget of the Earth–atmosphere system which may in turn perturb the climate.

Table 1 O_3 and CO source strengths (in molecules $cm^{-2} s^{-1}$)

	Northern Hemisphere	Southern Hemisphere	Ref.
Carbon monoxide			
Industrial CO emissions	19×10^{10}	4×10^{10}	7
CO from methane oxidation	$4–8 \times 10^{10}$	$4–8 \times 10^{10}$	5
Ozone			
From *in situ* production	$12–32 \times 10^{10}$	$5–14 \times 10^{10}$	5
From stratospheric injection	$5–8 \times 10^{10}$	$3–4 \times 10^{10}$	8–10

The ozone–climate problem has been studied mainly by radiative–convective models (see review in ref. 3). The recent study by Ramanathan and Dickinson[4] revealed that a uniform percentage decrease of ozone in the troposphere has about the same net radiative cooling effect on the surface–troposphere system as the same percentage decrease of ozone in the stratosphere. This result is surprising as only about 10% of all ozone resides in the troposphere. The relatively strong sensitivity of the terrestrial radiative energy balance to a tropospheric ozone change is caused by several factors[4], the principal one being that the integrated 9.6-μm band opacity of ozone is a function of atmospheric pressure. More specifically the line halfwidths of the individual rotational lines of the 9.6-μm band are linearly proportional to pressure, at least below 30 km. Consequently, although only ~10% of ozone is present in the troposphere, the IR opacity of tropospheric ozone is nearly the same as that of stratospheric ozone.

Our study will focus on the following aspects of the tropospheric ozone–climate problem: (1) interhemispheric differences in radiative heating of the surface–troposphere system caused by observed interhemispheric ozone distribution differences as reported by Fishman and Crutzen[1]; and (2) the sensitivity of surface–troposphere radiative heating to tropospheric ozone changes. The effects are estimated as a function of latitude and season.

Several recent studies have hypothesised that ozone concentrations may have increased substantially by industrial activities in the Northern Hemisphere and will continue to grow as human activity increases[1,5,6]. Admittedly, except in highly polluted air, it is difficult to prove, by direct observations the *in situ* photochemical production of tropospheric ozone from the oxidation of carbon monoxide and hydrocarbons in the presence of nitric oxide, because of the slow production of ozone in background air[5]. Table 1 summarises some of the studies which suggest that the amount of *in situ* photochemical production of ozone may be considerably larger than injection from the stratosphere[5,7–10] and Table 2 presents data that show the asymmetry in both the CO and O_3 distributions between the hemispheres[5,7,11–13].

Note that there are several reports which either support or refute the importance of tropospheric ozone production[1,5,6,10,14–17]. An indication that tropospheric ozone production does indeed take place in the Northern Hemisphere remote troposphere has recently been obtained from an analysis of simultaneous observation of the concentrations of CO and O_3, generally showing a positive correlation between about 2 and 8 km in the atmosphere[11].

Of similar importance for the production of ozone in the troposphere is the presence of hydrocarbons or carbon monoxide together with nitric oxide. The anthropogenic inputs for both CO and NO are now estimated to be comparable to the natural sources[15–21]. As these emissions probably take place simultaneously, they are of special importance for tropospheric ozone production.

The indications support the view that the asymmetric distribution of ozone between the hemispheres may to a substantial degree be the result of human activities. However, there is no undisputable proof that tropospheric ozone concentrations have generally increased in the Northern Hemisphere over the past decades, as a sufficient long-term record of tropospheric ozone observations is not available.

We use the radiative transfer model described elsewhere[4] which extends vertically from the surface to 54 km. Eight latitude bands are considered from the Equator to 70°, equally spaced at 10° intervals. The model computes the vertical distribution of IR and solar fluxes, using observed Northern Hemisphere distributions of temperature, humidity, clouds at three levels, CO_2, CH_4, N_2O and O_3, and surface albedo as a function of latitude and month. The radiative fluxes computed from these observed distributions are referred to as unperturbed fluxes.

The perturbation calculations discussed here are brought about by prescribing varying amounts of ozone in the troposphere; the change in stratospheric temperatures from the observed value is computed from radiative equilibrium considerations. It was found, however, that the stratospheric temperature changes had a negligible influence on the present results. The distribution of IR and solar fluxes is computed next and the differences between the fluxes in the perturbed and unperturbed troposphere are computed. The flux difference at the tropopause denotes the change in the net radiative energy input to the surface–troposphere system. It is this quantity which is considered here.

The standard profile is based on the observed distribution of ozone concentrations up to 12 km in the Northern Hemisphere as a function of month and latitude. We used three perturbations to our 'standard' profile of tropospheric ozone: (1) the ozone concentrations below 12 km were prescribed according to their distribution in the Southern Hemisphere[1]; (2) ozone concentrations were arbitrarily halved at all levels from the ground to 12 km from the standard distributions; and (3) the standard ozone concentrations were arbitrarily doubled up to 12 km. The first case would simulate the present day heating difference between the two hemispheres solely because more ozone is observed in the Northern Hemisphere than in the Southern Hemisphere troposphere. The second case examines the consequences of the assumption that tropospheric ozone in the Northern Hemisphere has already doubled due to anthropogenic activities. The doubling of tropospheric ozone considered in the third case is a projection into future anthropogenic influence on this gas.

The latitudinal distributions of the annual average values of the surface–tropospheric heating for the three cases are shown in Fig. 1. Considering first the interhemispheric differences, the latitudinal distribution of the difference in radiative heating rates between the Northern and Southern Hemispheres is due mainly to the latitudinal distribution of corresponding ozone concentration differences. At high latitudes, there are also significant seasonal variations in the interhemispheric ozone differences which cause corresponding seasonal variations in interhemispheric heating rate differences (not shown in Fig. 1). For example, at 50°N we calculate interhemispheric heating rates of 0.61, 0.77, 0.48 and 0.35 $W m^{-2}$ for winter, spring, summer and autumn, respectively. This seasonal variability is considerably less at low latitudes. However, more tropospheric ozone measurements in the Southern Hemisphere are needed before attaching too much importance to these seasonal variations. From Fig. 1, the hemispheric and annual mean value of the

Table 2 Observed hemispheric asymmetry of integrated CO and O_3 in the troposphere

	Asymmetry (Northern/Southern Hemisphere)	Latitudinal domain	Ref.

Ozone	1.3	60° S–60° N	5
	1.4	53° S–53° N	11
	1.2	90° S–90° N	12
	1.3	30° S–30° N	13

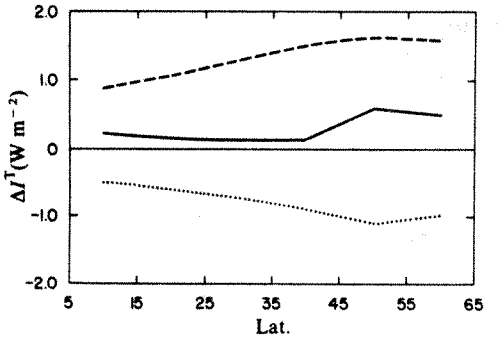

Fig. 1 Annual mean Earth–troposphere radiative heating (ΔI^T) resulting from tropospheric O_3 perturbations. Solid line, heating caused by interhemispheric O_3 differences; dotted line, heating caused by halving tropospheric O_3; dashed line, heating caused by doubling tropospheric O_3.

difference in the radiative heating rates between the Northern and Southern Hemispheres is about 0.3 W m^{-2}. This difference in radiative heating can be related to a corresponding difference in surface temperature, ΔT_s, by letting

$$\Delta T_s = \frac{\Delta I^T}{dI^T/dT_s} \quad (1)$$

where the numerator is the hemispheric average of the change in the energy input to the surface–troposphere system and the denominator is the climate sensitivity parameter which has been extensively discussed during the past decade or so. Values for this parameter[3,22] range between 0.75 and 2.5 W m^{-2} K^{-1}. We will choose the estimate derived by Ramanathan[23], dI^T/dT_s = 1.5 W m^{-2} K^{-1}, which is based on Wetherald and Manabe's[24] general circulation model climate sensitivity analysis. Introducing the difference of 0.3 W m^{-2} in heating between the hemispheres in equation (1), we obtain $\Delta T_s \approx 0.2$ K, that is, the Northern Hemisphere could be warmer than the Southern Hemisphere by about 0.2 K because of the larger amount of ozone in the Northern Hemisphere troposphere. Note that the Northern Hemisphere is indeed warmer than the Southern Hemisphere by abut 1.0 K (ref. 25). There are, of course, other inter-hemispheric differences, such as land and ocean distribution, cloud cover, snow and ice covered areas, and water vapour concentrations which together should be more important in explaining the observed temperature difference between the hemispheres than the differences in tropospheric ozone. Nevertheless, our calculations indicate that differences in ozone may contribute appreciably to the different observed mean temperatures. Applying equation (1) to the second and third cases shown in Fig. 1, we estimate that a halving of the tropospheric ozone concentrations may cool the surface by 0.5 K and that a doubling may warm it by 0.9 K.

We feel that considerations of man's alteration of the global climate must incorporate the possibility that tropospheric ozone concentrations may increase during the coming decades. Our calculations indicate that a doubling of the tropospheric ozone content, calculated by Logan *et al.*[6] to occur by the end of the next century, may increase surface temperatures by nearly 1 K. In a similar period of time a doubling of carbon dioxide in the atmosphere[26] will probably occur, which may result in a 2–3 K temperature increase[3]. A difference between these effects is that, as a result of shorter photochemical lifetimes, the heating resulting from increasing tropospheric ozone would be more concentrated in the Northern Hemisphere, whereas the heating by carbon dioxide would be distributed more evenly between the two hemispheres. It seems possible therefore, that the photochemical production of ozone in the troposphere may enhance the potential climatic consequences of future CO_2 increases by a substantial factor, in particular in the Northern Hemisphere.

Project Kiwi One: an acoustic cross-section of the South Pacific Ocean

D. G. Browning

Naval Postgraduate School, Monterey, California 93940

R. W. Bannister, R. N. Denham & K. M. Guthrie

Defence Scientific Establishment, Auckland 9, New Zealand

The deep ocean sound channel is used to obtain very long range (typically >2,000 km) acoustic transmission[1] via totally refracted propagation paths (SOFAR propagation[2]). Such experiments can therefore determine the acoustic transmission properties of large areas of ocean[3]. Those acoustic propagation experiments can be used to locate major oceanographic changes[4] and to identify specific water masses[5]. A 10,000-km underwater sound transmission experiment conducted between New Zealand and Peru to obtain an acoustic cross-section of the South Pacific Ocean is described here. Three distinct regions of transmission loss were found. The highest attenuation, which is attributed to Antarctic intermediate water, occurred in the central South Pacific Ocean.

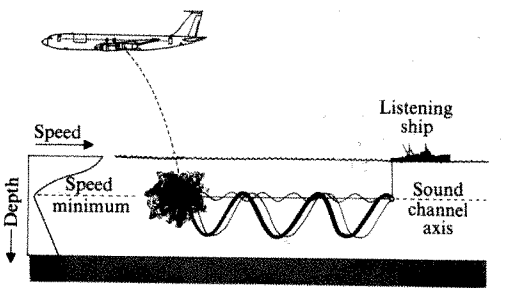

Fig. 1 Diagram of typical SOFAR propagation experiment.

© 1979 Macmillan Journals Ltd

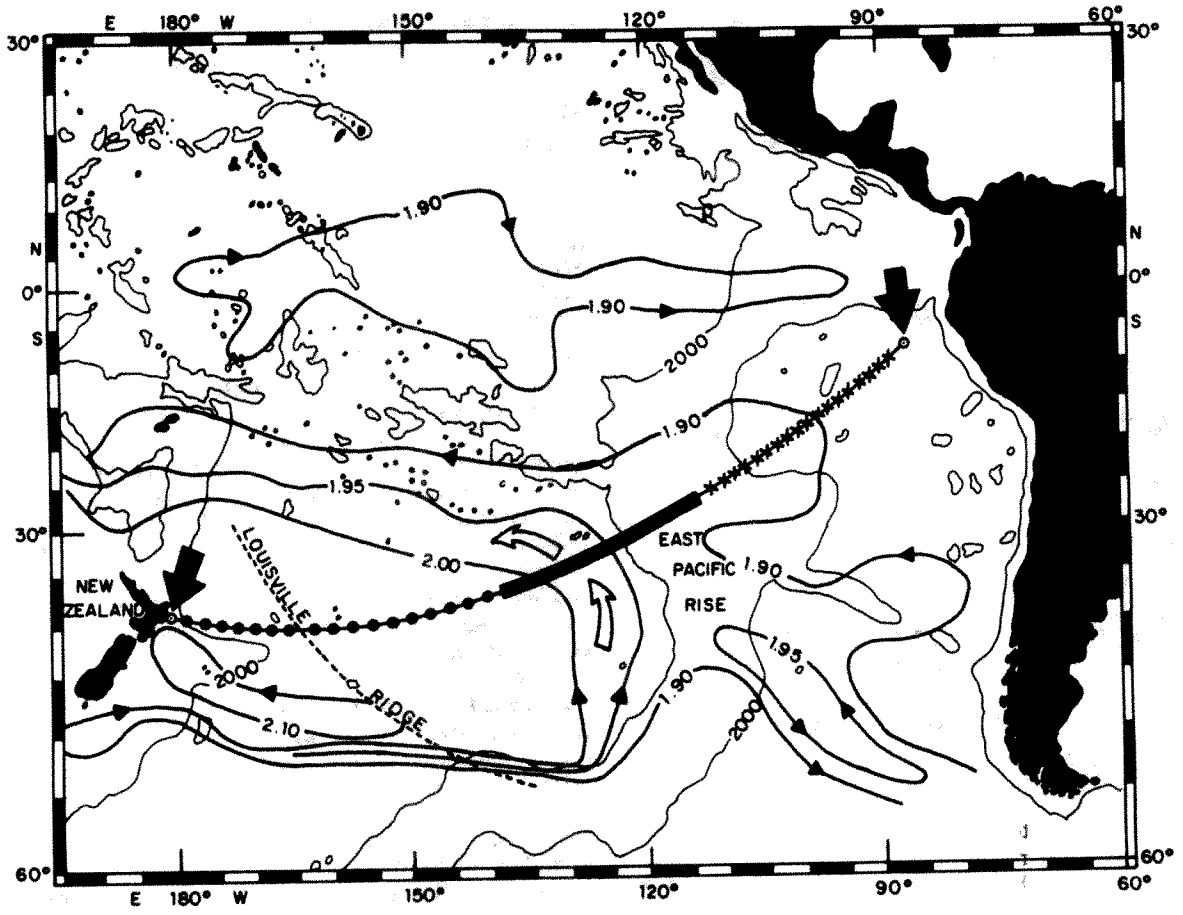

Fig. 2 Experimental track of Project Kiwi One. ⊙ designates receiver locations. Regions: *, eastern; ——, central; western. Dynamic contours (see ref. 15) indicate flow of AIW through central region (shown by arrows).

Although the South Pacific is the world's largest ocean, relatively little is known of its oceanographic and acoustic characteristics. Recent oceanographic cross-sections[6] indicate that there is a strong influx of Antarctic intermediate water (AIW) into the South Pacific from the polar regions as part of the principal anticyclonic gyre. Results from an acoustic experiment conducted in the Tasman Sea[7] indicate that such an influx would increase the attenuation of low frequency sound.

An ultra-long range sound transmission experiment to determine the acoustic properties and oceanographic regimes across the entire width of the South Pacific was jointly planned by US and New Zealand laboratories and designated as Project Kiwi One[8].

In a SOFAR propagation experiment (Fig. 1) both source and receiver are located near the axis of the deep ocean sound channel, which corresponds to a minimum sound speed. A cone of sound rays follows totally refracted paths along this axis, being only attenuated by the properties of the various water masses encountered.

The track of the Kiwi One experiment (Fig. 2) extended along a great circle between the North Island of New Zealand and the coast of South America near Peru, a distance of 10,000 km. Hydrophones to receive acoustic signals were located at each end of the track. Underwater sound signals (small explosive sources which detonated at the nominal depth of the sound channel axis, 1,100 m[9]) were dropped from an aircraft at 50-km intervals along the path. Flying such a total distance non-stop was a formidable task, achieved in ~16 h by a modified Boeing 707 aircraft with inflight refuelling[10]. The signals received from each sound source were recorded on magnetic tape at both receiving sites and later energy analysed through 1/3 octave filter bands with centre frequencies from 32 to 250 Hz.

Typical results are shown in Fig. 3 as a function of range for centre frequencies of 32, 64, 125 and 250 Hz. The range in this case is shown from the New Zealand receiver; similar results were obtained from the South American end. The transmission loss has been corrected for spreading loss, hence, the slope of a line fitted by a least squares analysis through the data points will give the rate at which sound is attenuated[11]. Three distinct changes in attenuation loss occur, designated as the western, central and eastern regions, each a distance of ~3,000 km. The highest attenuation is in the central region.

A plot of the resulting attenuation coefficients as a function of frequency (Fig. 4) shows that at the higher frequencies all regions approach the predicted regional values of attenuation for the South Pacific based on *p*H dependent absorption[12]. At

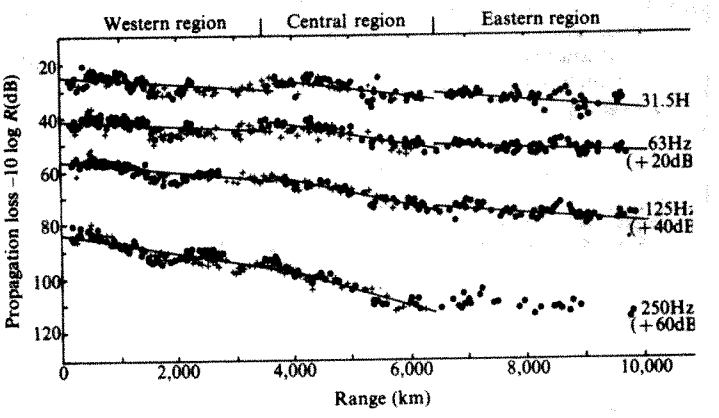

Fig. 3 Propagation loss (corrected for spreading loss) values obtained at New Zealand receiver for 1/3 octave filter bands. Levels shifted for clarity. Range is from New Zealand receiver. Fitted lines, by least square analysis, determine attenuation coefficients for each region. +, Eastbound; ●, westbound.

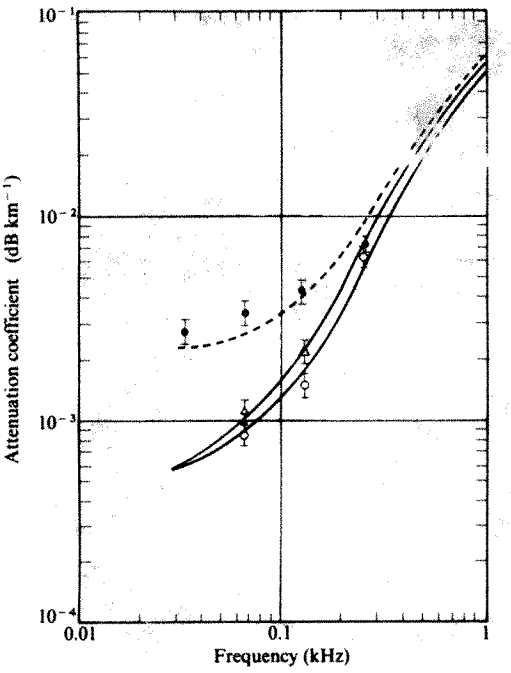

Fig. 4 Attenuation values measured in eastern region ○, central region ●, western region △ compared to attenuation obtained in Antarctic intermediate water (– – –), and subtropical water (——) in ref. 7. Upper solid line includes absorption component for western region, lower solid line includes absorption component for eastern region, based on ref. 12. Error bars indicate 90% confidence limits.

the lower frequencies, where it is hypothesised that the principal attenuation mechanism is scattering by oceanographic inhomogeneities[13], a significant difference occurs.

A comparison with water mass attenuation data obtained in the South Tasman Sea, which are similarly influenced by the Antarctic circumpolar current, shows good agreement and indicates that the eastern and western regions have values of attenuation characteristic of subtropical water masses while the central region has a higher attenuation characteristic of AIW. The higher attenuation in AIW has been attributed by Kibblewhite[14] to greater temperature inhomogeneities in this water mass. This influx of AIW into the central region at a depth near the sound channel axis is consistent with the Scorpio[6] data and the dynamic flow suggested by Johnson[15].

The acoustic data from a complete cross-section of the South Pacific Ocean shows three distinct regions of transmission loss, the highest occurring in the central region. The differences are due to changes in the value of low frequency attenuation. The results obtained were consistent with other attenuation measurements in Southern Hemisphere water masses and indicates that the higher attenuation in the central region is due to an influx of AIW.

Alanine enantiomeric ratio in the combined amino acid fraction in seawater

Jeffrey L. Bada & Edward A. Hoopes

Scripps Institution of Oceanography and the Institute of Marine Resources, University of California, San Diego, La Jolla, California 92093

In deep ocean waters the concentrations of free amino acids are very close to blank levels, while surface waters contain only very low quantities[1,2]. However, the concentration of 'combined' amino acids (whoch occur at all ocean depths in significant quantities) is roughly 10 times that of free amino acids[1,2]. These combined amino acids are bound in some sort of polymeric material and are released only on hydrolysis in strong acid. The combined amino acid material apparently has a substantial D-aspartic acid content; the D/L aspartic acid ratio in the combined amino acid fraction, isolated from water from the Sargasso Sea, is ~0.4 at all depths[2]. It has been suggested that combined amino acids were not actually part of the dissolved organic material in the oceans but were components of bacteria that passed through the filter used in the initial seawater-processing step[2,3]. Although in most organisms only the L-enantiomers of the amino acids are present, becateria contain several D-amino acids in their cell-wall proteins[4]. To verify the bacterial explanation we have carried out investigations into the enantiomeric composition of amino acids, besides aspartic acid, in the combined fraction. We measured the alanine enantiomeric ratio in seawater samples from three stations in the Pacific Ocean. Alanine was chosen because it is one of the more abundant components of the combined amino acid fraction in the oceans[1,2], and because D-alanine is a major component of bacterial cell-wall proteins[4].

The combined amino acids were isolated from the seawater samples using the procedures described elsewhere[1,2]. The D/L alanine measurements were made by gas chromatography, using the *N*-trifluoroacetyl-L-propyl peptide methyl ester method[5]. Some of the samples were sent to Dr K. Kvenvolden (US Geological Survey, Menlo Park, California) for independent analyses. The results in Fig. 1 show that the D/L alanine ratio has a value of around 0.5 in surface waters and increases to ~0.8–1.0 in deep water at all three stations. The ratios of the other amino acids measured were in the range of ~0.1–0.2 at all stations and depths. Also, the D/L ratios obtained at Scripps are compatible with those determined by Kvenvolden's laboratory.

If the combined amino acids in the oceans were simply bacterial components, then the results in Fig. 1 indicate that in deep waters, the bacterial proteins have a D/L alanine ratio close to 1.0. We feel it is unlikely, however, that bacteria would incorporate D- and L-alanine in a proportion close to 1.0, which is the chemical equilibrium ratio for the enantiomers. Also, deep water has been sampled at widely different locations and the D/L alanine ratio never exceeds 1.0. The various water samples might contain different bacterial species that would have differing D/L alanine ratios in their cell-wall proteins, and that they might have D/L alanine ratios both less and greater than 1.0. The fact that the D/L ratios do not exceed 1.0 suggests that we are observing the product of a chemical process, not a bacterial cell-wall component.

One explanation for the high D/L alanine ratio in the combined amino acids in deep oceanic waters is that racemisation has taken place. Racemisation has been observed in a variety of fossil materials and in deep-sea sediments (see ref. 6 for review). However, estimates of the racemisation rate in the ocean[2,7] indicate that it would require hundreds of thousands of years to produce a D/L alanine ratio of ~1.0; this is much longer than the mixing times of the oceans (see ref. 8). Alanine may, however, be a component of marine humus. As this material is

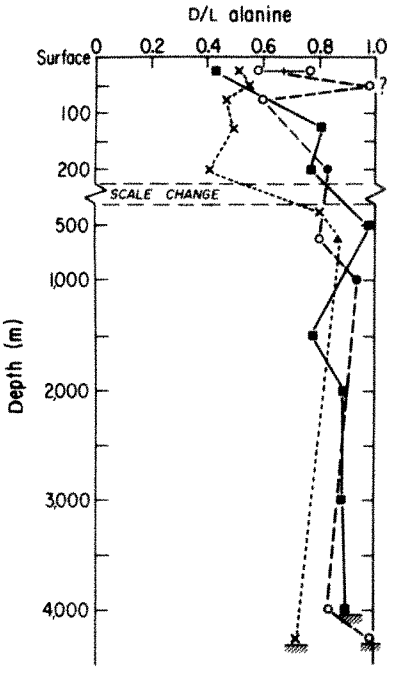

Fig. 1 The results of the D/L alanine measurements for stations: *a*, the North Pacific gyre (28°33.5′ N, 155°30.7′ W) (○); *b*, ~670 km south-west of San Diego (28°25.0′ N, 122°31.0′ W) (×); and *c*, ~60 Km off Peru (15°22.0′ S, 76°02.3′ W) (■). ● and ▲ are independent measuements carried out by Dr K. Kvenvolden and D. Blunt, US Geological Survey.

apparently highly unreactive and of considerable age[3], racemisation might have occurred during the time that the marine humus remains in the oceans. The extent of racemisation of the various amino acids in the combined amino acid fraction seems to discount this possibility. The relative rates of the amino acid racemisation reactions[6] indicate that aspartic acid would be more rapidly racemised than alanine, while glutamic acid should have a rate similar to alanine. This is not what we found for combined amino acids in the ocean; alanine was found to be the most highly racemised fo all the amino acids.

An interesting explanation for the high D/L alanine ratios in deep water and for the increase in the D/L alanine ratio with depth in the ocean involves a dehydration reaction of serine; this reaction produces alanine that is racemic (D/L ratio of 1.0). Serine dehydration has recently been found to occur in foraminiferal tests in deep sea sediments[9] and in fossil molluscs[10]. Several observations indicate that serine dehydration accounts for the high D/L alanine ratios in deep ocean waters. Our analyses indicate that serine is one of the more abundant components of the combined amino acids in surface waters, but a relatively minor component in deep waters, suggesting that this amino acid is fairly unstable and has decomposed. Whereas the serine content of the combined amino acid fraction decreases with depth, the alanine content increases; these observations are consistent with the serine dehydration pathway.

Threonine can also undergo dehydration via a pathway identical to that of serine, producing (in this case) the amino acid α-amino-N-butyric acid (ABA); the ABA produced by this mechanism is racemic[9]. ABA is a non-biological amino acid and is apparently not produced by any pathway other than threonine dehydration. The presence of ABA in seawater therefore would be convincing evidence that the serine and threonine dehydration reactions occur in the ocean. A peak that had a retention time similar to ABA was present on the amino acid analyser chromatograms of all of the deep water samples. The surface water samples seem to contain a trace quantity of ABA; the relative amount of ABA increased in the deep water samples relative to that in surface waters. To confirm that ABA was indeed present in deep oceanic waters, we analysed a 20-l water sample collected from a depth of 2,800 m at a station ~670 km off the coast of southern California. We collected the fraction in which the ABA peak eluted from the amino acid analyser column. This fraction was then desalted and analysed by gas chromatography. (The procedures used for the ABA collection and the subsequent analysis are identical to those described elsewhere[9].) The gas chromatographic analysis indicated the presence of two peaks which had retention times identical to those of the D and L enantiomers of ABA. Moreover, the gas chromatographic results indicate that the D/L ABA ratio was ~1.0, in accord with that predicted from the threonine dehydration pathway.

These various results show that the dehydration reactions of serine and threonine are quite possibly taking place in the oceans; this therefore provides some of the first experimental evidence that chemical diagenesis of dissolved organic material occurs in the sea. Alteration reactions, such as serine and threonine dehydration, may cause the organic material in the ocean to be less biologically useful, and thus they could partially explain why the bulk of the dissolved organic carbon in the oceans is of considerable age[3]. Nothing is known about the rate of the serine and threonine dehydration reactions in the oceans. Future investigation of the kinetics of these reactions should provide important new insights into the reactivity of the dissolved organic material in the sea.

We thank the captains, marine technicians and crews of RVs E. B. Scripps, Thomas Washington, Knorr, and New Horizon for their expert assistance. We also thank Drs Stanley Watson and Kenneth Smith for shiptime. This work was supported by the Office of Naval Research (N00014-75-C-0152).

The surface charge of suspended particles in estuarine and coastal waters

K. A. Hunter* & P. S. Liss

School of Environmental Sciences, University of East Anglia, Norwich, UK

The colloidal stability of particles transported in suspension by rivers is controlled by surface electrical properties[1] which are conventionally regarded as undergoing rapid change during estuarine mixing[1–3] by interaction with polyvalent ions, especially Ca^{2+} and Mg^{2+}. Although wide differences in rates of coagulation of clay minerals as a function of salinity have been demonstrated in the laboratory[4,5], Gibbs[6] and others[7,8] have concluded that field studies provide no real evidence for the importance of such differential flocculation. Instead, changes in clay mineral distribution with distance from the source river can be accounted for by differences in the particle size spectra and the resulting sedimentation velocities. The effects of differing electrical and surface properties on coagulation rates are apparently suppressed by the formation of uniform films of metal oxides and/or organic matter around the particles[6]. We present here direct measurements of the electrokinetic charge on river and estuarine particles which confirm this hypothesis.

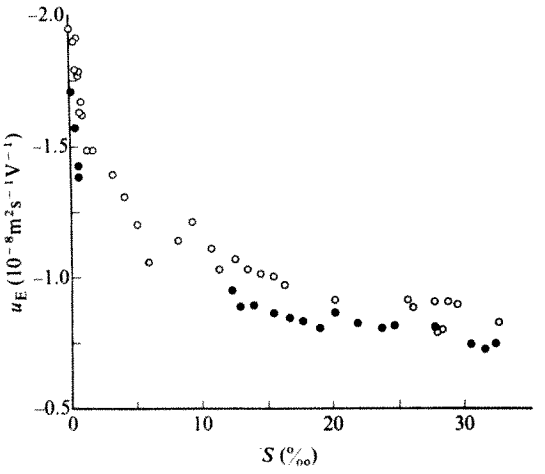

Fig. 1 Electrophoretic mobility (u_E) of particles collected in the Conwy estuary as a function of salinity (S). ●, 29 April 1979 survey; ○, 17 June 1979 survey. The electrophoretic mobility is the velocity per unit of applied electric field of particles moving at the stationary levels of the cell. Field strength was calculated from the current passed at the time of measurement and the electrolyte conductivity, determined separately. Each point plotted is the mean of determinations on at least 10 particles at each of the two stationary levels. In addition, measurements were made for all particles in each direction by reversing the field polarity. The observed standard deviation of the values was typically 14% with most in the range 6–20%. This implies a standard error in mean u_E values plotted of typically 2–4% which was confirmed by repetitive measurement of a single sample.

River and estuarine samples (20–35 per survey) have been collected from the Alde (Suffolk, 8 February and 19 March 1979), Orwell (Suffolk, 16 April 1979), Beaulieu (Hampshire, 17 May and 4 June 1979) and Conwy (North Wales, 29 April and 17 June 1979). For each sample the salinity of the water and the electrophoretic mobility of the suspended particles were measured within about a week of collection; numerous prior tests showed that storage (at 6 °C in the dark) for this period led to no significant changes in electrophoretic mobility[9]. Mobilities were determined with a Rank Mark II particle electrophoresis apparatus using a rectangular quartz cell[9]. Full details of the procedure, which utilised Ag/AgCl electrodes and a miniature measurement cell to allow determinations to be made in full strength seawater, will be published elsewhere. Samples were analysed for dissolved organic carbon (DOC) and surfactant activity in the water. The results of these analyses and the method developed for the measurement of surfactant activity will be reported separately. River waters flowing into the estuaries were analysed for their major dissolved cationic components (Na^+, K^+, Mg^{2+}, Ca^{2+}).

Representative plots for the relationship between electrophoretic mobility (u_E) and salinity (S) are shown in Figs 1 (Conwy) and 2 (Alde). The results for the Beaulieu are very similar to those for the Conwy. Those for the Orwell closely resemble the results given for the Alde. A composite plot giving the combined data for all seven surveys is shown in Fig. 3. The electrophoretic mobility is the appropriate parameter to be used in discussing changes in electrokinetic behaviour, because it is the only quantity which can be measured directly in this type of experiment[10]. Its relationship to the electrokinetic or ζ potential and the electrokinetic charge density is theoretical and depends in a complex manner on particle radius of curvature and electrolyte concentration[11].

Figures 1–3 clearly show that the particles are negatively charged at all salinities. The negative charge at high salinity is in agreement with previous electrophoretic measurements made directly on suspended particles in seawater[9,12]. Figure 4 shows the results of electrophoretic measurements made on 160 individual particles in a sample of North Sea water, which confirm the absence of positively charged surfaces. In contrast to these findings, streaming current measurements made on coarse-grained sediment particles in seawater (natural or synthetic)/distilled water mixtures indicate a change from negative to positive ζ potential at salinities which range from 1.8 to >20‰ (refs 2, 3). This discrepancy may result from differences in the sizes of particles examined by each method or in the nature of the particulate material itself. In addition, the indirect nature of the streaming current measurements may have introduced significant changes through storage effects, chemical pretreatment of the sediments, lack of equilibration with the measurement electrolytes and (in some cases) the use of synthetic media. These factors will be of particular importance if natural surface coatings are removed or altered.

It is often assumed that flocculation of riverborne particulates occurs when their charge is neutralised on mixing with high ionic strength seawater in the estuarine zone[1]. The fact that all the particles examined in the present study have a substantial negative charge means that this mechanism of flocculation in estuaries is probably not important.

In the Alde and Orwell estuaries there is a gradual and almost linear decrease in negative mobility with increase in salinity. For the Conwy and Beaulieu estuaries a similar decrease occurs in the mid to upper salinity regions, but at low salinities u_E changes more dramatically. This division of the estuaries studied into two types (Figs 1 and 2) is almost certainly due to differences in river water composition. Both the Orwell and Alde rivers contain relatively high levels of dissolved cations, especially Ca^{2+}, whereas the Rivers Conwy and Beaulieu have substantially less dissolved salts. This means that in the calcareous rivers some of the natural electrokinetic charge of the particles will already be neutralised by incorporation of cations (particularly polyvalent ones) into the fixed part of the double layer, whereas for more acidic rivers, such as the Beaulieu and Conwy, this effect will not occur until the low salinity part of the estuarine zone. Support for this argument comes from laboratory experiments in which suspensions of seawater particles were mixed with high and low Ca^{2+} river waters and distilled water. Irrespective of the origin of the marine particulates, the high Ca^{2+} river water gave a u_E/S plot resembling Fig. 2, whereas low Ca^{2+} river water, and more especially distilled water, produced plots of similar shape to Fig. 1.

Apart from differences due to river water composition, the combined data in Fig. 3 show remarkably little dispersion and there is also good agreement between the results of independent surveys of the same estuary (Figs 1 and 2). Perhaps more importantly, the variations in u_E of individual samples are small (see legend to Fig. 1) indicating a high degree of surface uniformity. The results shown in Fig. 4 are typical in this respect; at

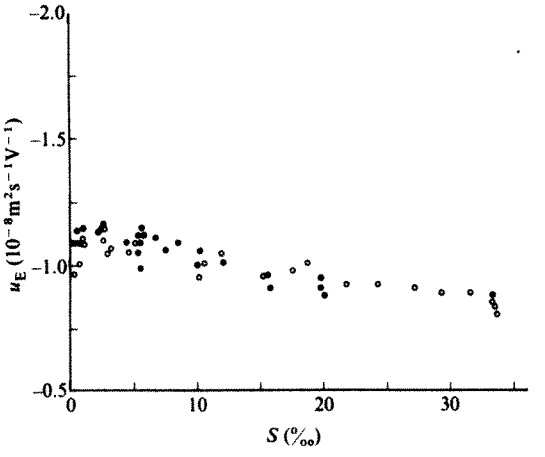

Fig. 2 Electrophoretic mobility (u_E) of particles collected in the Alde estuary as a function of salinity (S). ●, 8 February 1979 survey; ○, 19 March 1979 survey. Standard errors of mean u_E values are comparable to those of the Conwy estuary (Fig. 1).

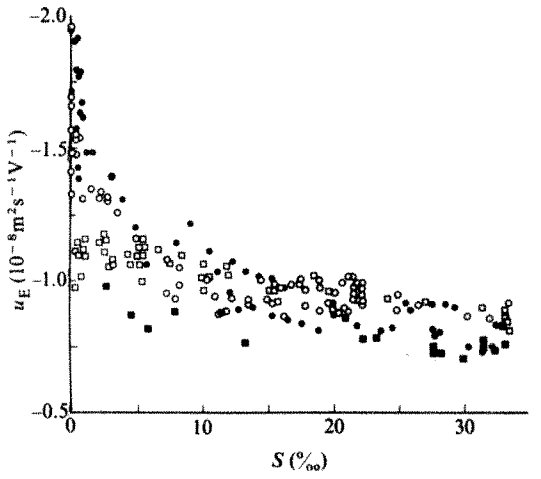

Fig. 3. Composite plot showing electrophoretic mobility (u_E) of particles as a function of salinity (S) for the four rivers studied. ○, Beaulieu estuary; ●, Conwy; □, Alde, ■, Orwell. Data for the two separate surveys of each of the first three estuaries have been combined in the one symbol.

least half of the total u_E variability (13%) in this case is attributable to experimental errors (mainly due to focusing)[13]. In view of the highly varied nature of the particle types involved (various clay minerals, aluminosilicates, quartz grains, calcite, living and dead organisms, detritus), the present results provide the first direct evidence of a dominant role of oxide and/or organic films in determining the surface properties of suspended estuarine particles. Previous work using similar methods has established that natural organic surfactants largely control the properties of surfaces introduced into seawater through the formation of cohesive films[9,12,14,15]. Surfactant activity and DOC results for the present surveys indicate levels of adsorbable organic matter in excess of those in seawater. Accordingly, in these estuarine systems organic coatings are expected to be at least as important as in seawater. With respect to control by oxide films, the Beaulieu estuary (Fig. 3) is an area of rapid removal of dissolved iron[16] and there is some evidence for uptake of the precipitated material onto particle surfaces[17].

As surface active organic matter is ubiquitous in natural waters, it seems reasonable to conclude that the basic principles revealed here are sufficiently general to apply in other areas. For example, the uniformity of electrokinetic charge on suspended estuarine particulates, arising from the dominant presence of surface coatings, is able to explain the apparent lack of evidence for differential flocculation of minerals in field studies of sediment distribution[6–8]. Furthermore, it seems likely that surface films will exercise a major role in chemical transformations involving particulate matter. Thus, for example, uptake/release of dissolved trace metals by particles may well depend on the chemistry of the organic matter forming the film rather than that of the underlying solid matrix.

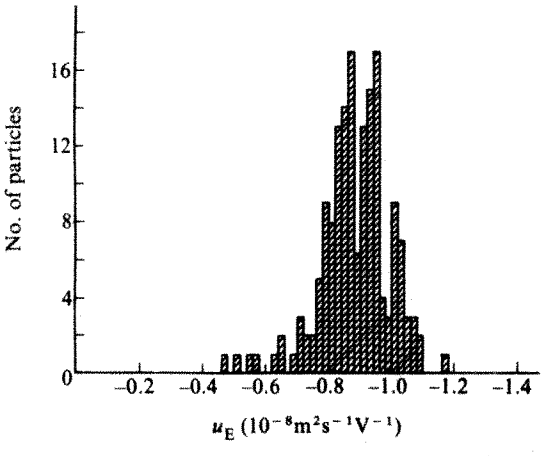

Fig. 4 Frequency histogram of electrophoretic mobility (u_E) of 160 natural suspended particles in coastal North Sea waters collected 6–7 km south-east of Great Yarmouth, Norfolk. Combined data for both stationary levels. Mean and standard deviation of u_E; $0.89 \pm 0.12 \times 10^{-8}$ m^2 s^{-1} V^{-1}.

We thank members of the Department of Oceanography, University of Southampton for their help with this work. The project was supported by a grant from the Natural Environment Research Council.

Helium and xenon in deep-sea basalts as a measure of magmatic differentiation

David E. Fisher

Rosenstiel School of Marine and Atmospheric Science, University of Miami, 4600 Rickenbacker Causeway, Miami, Florida 33149

There has been much recent interest in the rare gas abundances of terrestrial materials, due mainly to the discovery of 'excess' radiogenic Ar and He trapped in deep-sea glasses[1–4]. The abundances of these gases indicated that such materials might effectively trap the internal Earth's atmosphere, and evidence of trapped primordial gases has by now been found not only in deep-sea glasses[5–10], but also in xenolithic inclusions[11–15], deep ocean waters[16], CO_2 well gas[17–19], volcanic gas[20] and diamonds[21]. The rare gas elemental abundances measured in these samples may not quantitatively reflect the deep-Earth pattern. Several elemental fractionation processes have been suggested, ranging from selective enrichment of the lighter gases in an upward-rising magma[22,23] to posteruptive diffusion loss which would selectively deplete the lighter gases[24]. Each of these processes will affect concentrations of the helium and xenon isotopes in a characteristic manner, thus leaving in the glasses an isotopic fingerprint of what has occurred. New data are reported here which indicate extremely small concentrations of fissiogenic xenon in deep-sea basalts containing large concentrations of trapped excess radiogenic helium and argon. The resulting high $^4He_r/^{136}Xe_f$ ratios are diagnostic of fractionation during the magmatic processes leading to eruption rather than of posteruptive loss of gas (which would show the opposite effect). The results indicate that studies of volatiles in general and of the rare gases in particular in such mantle-derived samples, even in those with no subsequent alteration or contamination, may be profoundly influenced by mass-dependent pre-eruptive effects. The consequences of this fractionation for the deep-Earth K/U ratio are discussed.

Absolute accuracy is ±15% for Ar, ±20% for He and Xe.

Most terrestrial ^4He is due to the radioactive decay of the U and Th families. A small contribution to terrestrial Xe is due to the spontaneous fission of U. The Th/U ratio of non-sedimentary, non-metamorphic terrestrial rocks is 3 ± 1. The production ratio of radiogenic He(^4He_r) and fissiogenic Xe($^{136}Xe_f$) is nearly constant with time and with the nearly constant Th/U ratio ($^4He_r/^{136}Xe_f = 4.2\times10^8 \pm 10\%$). Finally, He and Xe are the lightest and heaviest of the rare gases, respectively, and so their separation by any mass-dependent process will show the largest possible effects. Therefore a $^4He_r/^{136}Xe_f$ ratio $\sim 4.2\times10^8$ in a given material is evidence that no significant mass fractionation effects have disturbed the rare gas pattern, a value $<4.2\times10^8$ is evidence for preferential loss of He, and a value $>4.2\times10^8$ is evidence for preferential He enrichment.

Samples of glassy basalts outcropping in the Vema Fracture Zone (Mid-Atlantic Ridge), previously shown to have high $^4He_r/^{40}Ar_r$ ratios characteristic of efficient trapping of the pre-eruptive rare gases[24], were selected for analysis. The samples were melted and partially vaporised in an r.f.-induction furnace, and the resulting gases were purified over two successive Ti-getters at various temperatures. Helium was measured while Ar and Xe were adsorbed on charcoal; the Ar and Xe were then successively released and measured. The instrument was a Reynolds-type steel 4.5″–60° mass spectrometer. Isotopic ratios were determined by extrapolation of several spectra sweeps back to entrance time; absolute amounts were calibrated by pure gas standards of atmospheric (except for He) isotopic composition run alternatively with the samples; blank runs were interspersed. A correction for instrumental mass fractionation was made on the basis of the standard gases. The results are shown in Table 1; the Xe isotopic data are plotted in Fig. 1. The linear relationship follows from:

$$^{136}Xe_t = {}^{136}Xe_f + {}^{136}Xe_m + {}^{136}Xe_a$$
$$= {}^{136}Xe_f + a({}^{132}Xe_m + {}^{132}Xe_a)$$
$$= {}^{136}Xe_f + a\,{}^{132}Xe_t$$
$$\frac{^{136}Xe_t}{^{132}Xe_t} = \frac{^{136}Xe_f}{^{132}Xe_t} + a$$

where the subscripts f, m, a, and t identify the fissiogenic, mantle, atmospheric, and total components respectively, and the a represents the $(^{136}Xe/^{132}Xe)_a$ ratio. The ratio $(^{136}Xe/^{132}Xe)_m$ is assumed identical to a; but if it were identical to that of the planetary primordial component observed in primitive meteorites the error is only 3% and does not affect the conclusion. A least squares fit to the data of Fig. 1 gives a straight line with coefficient of determination $r = 0.97$ and intercept 0.329, identical within limits of error with a. The data therefore indicate mixing of a constant fissiogenic component with varying amounts of atmospheric xenon. The slope of the line gives the concentration of $^{136}Xe_f \sim 6\times10^{-15}$ scc g^{-1} (scc, standard cubic centimetre). $^{136}Xe_f$ can also be calculated for the individual samples; these values are shown in Table 1.

The He in these samples is overwhelmingly radiogenic. The primordial $^4He/^3He$ ratio measured in gas-rich meteorites is ~3,500. ^3He has not been measured in the samples considered here, but the highest concentration measured in deep-sea glasses is about 90×10^{-12} scc g^{-1} (refs 8, 10), and therefore $^4He_p < 30\times10^{-8}$ scc g^{-1}, compared to the total measured values of $1{,}000$–$2{,}000\times10^{-8}$.

The resulting $^4He_r/^{136}Xe_f$ ratios are $>2\times10^9$ for all three glasses (Table 1). This is nearly an order of magnitude greater than the production ratio, supporting Alexander's suggestion of mass fractionation due to preferential upward migration of the lighter elements in the rising magma[22,23].

In this argument I have attributed the excess ^{136}Xe to spontaneous fission of ^{238}U. All the isotopes except ^{136}Xe are within limits of error of the atmospheric abundances, leading naturally to the supposition that it is something particular about ^{136}Xe that leads to its enrichment; yet the limits of error do not preclude some contribution from an alternative mechanism of isotopic enrichment of the heaviest xenon isotope, such as a mass fractionation process. Nevertheless, my conclusions remain valid despite any such possible complications. The low concentration of 'fissiogenic' xenon gives a high $^4He_r/^{136}Xe_f$ ratio, which indicates ^4He enrichment by fractionation of the lighter gas. If part of the excess ^{136}Xe attributed to a fissiogenic origin is actually due to mass fractionation (or to any other process) then the true concentration of fissiogenic xenon is correspondingly lower, the $^4He_r/^{136}Xe_f$ ratio correspondingly higher, and this only strengthens the argument that the light gases are enriched by the fractionation process. In turn this conclusion make the possiblity of the xenon being fractionated in such a manner as to enrich the heavier isotopes unlikely, thus leading back to the

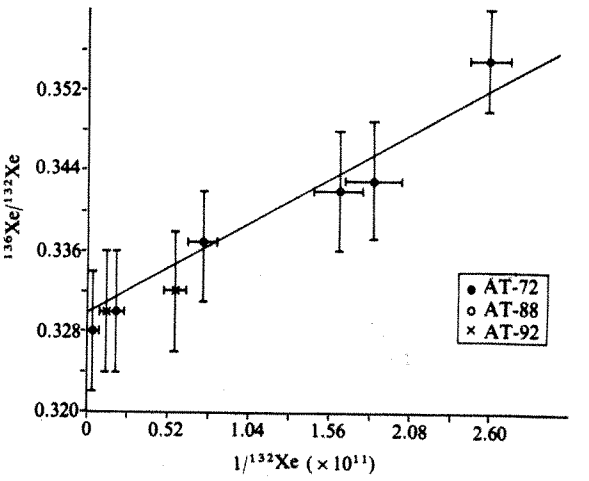

Fig. 1 Xenon isotopic ratios plotted against $1/^{132}Xe$ for the glasses.

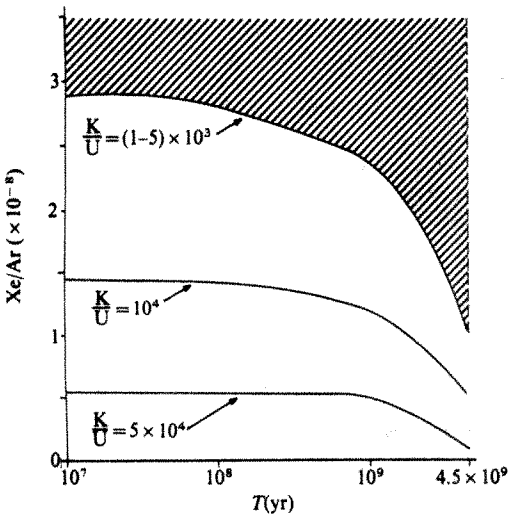

Fig. 2 The $^{136}Xe_f/^{40}Ar_r$ production ratio as a function of time.

conclusion that the excess ^{136}Xe is indeed fissiogenic. Therefore even if part of the measured excess ^{136}Xe is not fissiogenic, or if the magnitude of the excess has been overestimated, the conclusion that elemental fractionation of the rare gases has occurred remains valid; that is, the lighter-mass gases are preferentially enriched in these samples.

Previous arguments[24,25] assessing the terrestrial degassing history and/or the K/U ratio in the basalt source magma, based on the high $^4He_r/^{40}Ar_r$ ratio in these rocks, are now seen to be invalid as the He/Ar ratio must also have been enriched by this mechanism. It is not possible from these data to estimate quantitatively the effect on the He/Ar ratio, but we can use both the $^4He_r/^{40}Ar_r$ and $^{136}Xe_f/^{40}Ar_r$ ratios to set upper and lower limits to the K/U ratio. Although the results have no meaning for the present set of data, the calculation may be useful in future. The production ratio $^{136}Xe_f/^{40}Ar_r$ is shown in Fig. 2, the production ratio $^4He_r/^{40}Ar_r$ has the same form (see Fig. 1 of ref. 24). The age dependency can be eliminated by considering the ratio $^{136}Xe_f/U_m$. The uranium concentration of the oceanic upper mantle (U_m) has been estimated at >20 parts per 10^9 (ref. 26), giving

$$^{136}Xe_f/U_m < 3\times 10^{-7}\ \text{ssc g}^{-1}$$

and an age for accumulation of the rare gases $T < 4\times 10^8$ yr. This is an upper limit both because of the U limit and because the concentration of $^{136}Xe_f$ may have been enriched over the mantle value in these samples by the same process that led to enrichment of the He/Xe ratio. This age refers not to emplacement of the basalt on the sea floor but to accumulation of the radiogenic gases in the magma. The $^{136}Xe_f/^{40}Ar_r$ data of Table 1, compared to Fig. 2 for $T < 4\times 10^8$ yr, specify an upper limit of $K/U < 5\times 10^4$; the $^4He_r/^{40}Ar_r$ data, compared to the calculated production ratio (Fig. 1 of ref. 24) provides a lower limit of $K/U > 3\times 10^3$. These limits (which refer to the basalt source region) encompass nearly the total range of previous suggestions for the deep-Earth K/U ratio.

One other previous attempt to identify the mantle K/U ratio through rare gas data can be faulted by a similar analysis. Hennecke and Manuel measured a low $^4He_r/^{40}Ar_r$ ratio on a Hawaiian xenolith[12], concluding that this indicated generation from a K/U source of chondritic composition ($K/U \sim 5\times 10^4$). Their measured Xe displays a small excess at mass = 136 which can be identified as $4\times 10^{-15} < {}^{136}Xe_f < 24\times 10^{-15}$ scc g^{-1}; the $^4He = 35\pm 4\times 10^{-8}$ scc g^{-1}, so that $^4He_r/^{136}Xe_f < 9\times 10^7$, which indicates preferential loss of He. Therefore the low He/Ar ratio may be due to this He loss rather than to a chondritic source. On the other hand, in the Mitchell No. 7 CO_2 gas well of Harding Co., New Mexico, Zartman *et al.* found $^4He = 45\times 10^{-6}$ cm^3 per cm^3 (ref. 27), and Butler *et al.* found $^{136}Xe_f = 9\times 10^{-14}$ (ref. 17), giving $^4He_r/^{136}Xe_f = 5\times 10^8$. This result is well within experimental error of the theoretical value 4.2×10^8 and indicates no significant mass fractionation of the radiogenic gases. The measured $^4He_r/^{40}Ar_r$ ratio of 1.6 indicates a K/U source of $\sim 1\times 10^4$, but the source region for these wells probably reflects a crustal rather than a mantle environment.

Deep-sea glasses probably provide a rare gas inventory produced in a mantle environment and not greatly modified by crustal contamination. If a suite of such samples can be found with $^4He_r/^{136}Xe_f$ closer to the production ratio, useful limits to the mantle K/U ratio may yet be provided. If, on the other hand, we are able to specify the mantle K/U ratio independently, then measurements of the ratios $^4He_r/^{40}Ar_r$ and $^4He_r/^{136}Xe_f$ may provide a quantitative estimate of the magmatic mass fractionation process. The mantle components of all the rare gases (and of other volatiles) may then be realistically estimated from their measured abundances in deep-sea glasses.

Refractory element fractionations among carbonaceous chondrite groups

Gregory W. Kallemeyn & John T. Wasson

Institute of Geophysics and Planetary Physics, Department of Earth and Space Sciences, Department of Chemistry, University of California, Los Angeles, California 90024

Chondritic meteorites consist of collections of grains formed in the solar nebula. Chondritic materials can often be resolved into components that formed in differing nebular conditions. Carbonaceous chondrites are often accorded special significance in planetary models, especially because abundances of most elements in the CI group are indistinguishable from those in the Sun. Abundances of refractory lithophiles are among the most useful parameters for the classification of chrondrites, because they systematically decrease through the sequence carbonaceous→ordinary→enstatite[1,2]. They are also the most general parameter linking groups of very similar chondrites into clans which consist of groups having certain common properties that may indicate formation within a narrow range of distances from the Sun[3]. We report here newly discovered differences in refractory abundances among the different groups of carbonaceous chondrites.

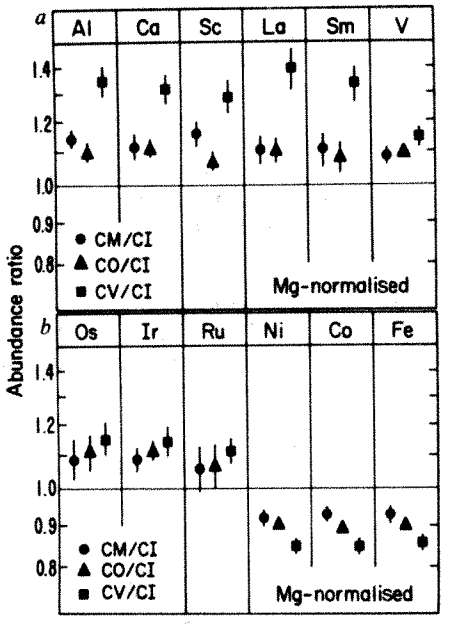

Fig. 1 Mean CI-normalised atomic abundance ratios for; *a*, refractory lithophiles; and *b*, refractory and non-volatile siderophiles. Uncertainty limits are 80% confidence limits. Our CI abundances (Mg normalised, Mg = 100) are: Al = 8.16, Ca = 5.87, Fe = 82.4, Co = 0.219, Ni = 4.48, Sc = 3.26×10^{-3}, V = 2.78×10^{-4}, La = 4.17×10^{-5}, Sm = 2.40×10^{-5}, Ru = 1.69×10^{-5}, Os = 6.34×10^{-5}, Ir = 5.49×10^{-5}.

Carbonaceous chondrites are divided into four groups, CI (high volatile abundances, no chondrules), CM (intermediate volatile abundances, small (~0.2 mm) chondrules), CO (low volatile abundances, small chondrules) and CV (low volatile abundances, large (~1 mm) chondrules). CV and CO chondrites were thought to belong to the same group, until Van Schmus[4,5] pointed out textural differences and McCarthy and Ahrens[6] found higher refractory lithophile abundances in CV than in CO. In the past it was believed that refractory lithophile abundances are indistinguishable in CI, CM and CO (refs 4, 5), and refractory siderophiles indistinguishable in all four carbonaceous groups[7,8]. In fact, our neutron activation data show that the carbonaceous groups can be divided into CI, CM–CO and CV clans based on differences in refractory lithophile abundances, and that refractory siderophiles do not parallel refractory lithophiles.

Nineteen carbonaceous chondrites were analysed: two CI chondrites (Orgueil, Alais), nine CM chondrites (Murray, Murchison, Mighei, Nogoya, Santa Cruz, Cold Bokkeveld, Yamato 74662, Cochabamba, Allan Hills A77306), five CO chondrites (Lancé, Felix, Ornans, Kainsaz, Warrenton) and three CV chondrites (Allende, Mokoia, Vigarano). Two samples (~300 mg each) of each meteorite were analysed in separate irradiations, with the exception of Orgueil (four samples), Allende (six samples), Santa Cruz (one sample) and Allan Hills A77306 (one sample). Among the elemental concentrations determined were several refractory lithophiles (Ca, Al, Sc, La, Sm), refractory siderophiles (Os, Ir, Ru) and a suitable normalising element (Mg). Complete data for some 25 elements will be published elsewhere.

The common practice of combining elemental concentration data from sources that may include systematic biases can unduly 'broaden' the abundance ranges. One such bias can result from the variable state of hydration of CI and CM chondrites. Producing our own large data base for each carbonaceous chondrite group and determining a suitable normalising element in the same sample enabled us to avoid these problems and has resulted in a clearer picture of elemental abundance variations among the different groups.

Refractory lithophile abundances in CM, CO and CV chondrites relative to CI are plotted in Fig. 1*a*. The data are Mg-normalised as we do not determine Si. Normalising to Si would not noticeably change the plots, as the Mg/Si atom ratio is essentially identical for CI, CM and CO and at most 3% higher for CV[6]. Our results confirm the observation[6] that CV refractory lithophile abundances are considerably higher (~×1.34) than those in CI. The higher abundance of refractories in CV chondrites may result from an enhancement of the large refractory inclusions present in this group relative to the other components (matrix and chondrules) carrying the major lithophiles Si and Mg. The higher abundance of refractory inclusions is attributed to differential settling of grains to the median nebular plane[9], with the rate of settling being proportional to the density and radius of the grains. At the median plane grains could agglomerate to planetesimals by gravitational collapse[9,10]. Mg concentrations in the refractory inclusions in Allende are lower than those in the whole rock; V concentrations[11,12] are higher, but inclusion/CI ratios are only about half as high as values found for highly refractory elements[12,13], thus accounting for the lower CV enhancement (×1.14) of V.

Our most unexpected discovery was that CM and CO refractory lithophile abundances are distinctly higher, by ~1.12 and ~1.09, respectively, than those in CI chondrites. Oxygen isotope data[14] are not inconsistent with an interpretation that the ~10% difference in refractory contents between CM–CO and CI indicate formation at different nebular locations. CI chondrites and CM matrix scatter along fractionation lines differing about 3% in $^{17}O/^{16}O$ ratio when extrapolated to the same $^{18}O/^{16}O$ ratio. The CI results are whole rock data and probably reflect equilibration with nebular gases. It may be that the CM data result from equilibration inside a parent body, but if they also reflect nebular equilibration, the differing O isotope compositions indicate different formation locations for CM and CI.

The rare refractory-rich inclusions in CM and CO chondrites[15–17] are smaller (~0.1 mm) than those typical of CV chondrites (~1 mm). As refractory inclusions are unknown in CI chondrites, the presence of these in CM and CO could possibly account for the small refractory lithophile enrichment. McSween[18] reports that anhydrous inclusions are about 2.5 times more abundant in CO than CM chondrites. If the refractory fraction of anhydrous materials is the same in each group and our simple model is correct, the abundance of refractory-rich materials should be about the same in CM and CO. However, CM refractory inclusions apparently have higher refractory contents than CO inclusions[17], and part of the

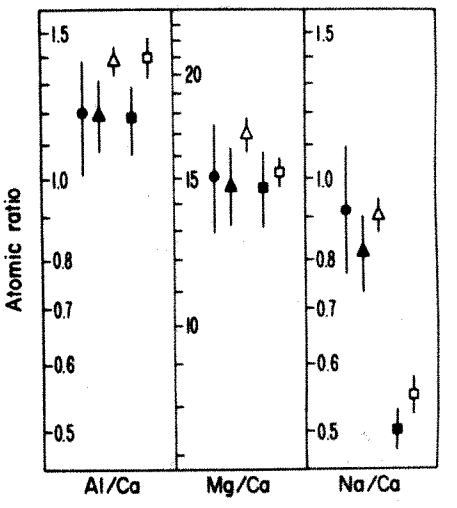

Fig. 2 Element/Ca ratios for CI and CM carbonaceous chondrites and the Sun from this work (△, CI; □, CM) and from compilations of Holweger[24] (●, solar; ▲, CI; ■ CM). Our CM Mg/Ca ratio is closer to the solar ratio than our CI value, but our Na/Ca value, like Holweger's is much lower than the reported solar ratio.

discrepancy may also have resulted from aqueous alteration and destruction of some CM inclusions[18,19].

It thus seems best to divide the carbonaceous chondrites into three separate clans: CI, CM–CO and CV chondrites. The refractory lithophile data are inconsistent with the formation of CI, CM and CO chondrites from two rigidly defined components (matrix + anhydrous minerals including chondrules)[20].

Figure 1*b* shows Mg-normalised refractory siderophile abundances for CM, CO and CV relative to CI. Also plotted are the siderophiles Fe, Ni and Co that are neither refractory or volatile. Refractory siderophiles are 1.06 to 1.15 times higher in CM, CO and CV than in CI. Previous analyses[7,8] have not revealed this enrichment, perhaps partly as a result of the lack of internal normalisation and partly by the sometimes seemingly arbitrary selection of mean CI concentrations. Morgan and Lovering[21] did note a small enhancement of Os and Re in CM relative to CI but attributed it to probable sampling errors. Refractory siderophile abundance ratios seem to decrease as CV > CO > CM. In each group Os and Ir ratios are about the same whereas Ru values are slightly smaller. This may be related to the fact that Ru is less refractory[22]. Relative to Os and Ir, CI-normalised Ru is less abundant in one refractory inclusion[13] and in 50 metal particles from another inclusion[23] of the Allende CV chondrite. Excluding Ru, abundance ratios of the refractory siderophiles in CM and CO chondrites are approximately the same as those of refractory lithophiles within analytical error, whereas in CV refractory siderophiles are about 15% lower than refractory lithophiles.

Refractory siderophiles are on average less abundant than refractory lithophiles in type B and coarse-grained refractory inclusions from Allende[24], and the siderophile/lithophile ratio is still lower in fine-grained inclusions. This suggests why refractory siderophiles are not as enriched as refractory lithophiles in CV chondrites. If a significant fraction of the refractory siderophiles was present in other kinds of carrier grains, these grains may also have been the dominant carriers of the common siderophiles (Fe, Co, Ni) that are nearly 15% deficient in CV relative to CI (Fig. 1*b*). We recently analysed a fine-grained chondritic inclusion from Allende[25] and found it to be enriched in refractory and common siderophiles, but depleted in refractory lithophiles relative to CV chondrites. The inefficient settling to the nebular midplane of similar fine-grained material could account for the observed siderophile/lithophile fractionation at the CV formation location.

On the other hand, the lower abundance ratios of Fe, Ni and Co in CM (×0.93) and CO (×0.90) relative to CI is not paralleled by a resolvable decrease in the abundance of refractory siderophiles relative to refractory lithophiles, suggesting that the carrier of the lost Fe, Ni and Co in CM and CO chondrites must have had much lower refractory siderophile/Ni ratios than the siderophile carrier lost during the formation of CV chondrites. Thus the carriers of both refractory siderophiles and refractory lithophiles were different at the CV location from those at the CM–CO location.

The actual nebular processes were probably more complex than those outlined here. Instead of two (one refractory, one nonrefractory) lithophile and two siderophile components there was probably a continuum of compositions which we have roughly approximated by a four-component model. It would seem that the four groups of carbonaceous chondrites are not as closely and as simply related as earlier thought, but are distinguished by chemical and isotopic fractionations suggesting their formation in differing conditions, and probably at differing distances from the Sun.

Recently, Holweger[26] examined the compositional relationship between the solar photosphere and chondrites to determine which chondrite group best approximated the solar composition. His work included five elements (Na, Mg, Al, S, Ca) determined to precisions of about ±10% in the Sun. Because of our improved data base, and because some chondrites were incorrectly classified in Holweger's data source, it seemed worthwhile to repeat the comparison. We do not analyse for S, so it is not included. In Fig. 2 Holweger's CI, CM and solar ratios of Al, Mg and Na to Ca are compared with our chondrite data. Our Al/Ca ratios are higher than Holweger's, but agree well with X-ray fluorescence data[6]. Holweger's conclusion that CI chondrites closely resemble the solar composition is also supported by our data. All CI, CM and solar ratios for non-volatiles agree within experimental error, but the CM ratio for the volatile Na is almost half the reported solar ratio. However, some other chondrite groups have higher Na abundances approaching CI values, and accurate solar data on additional volatile elements are needed before the CI–solar congruence can be verified.

Radiocarbon dating evidence on the impact of atmospheric pollution on upland peats

F. M. Chambers*, P. Q. Dresser & A. G. Smith

Department of Plant Science, University College, PO Box 78, Cardiff, UK

When radiocarbon dating is applied to young sample materials, the results are subject to the Suess effect[1]: that is, the concentration of atmospheric ^{14}C has been diluted by carbon dioxide containing negligible ^{14}C from the burning of fossil fuels since the onset of the industrial revolution. As this carbon dioxide is incorporated into growing plants in the normal manner, radiocarbon dating of young plant material tends to produce spuriously old dates. The age discrepancy could, in theory, be as much as 250 yr (ref. 2). However, during a study into the age, origin and vegetational history of upland blanket peats in South Wales, substantially older dates were obtained from recent horizons. The dating of different peat fractions by radiocarbon assay suggested that the substantially older dates derived from contamination by particulate pollution during the industrial revolution. The scale and impact of this pollution are discussed in the context of these results.

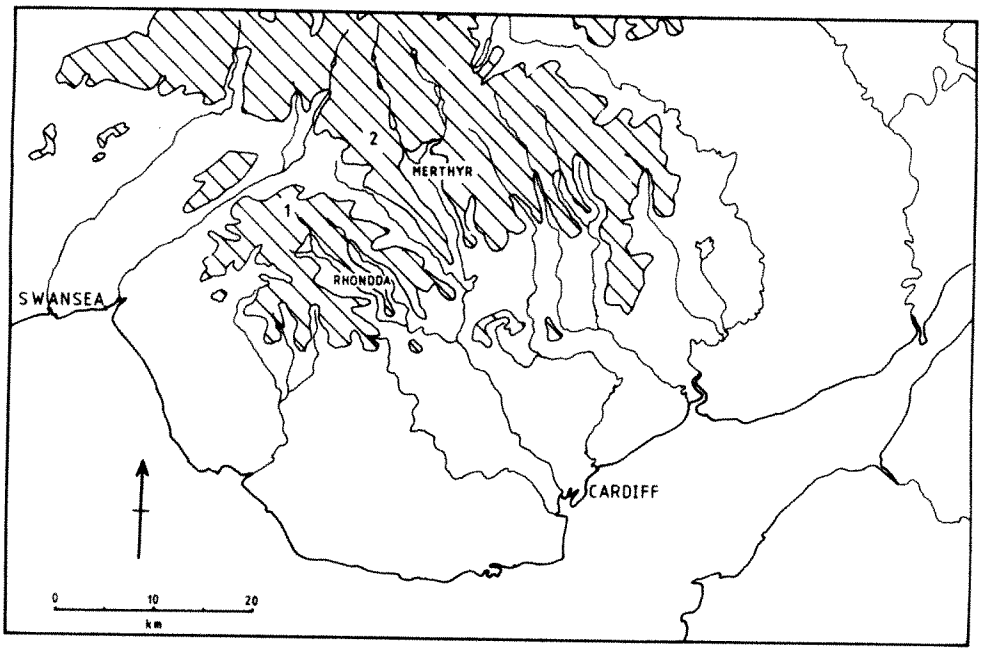

Fig. 1 Location of sites on map of South Wales: 1, Cefn Ffordd; 2, Coed Taf. Land over 300 m OD shown.

The blanket peats of upland South Wales are widespread and often shallow. Two profiles with less than 40 cm peat accumulation were investigated by pollen analysis, the sites being in close proximity to the industrial Rhondda and Merthyr valleys: Cefn Ffordd (SN 906032, 600 m OD) and Coed Taf (SN 988108, ~400 m OD) (see Fig. 1). In pollen diagrams from both sites, pollen spectra in the upper horizons showed a distinct change from those characterised by high Ericaceae values (mainly *Calluna vulgaris*—heather or ling) to a pronounced dominance of Gramineae (grass) pollen (Fig. 2). This seemed to record a shift from Callunetum to the present vegetation in which *Molinia caerulea* (purple moor grass) is dominant (Cefn Ffordd s now afforested with spruce). To date this and other changes, peat samples were prepared for radiocarbon dating using a pretreatment designed to remove those components likely to give an underestimate of the true radiocarbon age of the peat. The potentially more mobile 'humic acid' fraction was extracted in two alkali washes, and contamination from modern rootlets was minimised by passing the sample through a 250-μm mesh sieve. Dates were obtained on the resultant fine particulate fraction (F) as Dresser[3] had previously found this gave the most reliable estimate of the true radiocarbon age of blanket peat samples.

The pretreated samples were burnt, and after purification, the resultant carbon dioxide was mixed with hydrogen, passed over a ruthenium catalyst and converted into methane. The ^{14}C activity of the methane was measured at a pressure of 2.5 bar in a conventional 2-l copper gas proportional counter which was surrounded by a multi-anode anticoincidence counter and 8 ton of pre-nuclear age steel. Quoted precisions of the dates are one standard deviation and derive mainly from counting statistics.

The accumulation rate of blanket peats is variable[4]: at depth, the rate may be of the order of 50–100 yr cm^{-1}, but towards the surface where autocompaction is not as intense and the peat less humified, the accumulation rate may seem greater. Microscopic examination of the Cefn Ffordd profile revealed particles of coal dust in the upper 2 cm thought to correspond with modern coalmining. From these two lines of evidence a rough estimate of 100–250 yr BP was made for the inferred heather moorland–grassland transition. However, the radiocarbon date for a sample at 4–5 cm was 2,970 ± 50 yr BP (CAR-47), some 2,000 yr older than a sample from 8 to 10 cm which was dated to 925 ± 45 yr BP (CAR-106).

Samples from the Coed Taf site were dated subsequently using the same pretreatment. In the upper 2 cm, particles akin to soot were detected but no coal dust was observed. A date of 140 ± 50 yr BP (CAR-81; 1,810 ± 50 yr AD (ref. 5)) was obtained for a sample at 11–13 cm, which strongly suggested that the peat of a sample at 6–8 cm would have accumulated after the start of the industrial revolution in Wales. The radiocarbon age of this sample was 3,710 ± 90 yr BP (CAR-82F).

Thus at two sites, 11-km apart, upper horizons of peat produced radiocarbon dates that were apparently too old. Both samples pre-date similar changes in pollen spectra from which one might infer a similar vegetational change.

These old dates needed to be explained. Both were checked. Laboratory contamination could almost certainly be ruled out as contamination during pretreatment would be more likely to introduce modern (more radioactive) than older carbon.

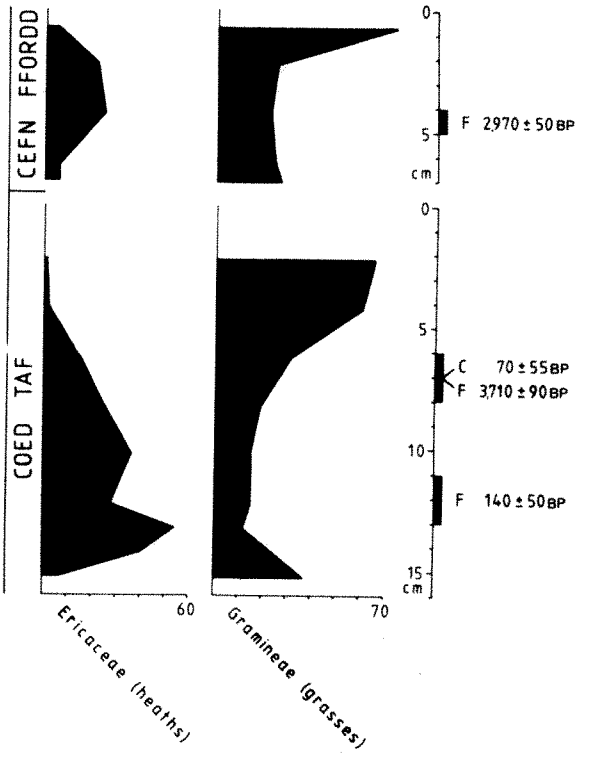

Fig. 2 Ericaceae and Gramineae curves (percentage total land pollen) for surface horizons of Cefn Ffordd and Coed Taf. Radiocarbon dates on humic acid (C) and fine particulate (F) fractions shown. For laboratory code numbers, see text.

Contamination during peat accumulation by material derived from older layers must, however, be considered. Eroding peat can be redeposited by water or wind. Either explanation is improbable because: (1) gross contamination from older peats would have been required to produce dates so old. Redeposition on this scale can be fairly easily recognised in the field but was not observed at either site. (2) Even the basal peat at Coed Taf is markedly younger than the date obtained for the fine particulate material at 6–8 cm. (3) Both sites were deliberately selected as being on convexities where inwash would be minimal. (4) There seem to be no recently eroded areas nearby that could have produced either windblown or waterborne organic material.

The incorporation of ancient carbon into a sample would dilute the activity of contemporary carbon, but there was no visual evidence of coal dust within the horizons dated. Although soot was used as a fertiliser during the nineteenth century, this seems to have been restricted to areas of market gardening or for improving heavy clay soils; its use on moorland in South Wales is not mentioned by Osborne[6]. Incompletely burnt fossil fuel (such as smoke and smut), carried up above the industrial valleys and deposited or rained out onto the moorland[7], seemed to be the only feasible source of old carbon.

This hypothesis was tested by dating the humic acid component of the 6–8-cm sample from Coed Taf. If the peat were as old as the F-fraction date had suggested, then the humic acid (C-fraction) would be expected to be of comparable age, or slightly younger[3,8]. The date obtained was considerably younger at 70 ± 55 yr BP (CAR-82C). This result could be obtained only from organic material produced after the start of the industrial revolution.

The implications of these results may now be considered.

(1) Atmospheric pollution produced by the substantially increased exploitation of coal during the industrial revolution has been incorporated in these South Wales upland peats. The discovery of this by radiocarbon dating enables some quantitative estimate of the scale of pollution to be made. Carbon from coal contains no detectable ^{14}C. In order for the fine particles of true age 100 yr BP to produce such old ^{14}C dates, more than 30% contamination of the organic carbon fraction by inactive carbon would be required. Assuming the apparent increase in age was due to the incorporation of inactive carbon, this would seem to comprise $36.4 \pm 0.8\%$ of the carbon content of the fine fraction of the Coed Taf 6–8-cm sample. Based on data from the combustion of the F-fraction in the dating process, and assuming that all the inert carbon was contained in this component, the original (untreated) peat sample contained 0.83 ± 0.01 g inactive carbon. This sample had an area of ~ 64 cm^2 and was accumulated over ~ 32 yr (based on the peat accumulation rate). These figures indicate there was an inactive carbon deposition rate of the order of 4 g yr^{-1} m^{-2}. (The original work did not envisage this type of treatment, but a subjective appraisal of the errors involved indicates an error of ± 2 g yr^{-1} m^{-2}.). The Cefn Ffordd inactive carbon deposition rate was of the order of 2.5 g yr^{-1} m^{-2}.

(2) In the radiocarbon dating of recent moorland vegetational changes near industrial areas, the use of unpretreated peat, or certain components, is likely to produce an erroneous result. Further research is still required, however, to ascertain the reliability of dates on the humic acid fraction as this component of blanket peats has already been shown to yield dates which are slightly too young[8].

(3) The transition from heather moorland to *Molinia* moor seems to have taken place at the two sites after the start of the industrial revolution. Did, then, changing moorland management practices associated with disrupted traditional employment patterns bring about such a marked vegetational change, or was the recent degeneration of heather moorland in some way connected with airborne pollution? Conway was inclined to discount the influence of atmospheric pollution on Pennine bogs[9], but the scale may not have been fully appreciated: deposition of some 0.6–1.8 ton per hectare inactive carbon over a 30-yr time-span is indicated for these South Wales moorlands. These figures convert to between 5.5 and 16.5 mg m^{-2} d^{-1} when expressed in the form used for modern deposit-gauge observations on undissolved deposits and ash yields[10].

Research was carried out during the tenure (F.M.C.) of a NERC studentship which is gratefully acknowleged.

Agnathans from the Devonian of China

L. B. Halstead

Department of Geology, University of Reading, Reading, UK

Y.-H. Liu

Institute of Vertebrate Palaeontology and Palaeoanthropology, Peking

K. P'an

Museum of Geology, Peking, China

Our Anglo-Chinese re-examination of material from southern China has led to a reappraisal of the two major groups of the primitive armoured jawless fish, the ostracoderms. We have united the galeaspids and polybranchiaspids in the Galeaspida of equal rank to the Osteostraci (Cephalaspides) and grouped them within the same major agnathan division as the anaspids and lampreys—the Cephalaspidomorphi. We also now believe that during the Lower Devonian, southern China was part of an isolated faunal province in which the agnathans experienced a major evolutionary radiation, independently from the rest of the world.

Fossil agnathans were first listed from southern China in 1937 by Ting and Wang[1] and, during the International Geological Congress in 1948, Young[2] reported rich deposits of Devonian vertebrates containing the agnathan *Cephalaspis*. This material was never described and its whereabouts are unknown. However, work in the same area in the same horizons in the early 1960s yielded several unusual forms[3]. The new genera *Galeaspis* (Fig. 1) and *Nanpanaspis* (Fig. 3*b*) were assigned to the Osteostraci (Cephalaspides), while *Polybranchiaspis* (Fig. 2) was placed in the Heterostraci (Pteraspides).

These fossils were unlike any previously described agnathans and their relationships to the known major groupings became a subject of controversy. It was suggested that they represented a new group of Agnatha to which the name Galeaspida was given[4,5]. This view received support from Stensiö[6] and Janvier[7] but was rejected by Miles[8]. Novitskaya[9,10] considered that the polybranchiaspids possessed a combination of osteostracan and heterostracan features and hence concluded that there was "no complete morphological break" between these two groups.

In the 1970s many new agnathan genera were described[11–14], including *Laxaspis*, *Sanqiaspis*, *Huanaspis*, *Asiaspis* and *Lungmenshanaspis* (Fig. 3), all of which were classified with the heterostracans. P'an[13] erected a new order of Heterostraci, on the basis of fragmentary remains of the genus *Hanyangaspis*. (This genus has been restudied and two of us (L.B.H. and Y.-H.L.) consider that it can be interpreted as a polybranchiaspid[15].)

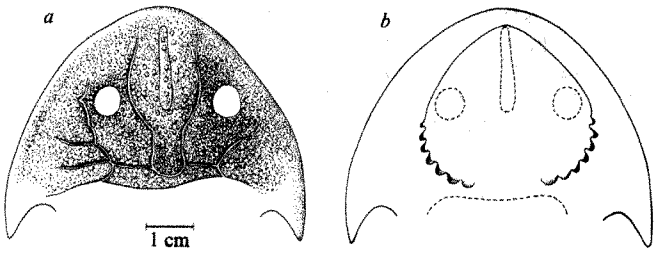

Fig. 1 Restoration of *Galeaspis* based on holotypes of *G. changi* Liu and *G. xujiachongensis* Liu. *a*, Dorsal view showing median dorsal opening, orbits, posterolateral spines and sensory canal system. *b*, Ventral view showing branchial openings and outline of buccal floor (IVPP, Peking).

P'an and Wang[14] identified the new genus (*Nakaolinaspis*) as a member of the amphiaspid heterostracans, a group confined to the Devonian of Siberia[16]. A restudy of this genus has convinced us that it was based on part of the skull roof of a specialised placoderm and hence there is no evidence that the amphiaspids are represented among the Chinese agnathans.

Southern China was clearly a province where agnathans underwent a major radiation. They were different from the familiar groups known from other parts of the world and their structure and relationships were controversial. We have re-examined the material in the Geology Museum and Institute of Vertebrate Palaeontology and Palaeoanthropology in Peking and reappraised the relationships.

The galeaspids (s.s.) and polybranchiaspids both possess a bony carapace covering the anterior part of the body, both dorsally and laterally. The lateral margin forms a longitudinal carina which extends on to the ventral surface and may be drawn out to form posteriorly or laterally directed spines. Similarly the anterior margin of the carapace forms an anterior ventral rim which is continuous with the lateral margin and may also be drawn out into an anterior projection or rostral spine.

The dorsal surface of the carapace is perforated by three openings—towards the anterior margin, a pair of circular openings which may be dorsally or laterally placed, and a median opening which may be transversely oval (*Polybranchiaspis*), circular (*Duyunaspis*), arcuate and transversely elongated (*Sanqiaspis*) or narrow and longitudinal (*Galeaspis*). On the inner surface of the armour there is a small round depression behind the dorsal median opening, which does not penetrate the carapace.

The inner margin of the ventral rim forms a smooth arc which runs posteriorly to the level of the paired circular perforations, behind which level the ventral rim at its median border forms a series of smooth notches. In some specimens small oval or circular plates are preserved adjacent to these notches and partially covering them.

The central median dorsal opening has a rim of fine ornament on its inner margin and in well preserved specimens the opening is raised somewhat above the general level of the rest of the carapace. In many specimens there is a well demarcated moat-like groove in front of the anterior margin of the opening. In a few specimens of *Polybranchiaspis* it can be seen that this opening was covered in life by an oval plate (Fig. 4). (Studies of photographs by J. A. Halstead and L.B.H. have revealed the presence of a similar plate in *Galeaspis*.) Behind the carapace in some specimens the squamation is preserved. On the ventral surface of the tail there are small diamond-shaped scales, the lateral scales are narrow and deep; in some forms there are dorsal ridge scales. There is no evidence of movable paired appendages and in *Sanqiaspis* it can be demonstrated that the tail was reversed heterocercal or hypocercal.

The sensory canal system comprises a similar pattern, as can be seen in Figs 1 and 2. The preservation is also comparable in both groups, in that the canals are enclosed within the armour. Frequently, as in *Polybranchiaspis*, they appear to lie in grooves on the surface, but in well preserved specimens they are covered by the superficial ornament (Figs 2 and 4*b*).

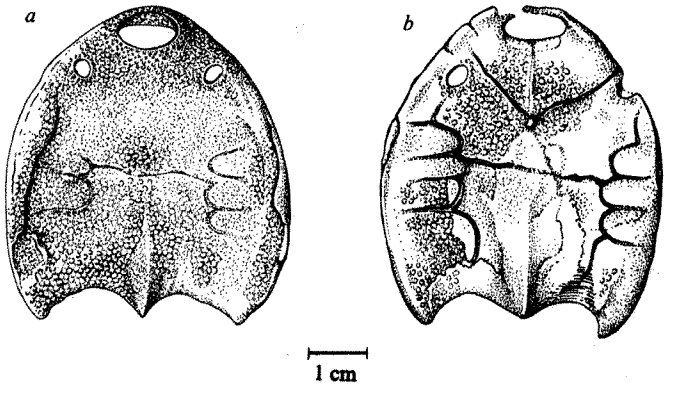

Fig. 2 *Polybranchiaspis liaojiaoshensis* Liu. *a*, Dorsal view showing median dorsal opening and dorsal orbits, with superficial ornamentation covering sensory canal system. *b*, Holotype, in dorsal view with outer surface removed to expose underlying sensory canal system (IVPP, Peking).

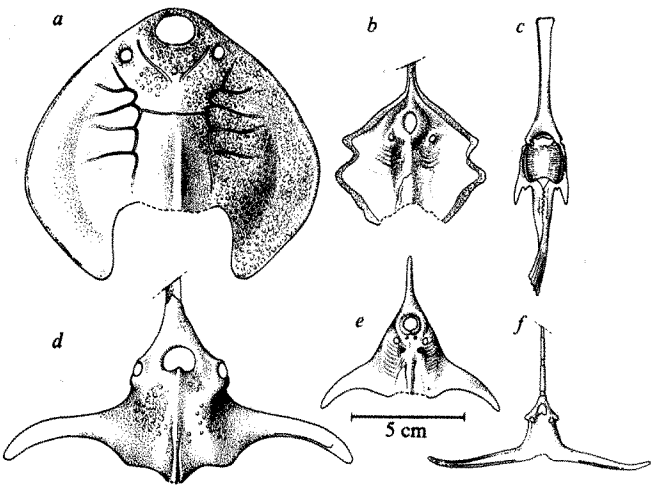

Fig. 3 Galeaspid genera in dorsal view to illustrate variety of external form. *a*, *Laxaspis* Liu; *b*, *Nanpanaspis* Liu; *c*, *Sanqiaspis* Liu; *d*, *Huanaspis* Liu (IVPP Peking); *e*, *Asiaspis* P'an; *f*, *Lungmenshanaspis* P'an and Wang (Geological Museum, Peking).

Many of the morphological features dealt with here have never been the subject of disagreement. It is universally accepted that the paired circular dorsal or lateral perforations of the carapace must be the orbits, while the small rounded depression, behind the dorsal median opening, is the position of the pineal organ. Similarly the notches on the median margin of the ventral part of the lateral extension of the dorsal carapace represent the individual openings of the gills or gill pouches.

The most controversial structure is the dorsal median opening, previously interpreted as a nasohypophyseal opening in *Galeaspis* and a mouth in *Polybranchiaspis*. The size of the opening seems to militate against it being nasohypophyseal, yet the position and profile seem inappropriate for a mouth. The discovery of a cover plate *in situ* in *Polybranchiaspis* and *Galeaspis* (Fig. 4) shows that it could not have functioned as a mouth and hence the inner margin of the ventral rim must have marked the anterior margin of the mouth, as in other agnathans such as cephalaspids and heterostracans. We suggest that the dorsal opening housed a sensory organ concerned with olfaction. There is no evidence as to whether this structure served as an inlet for water into the buccal cavity and hence to the gills, as a kind of analogue of the spiracle found in amphiaspid heterostracans and living skates and rays. Certainly for a benthonic

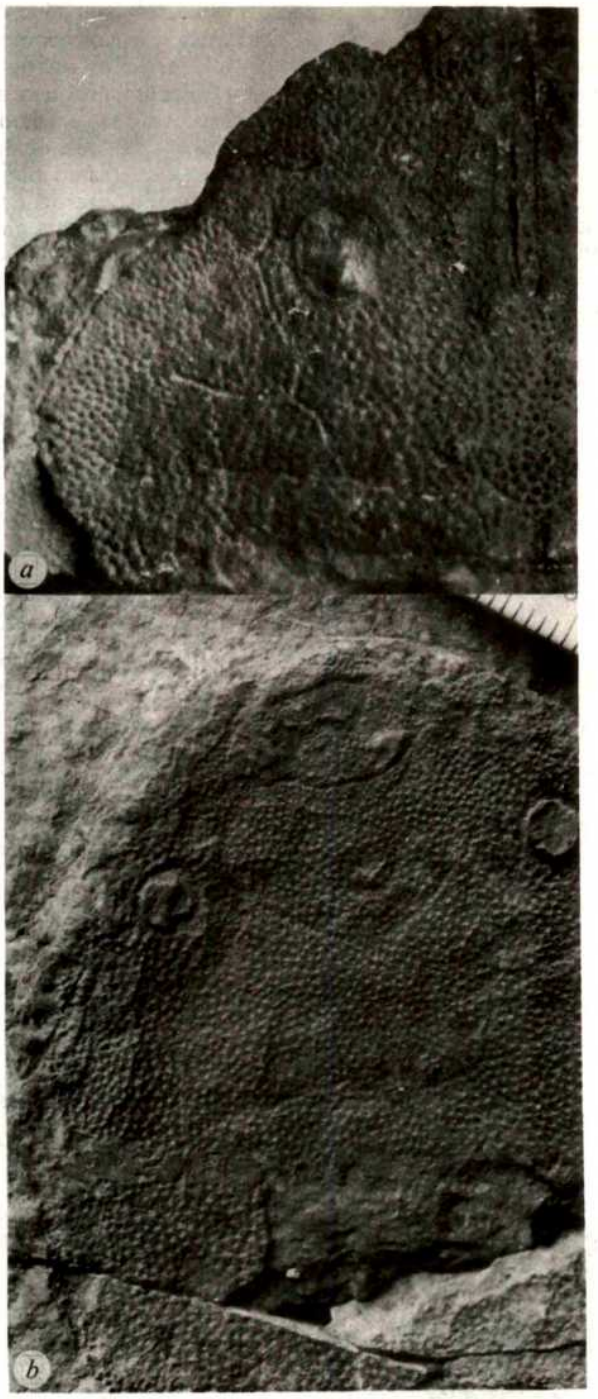

Fig. 4 *a*, *Galeaspis changi* Liu, holotype, dorsal view showing cover plate in position over median dorsal opening (IVPP, Peking). *b*, *Polybranchiaspis liaojiaoshensis* Liu, dorsal view showing cover plate in position over central median dorsal opening (IVPP, Peking).

microphagous feeder, it would make good functional sense for this opening to have served such a purpose.

From our examination of the morphology of the galeaspids (s.s.) and polybranchiaspids and the interpretations of the structures to which we have now been led, we agree that both groups can be united into a single major taxon of high rank, the Galeaspida, equivalent to Osteostraci and Anaspida.

The Galeaspida, Osteostraci and Anaspida all have three main dorsal openings, and separate gill openings. The first two groups have similarly preserved endocranial connective tissue[12,17]. Features which appear to link the Galeaspida with the Heterostraci include possible double nasal organs, a simple brain, a pineal body covered by the external armour and the overall shape of the carapace and hypocercal tail. These characters cannot be considered diagnostic as they are all primitive and in some cases would apply to such primitive cephalaspids as the trematapsids. The Chinese agnathans can be excluded from association with the heterostracans but they can be linked in a general way with the cephalaspids.

With the overall systematic position of the galeaspids agreed in the context of the known agnathan groups, it is evident that *Galeaspis* closely resembles the cephalaspids in having its gill openings arranged into a more or less circular pattern and also in having fewer gill openings than do the polybranchiaspids. The latter seem to be less specialised in this regard, with gills arranged serially along the anterior part of the body, although in the overall proportions of the carapace the polybranchiaspids vary greatly. The apparent similarity of *Galeaspis* to the cephalaspids, with the exception of the presence of lateral and posterior dorsal sensory fields, may indicate a degree of direct relationship or parallel evolution as the organisms become adapted for an ecological niche comparable to that occupied elsewhere by the cephalaspids.

The Galeaspida represent a unique major evolutionary radiation of the ostracoderms, which appears on present evidence to have been confined to the south China province. With the possible exception of the Silurian cyathaspid *Kiangsuaspis* described by P'an[18] there is no sign of any agnathan that can be linked to forms known from other parts of the world. The firm impression is that, as far as agnathans were concerned, this region was isolated during the Lower Devonian.

We acknowledge financial support from The Royal Society and the Geology Department and Research Board of the University of Reading (L.B.H.). The visit to Peking was made possible by the efforts of the late Professor C. C. Young and Dr (Mrs) Sun Ai-Lin to whom thanks are due. Specimens were drawn in Peking by Jennifer Halstead.

Internal anatomy of the polybranchiaspids (Agnatha, Galeaspida)

L. B. Halstead

Department of Geology, University of Reading, UK

A number of polybranchiaspids (Agnatha) from the Devonian of China have parts of their soft anatomy, including the central nervous and vascular systems, extremely well preserved as mineral replicas. This has made possible direct comparisons with the internal anatomy of the living agnathans, the hagfish and lampreys, as well as the fossil heterostracans and cephalaspids. The polybranchiaspids do not seem to be related to either the hagfish or the heterostracans, but instead represent a separate grouping, the Galeaspida, allied to the lampreys and cephalaspids.

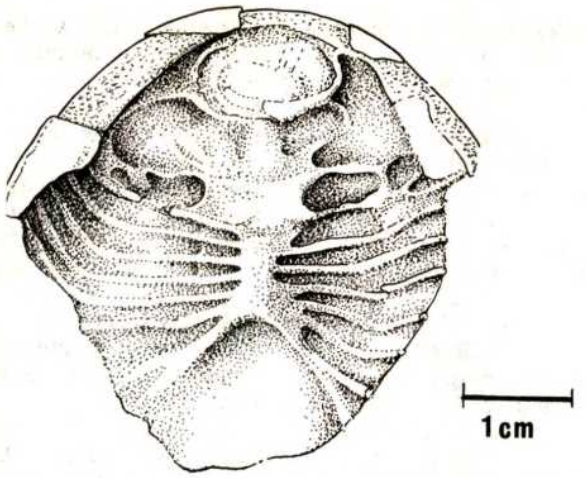

Fig. 1 *Polybranchiaspis liaojiaoshensis* Liu, V.3027, Institute of Vertebrate Palaeontology and Palaeoanthropology, Peking, internal view of perichondral ossification of endocranial tissue showing mouldings produced by orbital sinus and somites.

The anatomy of the polybranchiaspid carapace is now well known[1–4]. The neurocranial floor on the inner surface of the dorsal carapace of *Polybranchiaspis* (Fig. 1) was described by Liu[2]. Beneath the superficial ornamentation at the same level as the sensory canal system, there was a subaponeurotic (subcutaneous) vascular plexus (Fig. 2).

P'an and Wang[3] described several polybranchiaspid specimens, in particular *Duyunaspis*, in which after death the spaces occupied by the central nervous and vascular systems were filled by a secondary iron mineral and the bony material had dissolved away to leave a mineral replica of the internal anatomy (Fig. 3).

There are only two pairs of semi-circular canals in the ear, the anterior and posterior vertical, both with clearly defined ampullae. The two canals meet medially as the point where the utriculus is situated and from where it develops ventrolaterally. The sacculus, in contrast, is frequently expanded dorsomedially so that it comes to lie medial to the semi-circular canals. The round structure arising from beneath the canals and situated between them and the brain, is best interpreted as the sacculus.

The position of the orbits is in the region labelled 'premandibular elevation' by P'an and Wang[3]. The eyes are unlikely to be adjacent to the dorsal median opening but rather as in other polybranchiaspid genera[1–4]. The position of the nasal sacs is more difficult to decide. There is no justification for the positioning of the nasal sacs at the anterior margin of the specimen[3], a more likely position is immediately lateral to the dorsal median opening. There appears to be a nerve running from the forebrain region to this structure and, on this interpretation, this would be the olfactory nerve. The other possibility is the two structures immediately behind the dorsal median opening which P'an and Wang[3] identified as 'possible nasal lobes'.

The dorsal median opening is transversely oval but a posteriorly directed V at its posterior margin indicates a canal leading to the hypophysis, suggesting that the dorsal median cavity was a nasohypophyseal structure. There is no evidence as to whether this opened directly into the buccal cavity as in hagfish or was blind as in lampreys and cephalaspids.

The infilling of the endocranial cavity indicates the general configuration of the brain. The spinal cord with its accompanying spinal nerves expands anteriorly into the medulla oblongata, the major part of the hindbrain. There is no evidence of a transverse commissure representing the cerebellum or additional lobes relating to the development of the acousticolateralis system. The constriction lying at the junction of the anterior and posterior semi-circular canals of the ear was the position of the midbrain, even though in higher vertebrates it is always situated anterior to the ear region. In the polybranchiaspids, the pineal organ was sited at the level of the anterior semi-circular canals and therefore the midbrain must have been posterior to it.

The anterior part of the forebrain, the telencephalon, is either represented by the pair of irregular structures laterally or by the region lateral and deep to the pineal. In either interpretation, a degree of cranial flexure occurred as a consequence of the development of the median dorsal organ.

The identification of the cranial nerves that can be observed, presents considererable difficulties and hence must be considered tentative. The two cranial nerves seen on the right running obliquely posterolaterally were probably the different branches of the vagus X, and the nerve anterior to these but posterior to the ear region, the glossopharyngeal IX. Two nerves in close proximity running anterolaterally but diverging somewhat and approaching the brain beneath the semi-circular canals of the ear were the facial VII and trigeminal V nerves.

The most prominent feature of the vascular system was the pair of large calibre vessels running on either side of the labyrinth of the ear and the brain, the *vena capitis lateralis*[3] or lateral head vein, anteriorly ending in a large orbital sinus. Posteriorly there was the occipital venous sinus. It is not possible to determine with any certainty at which point the veins from the anterior and posterior parts of the body joined to form the common cardinal vein or *ductus Cuvieri* leading to the heart, and for this reason topographical terms are used. A series of segmental veins leading into the *vena capitis lateralis* are clearly preserved. Lateral to the occipital venous sinuses were further vessels draining segmental structures, paired dorsal aortae, from the efferent arterial system.

The most prominent aspect of the internal anatomy of the polybranchiaspids, observed in most genera[3,4] were a series of paired (up to 20 in number) dorsally positioned structures rising up on either side of the central nervous system, extending laterally some distance, and then curving posterolaterally and each associated with a separate branchial opening along the ventrolateral margin of the carapace. Such dorsal structures have been interpreted as representing the former position of gill

Fig. 2 *Polybranchiaspis liaojiaoshensis* Liu, portion of subaponeurotic (subcutaneous) vascular plexus and sensory canal system enclosed within the dermal armour.

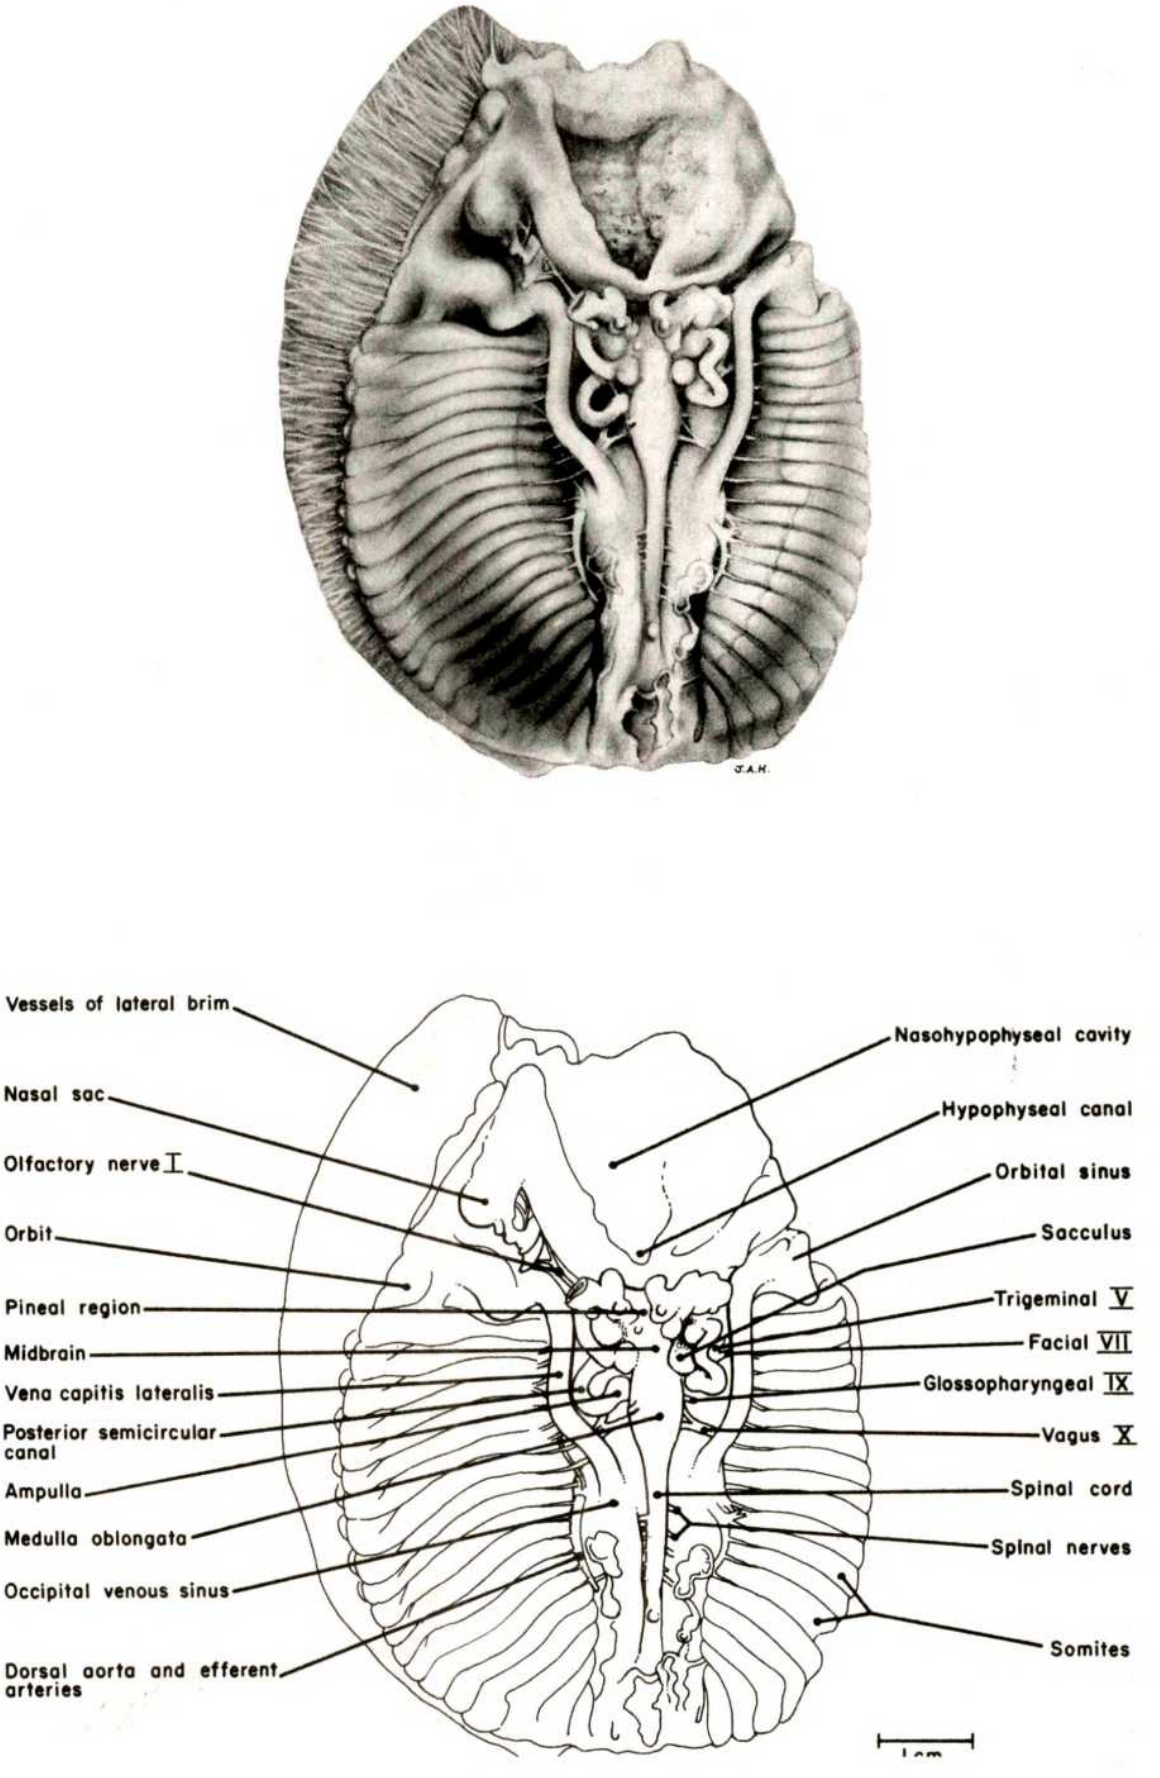

Fig. 3 *Duyunaspis paoyangensis* P'an and Wang, holotype, V.1324, Museum of Geology, Peking, in dorsal view showing mineral infilling of canals and spaces in endocranial connective tissue which have become exposed subsequent to the removal of the original calcified tissues. pouches[3,5], but also as somites or segmental muscle blocks[6,7]. The polybranchiaspids did not acquire their bony armour until they achieved their definitive size, hence it is necessary to postulate the existence, in the young stages, of serially arranged somites on either side of the central nervous system along the dorsal part of the head and trunk region.

These structures can be interpreted as segmental muscle blocks above the gill pouches, contributing to the pumping mechanism. The gills were unlikely to have been in direct contact with the dorsal armour; there would have been some somitic musculature intervening.

The preservation of the internal anatomy of the polybranchiaspids makes possible direct comparisons with living agnathans, the hagfish[8] and lampreys[9,10], as well as fossil, cephalaspids and heterostracans[6,7,11-14]. The living forms are characterised by their eel-like shape and absence of a bony external skeleton, scales or paired fins, all of which appear to have been secondarily lost. Several further features unite the two groups: a single external nasohypophyseal opening, paired olfactory lobes, pore-like gill openings, horny teeth on the tongue and the haemoglobin molecule made up of a single polypeptide chain (in contrast to the four of all higher vertebrates). Many of the differences are connected with their different modes of life. The hagfish is highly specialised in its reduction of sense organs, the eyes are reduced to the merest vestiges, there is no pineal organ and only a single canal in the ear, generally considered homologous to the posterior semicircular canal and a combined utriculus-sacculus element. The only feature that can be directly compared with that of the polybranchiaspids is the nasohypophyseal opening, which is terminal. The venous system of the hagfish, with its ventral cardinal 'heart' deep to the anterior cardinal sinus, is not comparable to the lateral head vein and occipital sinus of polybranchiaspids. The well developed eyes and ear regions and the configuration of the brain of the polybranchiaspids render hagfish affinities unlikely.

When the polybranchiaspids are compared with the lamprey, the similarities are striking: there is a dorsal median opening with a pineal organ behind. There are two semi-circular canals of the ear and the configuration of the brain is similar. The gill pouches each had separate openings to the exterior as in lampreys. In contrast, however, the polybranchiaspids appear to have paired nasal sacs and the pineal was covered by the bony armour. The details of the internal anatomy strongly indicate a close relationship to lampreys. The cephalaspids possessed the same basic similarities and differences with the polybranchiaspids as the lampreys, but show further similarities in the degree of endocranial ossification and in the venous system, which is comparable to that of the primitive cephalaspid *Trematapsis*. The polybranchiaspids were closely related to the cephalaspids, but can be excluded from them on account of their lack of dorsal and lateral sensory fields, the corresponding lobes of the hindbrain, the large dorsal median opening, covered pineal and paired nasal capsules.

Finally, the polybranchiaspids can be compared with the heterostracans, with which they have been generally associated. They are similar in possessing double nasal sacs and a covered pineal but differ in the endocranial ossification and separate gill openings. The recognition that the dorsal median opening was not a mouth, excludes the polybranchiaspids from the heterostracans[4].

The details of the internal anatomy confirm that the polybranchiaspids belong to an independent group, the Galeaspida, allied to lampreys and cephalaspids within the Cephalaspidomorphi division of the Agnatha.

Specimens were drawn in Peking by Jennifer Halstead.

Dioecious *Solanum* species of hermaphroditic origin is an example of a broad convergence

Gregory J. Anderson

Biological Sciences Group, University of Connecticut, Storrs, Connecticut 06268

Unlike the taxa in some genera which show a range of variability in floral morphology, species of *Solanum* deviate very little from the typical hermaphroditic flower. The known deviant taxa fall into two classes: most are andromonoecious (male and hermaphroditic flowers on the same plant), and the remaining few are androdioecious (male flowers on one plant, hermaphroditic flowers on another)[1]. I report here evidence for the first instance of a truly dioecious species of *Solanum*, a significant discovery in the light of the floral uniformity of this large (second only to *Senecio*) and economically important genus. The most closely related species and species groups comprise only hermaphroditic forms; this dioecious species is among the few non-hermaphroditic forms native to the New World, the area of greatest species diversity of the genus. Furthermore, as shown below, the species is characterised by a functionally, though not morphologically, dioecious condition. Finally, this demonstration that the two floral forms represent different sexes of the same species, rather than (as originally described) different species, impels closer analysis of other species pairs.

The plants studied were originally collected in mountainous regions of the states of Mexico and Michoacan in Mexico, and San Marcos in Guatemala. The specimens collected were identified using Correll's monograph[2] as *Solanum appendiculatum* and *Solanum inscendens*. These species are non-tuberous (although relatively closely related to the potato) woody perennials that grow to a length of 3-10 m up tree trunks and rock surfaces. The primary character used to separate these two species in keys is the length of the style in relation to the staminal column (short style, *S. appendiculatum*; long style, *S. inscendens*). When the initial collections were grown in greenhouses, seeds from each fruit collected produced both long style and short style plants. Subsequently, seed populations from 24 collections have been grown to generate the sex ratio given in Table 1 line (1). It is clear from ratios derived from populations of seeds collected in the field, and from a small artificially derived F_1 population (line 2), that the primary sex ratio is about two long (L-functional female, see below) to one short (S-functional male). However, the sex ratio derived from randomly selected populations in the field is nearer to 1 : 1. The latter ratio is closer to that usually reported for dioecious taxa[3-5]. At present, too little is known of the field biology of this *Solanum* taxon to speculate on which factors alter the primary sex ratio.

The relationship between the long- and short-style plants was assayed with crossing studies and with observations of pollen tube growth in styles. The results of these two analyses provide strong evidence that this species is functionally dioecious. More than 400 crosses were attempted among the four possible combinations of short- and long-styled flowers. The only successful combination involved L♀ and S♂ (Table 2). Seeds resulting from this combination were viable, and the mature F_1 offspring were fully fertile. Studies of pollen tube growth[6] add

Table 1 Features of the sex forms

Features	Long-style form L	Short-style form S
(1) Sex ratio (greenhouse)	2.02 (107)	1.0 (53)
(2) Sex ratio in a greenhouse F_1 population	1.75 (7)	1.0 (4)
(3) Sex ratio (field collections)	1.0 (23)	1.22 (28)
(4) Flowers per inflorescence	34.0 (30)	34.27 (30)
(5) Pollen grains per flower	82,750 (6)	129,465 (5)
(6) Pollen stainability	78.6% (119)	79.4% (77)
(7) % Pollen grains: inaperturate	100%	0%
tricolporate	0% (2,281 grains, 20 collections)	100% (2,587 grains, 25 collections)
(8) Ovules per ovary	11.26 (42)	11.28 (36)

The upper of the two sets of numbers represent averages, while the lower sets, in parentheses, represent sample sizes.

further confirmation that the L♀×S♂ combination is the only one functional. With a single exception, pollen tubes were produced only when pollen from short-style flowers was placed on stigmas of long-style flowers (Table 2). Virtually all other combinations, including attempts at self-pollination (columns *E* and *F*, Table 2), failed to yield pollen tubes. These data are also interesting in relation to the question of potential mechanisms responsible for crossing success. Perhaps crosses fail and no pollen tubes are produced because of chemical interactions between stigma and pollen, such as those involved in typical S-allele (incompatibility) systems[7]. Or perhaps, as implied below, the pollen from the long-style flowers is physically unable to germinate.

Analysis of field collections and greenhouse-grown plants indicates that both long- and short-style forms possess an equal number of flowers per inflorescence (Table 1, line 4). This 1:1 ratio for inflorescence size is incongruent with the usually larger inflorescences of males reported by Opler and Bawa[4] for dioecious tropical trees. There is, of course, no reason to expect that every species will follow the general pattern Opler and Bawa have described. Furthermore, because *Solanum* flowers reward potential pollinators with pollen rather than nectar[1], one could expect the female inflorescences to remain as large as the male and thus not suffer a reduced frequency of visits because of insufficient reward.

Although the sex ratio is not male biased and inflorescence sizes are the same, counts[8] of the number of pollen grains per flower (Table 1, line 5) in the two sex forms are significantly different. The short-style flowers bear greater than 55% more pollen grains. Perhaps the smaller quantity of pollen grains in the female flowers (though not so small as to reduce the frequency of visits by pollinators) is one manifestation of the selection for unisexuality. Although the quantity of pollen is less in the long-styled flowers, two tests of viability (aniline blue in lactophenol, acetocarmine) showed that both flower types produced equally stainable pollen (Table 1, line 6). However, such tests can only estimate viability and not whether pollen is actually functional. The data given here for crossing and pollen tube growth are one indication that the pollen from long-style flowers is not functional. Light and scanning electron microscope studies of acetolysed pollen give another. The long-style flowers always bear inaperturate grains and the short-style flowers the more typical tricolporate types[9]. The lack of development of colpae and pores in the pollen of the long-style form may be one of a suite of adaptations to functional femaleness. Inaperturate pollen, presumably quite functional, is reported from several families including the Solanaceae[10]. However, the data reported here seem to be a strong indication that while pollen from the long-style flowers may be a suitable reward for floral visitors, it is not otherwise involved in the reproductive process.

Except for the difference in style lengths, the gynoecium (stigma, style and ovary) shows few morphological modifications. Contrary to expectations, the short-style flowers bear as many ovules as the long-style flowers (Table 1, line 8). This seems a strong indication that the dioecy in this species is still in an early stage of evolution.

The discovery of a new breeding system in a genus as large and invariable for this feature as *Solanum* is unusual. The important point is that the long- and short-style flower forms do not represent two species which hybridise. Crosses in the right combinations can be made with ease, and the resultant F_1 plants are fully fertile. In addition, greenhouse populations consistently give a 2L(♀):1S(♂) segregation ratio. Furthermore, the data for crossing and pollen tube growth show clearly that this is not a case of heterostyly. This is in agreement with previous conclusions that true heterostyly is unknown in the Solanaceae[11]. Rather, the long- and short-style flowers are simply breeding morphs of a single dioecious taxon.

What evolutionary advantage the dioecious system confers on this taxon is perplexing. The usual explanation that dioecy arises in a self-compatible taxon as a way of ensuring outcrossing[3,12] is certainly possible. However, it is somewhat less likely here because most closely related species tested possess a well developed system enforcing obligate outcrossing[7,13]. Bawa and Opler[3] have argued that dioecy may be selected in hermaphroditic flowers in preference to outbreeding mechanisms such as S-alleles to enhance effective pollination. They argue that if the number of flowers on an individual is high, most pollination will involve transfer of ineffective self pollen. Such pollen could cover the stigmatic surface so that pollen brought from another plant may, although capable of it, be unable to effect pollination because stigmatic space is unavailable. This argument was proposed for tropical trees with a very large number of flowers. It may apply to the dioecious *Solanum* described here because it has larger inflorescences with more flowers open at any one time than most closely related species[2,13]. However, the fact that females bear anthers with pollen (although significantly less pollen) lessens the force of this argument for this species.

The dioecy described here is also of particular interest because there is no precedent for unusual sex forms in any of the closely related species groups[1]. Several authors[14,15] have argued that dioecious taxa frequently evolve from gynodioecious or less frequently androdioecious ancestors. Gynodioecious taxa are unknown in *Solanum*, and although androdioecious taxa have been reported, they are, like most species with unusual sex forms in the genus, native to the Old World and are placed in a different subgenus[1]. Thus the development of dioecy described here does not represent the culmination of a linear evolutionary

Table 2 Results from cross pollination and pollen tube studies

	Combinations *A* L♀×S♂	*B* S♀×L♂	*C* L♀×L♂*	*D* S♀×S♂*	*E* S self†	*F* L self†

series, but rather a broad convergence on a set of apparently advantageous breeding systems. Furthermore, Crowe[16] has suggested that most dioecious species evolved from monoecious (primarily) or heterostylous taxa; the lack of either of these conditions in *Solanum* precludes their application to this case. The fact that the separation of sexes is still only functional, and not morphological, very likely indicates a system in the early stages of evolutionary development. This situation provides a special opportunity which, as Crowe proposed[16], may lead to a better understanding of the origin and evolution of incompatibility mechanisms among the angiosperms in general.

I thank L. Mehrhoff for aid with field collections, W. Crepet, H. Krider and D. Levine for help with laboratory work, and M. Anderson, J. Silander and J. Slater for critically reading the manuscript. Length and evolutionary stability of food chains

Harold M. Hastings

Department of Mathematics, Hofstra University, Hempstead, New York 11550

Michael Conrad

Department of Computer Science and Biology, Wayne State University, Detroit, Michigan 48202

Grazing food chains in natural ecosystems tend to be relatively short, usually involving no more than four or five trophic levels[1–3]. Cohen[4] describes 19 food webs with a total of 102 top predators. Recent independent analyses of these data by Cohen[4] and Pimm (see ref. 5) show that most top predators occupy the third trophic level. However, as Slobodkin[3] has observed, "It is possible to conceive of predators that are small enough and ferocious enough to attempt to live off the top of a trophic pyramid, and thereby become a seventh, or even an eighth, trophic level. It is by no means clear why this situation has not occurred." Our answer, which we discuss here, incorporates energy transfer calculations introduced by Hutchinson[1] and Odum and Odum[2] within the framework of the evolutionarily stable strategy (ESS) developed by Maynard-Smith and Price[6,7]. We argue that food chains should collapse to the shortest possible length compatible with biochemical and physiological constraints. This minimal length is frequently three, and is largely independent of primary productivity.

Odum and Odum[2] consider the inefficiency of energy transfer. If each species can transmit only a fraction (usually between 5% and 20%) of its incoming energy to the next level, this sharply limits the length of food chains. Although any such limit scales as the logarithm of primary productivity, Pimm and Lawton[8] observe that 'food chains are not noticeably shorter in barren Arctic and Antarctic terrestrial ecosystems compared with a productive tropical savannah or the fish guilds of a tropical coral reef,' although primary productivity varies by a factor of 10^4. Hutchinson[2] proposes that pressure to increase predator efficiency could even shorten food chains. An efficient higher predator, with limited food supply, might eliminate his prey and be forced either to drop to a lower trophic level or to become extinct. Pimm and Lawton[8] propose a third explanation involving Lokta–Volterra dynamics (see refs 5, 9 for reviews). Our explanation considers the evolutionary stability of alternative trophic strategies. Trophic levels are defined by assigning plants the first trophic level, herbivores the second and primary carnivores the third. More generally, a species which feeds primarily on the nth trophic level is assigned the $(n+1)$st trophic level. The classical energy transfer argument states that lower trophic levels offer a richer thermodynamic environment (in terms of free energy) than do higher trophic levels. Following the analysis of optimal foraging and resource partitioning of MacArthur and Pianka[10], a predator's strategy may be described as optimal if the predator exploits the thermodynamically richest accessible environment. We shall argue that such optimal strategies are evolutionarily stable, whereas alternatives are not.

Consider a fourth-level species, one which feeds primarily on carnivores. Its nutritional needs could be satisfied at a lower trophic level by herbivores, as carnivores and herbivores are nutritionally interchangeable. In the absence of additional non-nutritive constraints, members of this species could always drop to a lower trophic level and compete with their former prey for the thermodynamically richer herbivore environment. As long as the marginal energy gain from feeding on herbivores is greater than feeding on carnivores, the ESS will be to concentrate on herbivores, but to feed on carnivores encountered in defence or competition. This assumption on energy gains is justified by the usual range of transfer efficiencies, and the probable greater unit costs of successfully attacking carnivores.

More precisely, let $h(t)$ be the energy gain from expending an effort t on feeding on herbivores. Similarly, let $c(t)$ be the gain from an effort t on carnivores. We assume that both $h(t)$ and $c(t)$

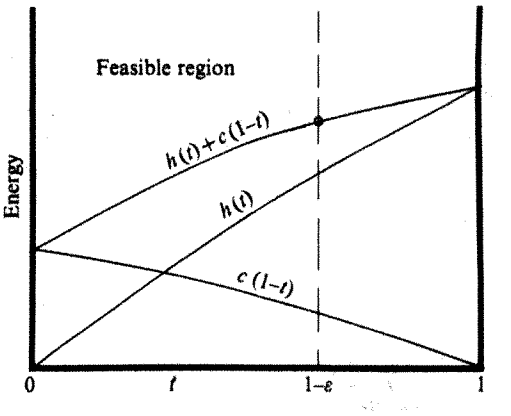

Fig. 1 The ESS of maximum feasible energy gain. The graph shows the net energy gain $h(t)+c(1-t)$ from a strategy of spending effort t on herbivores and $1-t$ on carnivores, its components $h(t)$ and $c(1-t)$ from herbivores and carnivores, and the required energy ε expended on feeding on carnivores. Thus, $0 \le t \le 1-\varepsilon$. The maximum energy gain occurs at $t=1-\varepsilon$ under our assumptions.

0028–0836/79/510838—02$01.00

© 1979 Macmillan Journals Ltd

are increasing functions, convex because of 'diminishing returns', and close to linear, and that $c(t) \ll h(t)$—the ratio $c(t)/h(t)$ represents an effective transfer efficiency. Now, consider a strategy of expending an effort t on feeding on herbivores and $1-t$ on feeding on carnivores. Here $0 \leq t \leq 1$. We seek to maximise the total energy gain $h(t)+c(1-t)$ subject to the constraint that the organism expend at least a small effort ε in competing with (and incidentally feeding on) potential carnivore prey. Many factors influence ε, including territorial behaviour, ability to flee and population density. As long as

$$\left.\frac{dh(\tau)}{d\tau}\right|_{\tau=t} > \left.\frac{dc(\tau)}{d\tau}\right|_{\tau=1-t}$$

or simply, $h'(t) > c'(1-t)$, for $0 \leq t \leq 1-\varepsilon$, this maximum will occur at $t = 1-\varepsilon$ (Fig. 1). Therefore, from the above assumptions, if relatively little energy ε need be expended for competition, such an organism should adopt the ESS of concentrating (spending effort $1-\varepsilon$) on herbivores.

The option of switching to a lower trophic level is not available to first-level carnivores because of nutritional differences between plants and herbivores; herbivores clearly face far stricter constraints. Furthermore, these nutritional requirements arise from synthetic and degradative specialisations which are selectively advantageous. However, a parasite may be subject to different dynamics, and not always select the most numerous host because its host constitutes its entire thermodynamic and spatial environment, and is not a potential competitor under alternative trophic strategies. Thus, on the spatial scale of an individual parasite[6,7], a herbivore host might offer no advantages over a carnivore. It is also conceivable, but energetically unlikely, that diminishing returns could make $h'(t_*) = c'(1-t_*)$ for some $t_* < 1-\varepsilon$. This yields a mixed strategy[6,7], with effort t_* expended on herbivores and $1-t_*$ on carnivores. Finally, the case of concave $h(t)$or $c(t)$ is also energetically unlikely.

We have shown that in the absence of non-nutritive constraints, grazing food chains should evolve towards the evolutionarily stable length of three. Parasitism and opportunistic feeding allow for some chain lengthening. Longer chains may also exist transiently, possibly being relatively long-lived, or may persist due to special constraints such as size and habitat compatibility of predator and prey. Differences in nutritional value of predators and prey are unlikely to be as significant for protista as for metazoans, but size constrains may be more important. These factors are independent of primary productivity. Further, our argument that optimal foraging subject to biochemical and physiological constraints is an ESS applies to all trophic levels and strategies, independently of the detailed structure of the food web. We therefore predict that the length of food chains will be relatively constant over wide ranges in primary productivity. This agrees well with field data[4,5].

We thank Drs John Glasser, Gary Harrison, Robert May and Bernard Patten for helpful conversations. We acknowledge partial support from NSF grant MCS77-01628 (H.M.H) and a visiting appointment in the Department of Mathematics and Institute of Ecology at the University of Georgia (H.M.H.) during which this research was done.

Male lions in large coalitions gain reproductive advantages

J. David Bygott*, Brian C. R. Bertram† & Jeannette P. Hanby*

* Sub-Department of Animal Behaviour, Madingley, Cambridge, UK
† Research Centre, King's College, Cambridge, UK

Cooperation between two or more individuals has been shown to yield short-term benefits in several vertebrate species[1–4], and various hypotheses have been developed to explain the evolution of cooperative behaviour[5–7]. However, until now there has been no evidence to show that such cooperation actually does confer lifetime's reproductive advantages on more than one member of the coalitions concerned[8,9]. Long-term studies of wild lions (*Panthera leo* L.) have now provided such evidence. We show that, compared with singletons and pairs, male lions in groups of three or more can more reliably gain tenure of female prides, retain tenure for longer, mate with more different females, and produce more surviving offspring; thus each individual has higher fitness through cooperation.

Lions were observed in the Serengeti National Park and in the adjacent Ngorongoro Conservation Area, Tanzania, in 1966–69 by G. B. Schaller[2]; in 1969–73 by B.C.R.B.[10,11]; and in 1974–78 by J.D.B. and J.P.H.[12]. Observations on the same prides in comparable habitats were spread over periods of 3–12 years. All members of these prides were known individually by natural markings[13].

A lion pride is a matrilocal group of 2–18 (mean 6)[2,12,14] genetically related females, plus their cubs. Young male lions usually leave their natal pride as a group of relatives shortly before sexual maturity. Then, as a coalition, they gain and retain sole possession of a pride for a variable period, excluding rival male groups. The male group's tenure, and therefore its effective reproductive life[10], typically ends when they are displaced from their pride and their area by a new group of males. Here we compare aspects of the reproductive success of the male groups of different sizes.

Table 1 The frequency of male lion groups of different sizes, and the probability that they will have tenure of a pride of lionesses

No. of males in group	No. of male groups: Total	No. of male groups: No. which had tenure	Probability of having tenure	Significance of difference
1	23	4	17.4%	
2	39	23	59.0%	<0.01
3	12	11	91.7%	<0.01
4	4	4	100.0%	
5	1	1	100.0%	
6	3	3	100.0%	
7	1	1	100.0%	

Total 183 adult males (that is, ≥4 yrs old), observed in the Serengeti region over more than 2 yrs during 1969–78.

Table 1 shows that single males in the Serengeti region were rarely successful in gaining tenure of a pride (4/23), whereas pairs quite often were (23/39 pairs); large groups (3 or more males) were almost always in possession of a pride (20/21 groups).

Having gained tenure, large male groups were also more successful in retaining it. Data henceforth refer to 25 male

© 1979 Macmillan Journals Ltd

groups. Figure 1*a* shows that compared with pairs (mean tenure 18 months), groups of 3 males stayed at least 2.3 times as long, and groups of six males stayed over 3.8 times as long with their prides. Note that the tenure periods of all the large groups (but of only some of the small groups) are underestimated because they extended beyond the beginning or end of the observation periods; thus the differences shown are conservative.

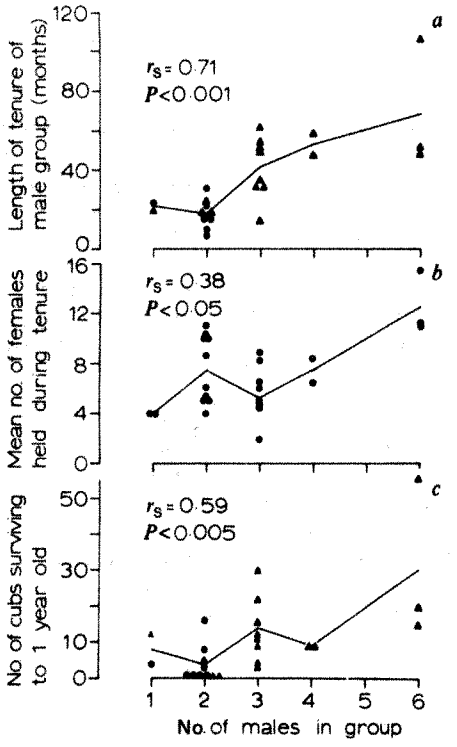

Fig. 1 Aspects of the reproductive success of male lion groups of different sizes. *a*, The numbers of months that each group retained tenure of a pride or prides in the study area. *b*, The mean numbers of females concurrently in the possession of the male groups, averaged over their observed period of tenure. *c*, The total numbers of cubs fathered during the male groups' tenure which survived to 1 yr old (by which age 77% of cub mortality has occurred[10]). ▲, Points which are minimum figures because the male groups' periods of tenure extended beyond the beginning or end of the study period; ●, points which are not underestimates.

Large male groups, especially after staying with one pride for about 2 years, may gain access to one or more neighbouring prides as well. Their concurrent tenure of several prides gives them access to more oestrous females. Figure 1*b* shows that in general only the very largest male groups (>4) held appreciably more females concurrently. They did so not by holding larger prides but by holding two or more at the same time.

When a lioness comes into oestrus (lasting 2–5 d), any male in the group consorts alone with her, mating repeatedly. Having companions should subdivide a male's share of consortships; however, the available data show no significant negative correlation between the number of males in a group and their consortship scores ($n = 50$, $r_s = +0.14$, $P > 0.2$. Consortship scores were calculated as a percentage of total sightings, excluding males sighted fewer than 10 times. For 50 males, $\bar{x} = 19.6\%$, s.d. = 8.6).

There is no detectable hierarchy within male groups[2,14], all partners sharing their mating duties with remarkable equity. For example, no male was seen consorting more than 2.7 times as often as his partner(s), and in the most often observed group of 6 males ($\bar{x} = 81$ sightings of each male) no male was involved in >22% or <9% of all consortships seen. Overall, the difference between consortship scores was smaller and far less variable between members of the same coalition ($\bar{x} = 7.6$, s.d. = 5.6, $n = 62$) than between members of different coalitions ($\bar{x} = 11.0$, s.d. = 26, $n = 1{,}138$; F test $P < 0.001$).

A female may sometimes change consorts during her oestrous period, and thus mate with more than one male. There are no indications that particular males are likely to be in consort with her at particular times during her oestrus. Copulation may occur as frequently as every 15 min, so only a minute proportion of copulations (<1%) leads to the birth of cubs[2,10]. Hence, unlike some species[15,16], for lions the number of copulations would not provide a reliable indicator even of short-term reproductive success. Nor would the number of litters born, because cub mortality is high and because high mortality of lion cubs raises the birth rate[10].

The best measure of lifetime reproductive success is the number of surviving offspring produced. Figure 1*c* shows that the total number of cubs surviving to 1 year old is correlated with their fathers' group size ($r_s = 0.59$, $P < 0.005$). The effect is achieved mainly by staying for longer and so fathering more cubs, rather than by improving their probability of survival. Nonetheless, some cub mortality is associated with male takeovers[10,14], caused by the new males killing or excluding some of their predecessors' offspring. Long tenure defers and so reduces this mortality.

We have shown above that larger groups as a whole do better. Figure 2 shows that, assuming equally shared paternity, each individual male in a large group achieves greater expected lifetime's reproductive success (that is, has greater fitness) than he would have achieved in a small group. Comparing the fitness

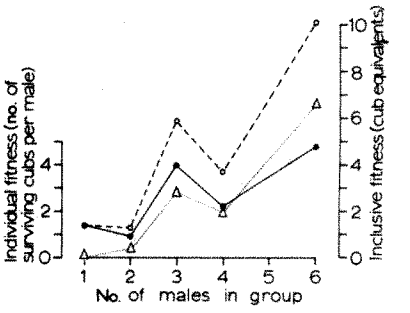

Fig. 2 Individual fitness and inclusive fitness of individual male lions in groups of different sizes. The line for mean individual fitness (●) is derived from Fig. 1*c* assuming equally shared paternity of the cubs born during the males' tenure, and multiplying by the different probabilities of achieving tenure at all (from Table 1). The line for a male's mean inclusive fitness (○) is the sum of first, the number of cubs he has fathered (that is, his mean individual fitness) and second, the number of cubs fathered by his companions multiplied by 0.22 (that is, devalued by their coefficient of relatedness to him). The lowest line (△) shows the inclusive fitness of a male who fathers no cubs of his own.

of males in large groups of 3 or more ($n_1 = 13$ groups) with that of males on their own or in pairs ($n_2 = 12$), the 3.8-fold difference is highly significant ($P = 0.001$, Mann-Whitney U-tests). The advantage does not continue to increase: thus the males in the few (5) very large groups (≥4 males) do not have higher fitness than the males in groups of 3.

The male lions in a coalition are generally relatives: it has been calculated[14] that a male's average degree of relatedness to his companions is 0.22, and that this is almost independent of group size. Cubs fathered by other males in the group also contribute to his inclusive fitness[5,17]. We ignore for present purposes the common increment to inclusive fitness produced by the reproduction of all other relatives everywhere, and consider only the contribution by other members of the male group. It can

generally be assumed that a male forms a coalition with similar-age relatives if he has them. (This was true of 19 out of 21 coalitions whose origins were known; the other two cases were a pair of strangers and a trio of two brothers and a stranger.) The inclusive fitness of each male can thus be calculated, and is illustrated in Fig. 2. There is a marked increase in the inclusive fitness of a male the more related companions he has, such that the inclusive fitness of a male in a large group is 5.7 times that of a lone male or of one of a pair. The initial individual advantage gained through cooperation is amplified through kin selection[5,14,17].

We have assumed in our calculations that paternity (like consortships) is shared equally by all members of a coalition; naturally this is not certain, nor can it be tested in wild populations. However, it can be shown that even if paternity were unequally shared, the inclusive fitness of every member of a large kin-related coalition would still exceed that of a lone male or one of a pair. In the most extreme and improbable case, although a male might sire no cubs of his own, his support of the coalition would enhance the survival of his relatives' cubs. Other things being equal, this would therefore be a better genetic strategy for him than leaving the coalition (Fig. 2).

If members of large groups generally enjoy higher reproductive success, why do not all male lions form large coalitions? It is apparently difficult to form a successful coalition, probably because the bonds necessary have to be developed early in life. Although single unrelated males can sometimes form stable pairs eventually, they seem unable to form or join larger groups, which are intolerant towards strangers. Thus the size of male groups is determined by lion prides' ability to produce and rear male offspring. The small litter size (mean 2.5 cubs[10]), overall even sex ratio[2], and high (~75%) cub mortality[2,10,12] mean that a large male peer group can reliably result only if a considerable number of lionesses in a large pride give birth synchronously. There are indications that prides in fact manage to produce large groups of young males more often than expected (J.D.B. and J.P.H., unpublished data), and how they do so is being investigated. Why they do so is now clear: females who manage to produce large groups of male cubs produce through them disproportionately many grandcubs. Previous cooperation by their mothers (in synchronising births[10] and in rearing cubs cooperatively[2,10]) is a prerequisite for the high lifetime's reproductive success of male lions cooperating in large coalitions.

Inhibition of mixed lymphocyte response by monoclonal antibody specific for a rat T lymphocyte subset

Michael Webb, Donald W. Mason & Alan F. Williams

MRC Cellular Immunology Unit, Sir William Dunn School of Pathology, University of Oxford, Oxford, UK

Cell-surface differentiation antigens which are associated with particular lymphocyte subsets are likely to be molecules which mediate specific functions of the cells which display them. One way to investigate this hypothesis is to see whether antibodies directed against such antigens will inhibit functional systems. This approach can be attempted with confidence if monoclonal antibodies are used, as these react with one antigenic determinant only and can be used in purified form. In this report we show that a monoclonal antibody which is specific for a subset of rat T lymphocytes inhibits the mixed lymphocyte response (MLR). The antibody acts on the responder cells without killing them.

The W3/25 mouse monoclonal antibody is specific for thymocytes and a subset of T lymphocytes in the rat and the cells in thoracic duct lymph that express the target antigen mediate helper and graft-versus-host functions[1,2]. The W3/25 antigen is relatively sparsely represented on the cell membrane as only about 15,000 molecules of W3/25 antibody are bound at saturation to thymocytes or T cells, yet more than 5×10^5 anti-Thy-1.1 antibodies bind per rat thymocyte[1].

The effect of W3/25 IgG on the MLR is shown in Fig. 1. In these experiments 2×10^5 lymph node cells from PVG/c ($RT1^c$) rats were used as responders to 5×10^5 irradiated spleen cells from the congeneic strain HO.B2 ($RT1^u$) in 0.2 ml cultures as described by Antczak *et al.*[3]. The W3/25 antibody was added to the cells at the start of the culture period and 0.5 μCi of tritiated thymidine (^{3}H-TdR) were added after 72, 96 or 120 h in culture. After a further 18 h the cells were assayed for incorporated label. All assays were carried out in triplicate. Concentrations of W3/25 IgG up to 2.5 ng ml^{-1} in 0.2 ml gave no inhibition but at a concentration of 25 ng ml^{-1} the antibody reduced incorporations of ^{3}H-TdR to a plateau level which was not affected by further increases in antibody concentration. We have observed this inhibition without exception in nine experiments where W3/25 antibody was added to MLRs. In 21 independent observations spread throughout these experiments the mean incorporation of fully inhibited cultures compared with control MLRs was 18.2%, standard deviation 7.3%. Within any one experiment the inhibition became greater, relative to a control MLR, with time up to 120 h. The inhibition was not confined to MLRs with PVG/c versus HO.B2 cells but was also seen in the reverse combination (see also Table 2) and in two other strain combinations which were tested (AO versus DA and PVG/c versus DA).

Other monoclonal antibodies were tested, including W3/13 antibody, which labels all T cells but not B cells[1]; MRC OX 1 antibody, which labels all leukocytes[4] and a monoclonal mouse IgG anti-Thy-1.1 antibody called MRC OX 7 (W. R. McMaster, unpublished) which labels thymocytes but only a small proportion of peripheral T cells in the rat[5]. These antibodies all bind at levels per labelled cell which are at least 2.5 times greater than W3/25 antibody, yet none inhibited the MLR, and W3/13 antibody gave a consistent stimulation of ^{3}H-TdR incorporation (data for W3/25 and W3/13 in Fig. 1; that for MRC OX 1 and MRC OX 7 not shown). For W3/25 and W3/13 antibodies, the extent of binding was checked at 37 °C and greater than 90% saturation was achieved with the same assay conditions used for the MLR at 25 ng ml^{-1} for W3/25 and 5 μg ml^{-1} for W3/13 antibody (D. W. M., unpublished). Furthermore, W3/13 antibody failed to have an inhibitory effect even at a concentration

© 1979 Macmillan Journals Ltd

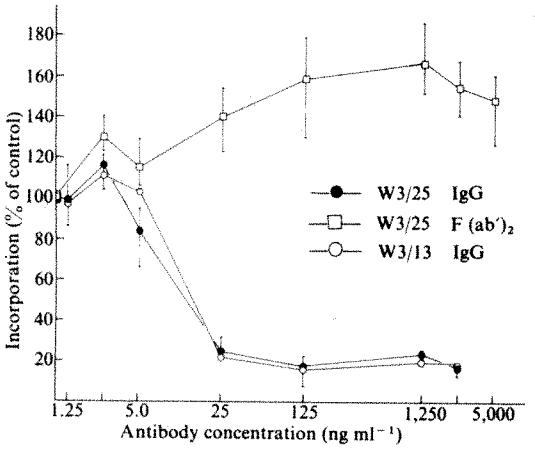

Fig. 1 Effect of W3/25 and W3/13 antibody on the MLR. Data from two independent experiments have been normalised by putting the control MLR incorporation at 100%. The control values were 22×10^3 c.p.m. for the W3/25 experiment and 40×10^3 for the W3/13 experiment. The W3/25 and W3/13 antibodies were added as pure IgG or $F(ab')_2$ prepared by standard procedures. The $F(ab')_2$ contained no IgG detectable by SDS-polyacrylamide gel electrophoresis. The W3/25 IgG contained no myeloma kappa chain since the W3/25 HL hybridoma was used[2]. W3/13 contained some myeloma kappa at a minor level compared with the antibody L chain. Ranges are shown for W3/13 IgG and W3/25 IgG. Ranges for W3/25 $F(ab')_2$ were generally similar to those for W3/25 IgG.

of 50 μg ml^{-1} (data not shown). These observations mean that it is very unlikely that W3/13 antibody did not have an inhibitory effect because it was not used at an adequate concentration.

$F(ab')_2$ fragments prepared from W3/25 IgG also inhibited the MLR and exhibited the same dose–response curve as purified IgG (Fig. 1), indicating that the Fc portion of the antibody molecule is not involved. The serological specificity of the effect was shown by the fact that the inhibition was relieved by absorption of the antibody with rat thymocytes, whereas absorption with rabbit thymocytes had no effect (Table 1).

The effect of W3/25 antibody on responses to T-cell mitogens was investigated by incubating lymph node cells with concanavalin A (Con A) and phytohaemagglutinin (PHA) in the presence of antibody. Cell proliferation caused by these agents was assayed by ^{3}H-TdR incorporation after 48 h in culture and was not significantly inhibited by W3/25 antibody at a concentration as high as 2.5 μg ml^{-1} (Table 1). This is 100 times the level required to give maximal inhibition of the MLR. The potent inhibition of cell proliferation exerted by W3/25 antibody when cells are stimulated by alloantigens does not, therefore, extend to the proliferation induced by T-cell mitogens.

Table 1 Effect of various treatments on the MLR of PVG/c lymph node cells responding to irradiated HO.B_2 spleen cells

Treatment		^{3}H-TdR incorporation (c.p.m. × 10^{-3} per 18-h pulse)
Rat absorption		
Control MLR (2×10^5 cells)		54
+unabsorbed W3/25 antibody		11
+W3/25 absorbed with 6×10^7 rat thymocytes		72
Rabbit absorption		
Control MLR (2×10^5 cells)		52
+unabsorbed W3/25 antibody		11
+W3/25 absorbed with 5×10^7 rabbit thymocytes		9
PHA stimulation		
Control (3.5×10^4 cells)		35
+25 ng per ml W3/25 IgG		37
+2,500 ng per ml W3/25 IgG		32
Con A stimulation		
Control (3.5×10^4 cells)		32
+25 ng per ml W3/25 IgG		58
+2,500 ng per ml W3/25 IgG		31
Control MLR with no preincubation	0 h	38
2×10^5 cells cultured for various times	4 h	61
without addition of antibody before MLR	8 h	73
	24 h	37
	48 h	15
2×10^5 cells cultured for various times	4 h	40
with W3/25 IgG (25 ng ml^{-1}) before MLR	8 h	24
	24 h	63
	48 h	12

In the absorption experiments W3/25 antibody was used in the form of spent tissue culture medium from cultures of cells secreting W3/25 antibody (0.4 μl per culture) while in the other experiments pure W3/25 HL IgG was used. Con A was used at a final concentration of 10 μg ml^{-1} and PHA at 20 μg ml^{-1}.

To discount the possibility that the responding cells in the MLR are killed by the antibody, lymph node cells were cultured without stimulator cells at 37 °C in the presence or absence of W3/25 antibody (25 ng ml^{-1}). They were then washed twice and resuspended in medium lacking antibody and assayed in a standard MLR. These experiments showed that cells could be incubated in the presence of antibody without any reproducible indication that this affected their ability to respond to

Table 2 Alloreactivity of W3/25$^+$ and W3/25$^-$ lymphoid populations

	Incubation period	Responders	Stimulators	^{3}H-TdR incorporation (c.p.m. × 10^{-3} per 18-h pulse)		
				Unstimulated control	MLR	MLR + W3/25 IgG (25 ng ml^{-1})
Expt 1	72 h	2×10^5 W3/25$^+$ (PVG/c)	5×10^5 HO.B2 spleen cells	0.1	57	—
	72 h	2×10^5 W3/25$^-$ (PVG/c)	5×10^5 HO.B2 spleen cells	0.1	7	—
Expt 2	72 h	2×10^5 W3/25$^+$ (PVG/c)	5×10^5 HO.B2 spleen cells	1	17	—
	72 h	2×10^5 W3/25$^-$ (PVG/c)	5×10^5 HO.B2 spleen cells	0.2	4	—
Expt 3	96 h	2×10^5 HO.B2 lymph node cells (unfractionated)	5×10^5 irradiated W3/25$^-$ PVG/c thoracic duct lymphocytes	2	18	3

Each value is the mean of triplicate assays where the range was always < ±15% of the mean. In experiments 1 and 2 MLR's were also done with responders at 1×10^5 and 5×10^5 cells per culture. Typical dose–response curves were obtained and the ratio of W3/25$^+$: W3/25$^-$ responses was similar to that obtained with 2×10^5 responders.

subsequent alloantigenic stimulation. The results of one such experiment are shown in Table 1 with preincubations for various times. At only one time point (8 h) did there appear to be any effect on the subsequent MLR. In another experiment (data not shown) where cells were preincubated for 24 or 48 h no inhibition was observed.

These findings show that W3/25 antibody inhibits the MLR quite specifically without killing the cells. This effect prompts questions about the role of W3/25 positive cells in the MLR. It might be expected that the major part of the cell proliferation in the MLR is due to W3/25 positive cells and that in conditions of inhibition by W3/25 antibody these cells have no role as responders. This possibility was investigated using a fluorescence activated cell sorter to prepare populations of W3/25-positive and -negative cells from thoracic duct lymph[2]. In two independent experiments, covering a range of responding cell doses, and culture periods of 72 and 96 h, the incorporation of ^{3}H-TdR by W3/25-positive cells was found to be at least four times that of the W3/25-negative cells when equal numbers of responding cells were compared (Table 2).

In a third experiment, stimulator cells were depleted of W3/25-positive T cells in the cell sorter to a level of 0.8% contamination and used to stimulate fresh lymph node cells. The W3/25-negative cells acted efficiently as stimulators (Table 2) and the resultant MLR could be inhibited by W3/25 antibody giving the same dose–response curve as that shown in Fig. 1 (incorporation by culture treated with 25 ng ml^{-1} W3/25 IgG = 19.3% of control MLR). Similar results were obtained in another experiment. It might be argued that the stimulator effect in these experiments was dependent on very small numbers of W3/25-positive contaminating cells. However, this is unlikely as although W3/25-positive cells were able to stimulate an MLR, they were no more potent than W3/25-negative cells and when added at 2×10^4 cells per culture gave no detectable stimulation of the MLR (M. W., unpublished). This number of W3/25-positive cells is five times greater than the estimated number of contaminating cells present in the W3/25-negative stimulators used in experiment 3 of Table 2.

These results suggest that the targets of the antibody are the responding cells rather than the stimulating cells, and the inhibition data indicate a blocking function for added W3/25 antibody. It is thus possible that the W3/25 molecule is of functional significance in the MLR response.

Lymphocytotoxic antibodies produced by H–2 allo-immunisation distinguish between MuLV-positive and -negative substrains of the same H-2 haplotype

Pavol Ivanyi, Cornelis J. M. Melief, Peter van Mourik, Arjen Vlug & Paul de Greeve

Central Laboratory of the Netherlands Red Cross Blood Transfusion Service and Laboratory for Experimental and Clinical Immunology, University of Amsterdam, Amsterdam, The Netherlands

In C57BL mice of certain H–2 types, such as B10.A (H–2^a), ecotropic leukemia virus has been shown to be transmitted by milk-borne infection. By selecting virus-positive and virus-negative B10.A mothers and foster-nursing the B10 (H–2^b) newborn animals, four sub-lines of C57BL/10 mice have been obtained—B10.A V$^+$, B10.A V$^-$, B10 V$^+$ and B10 V$^-$ (see Fig. 1 and ref. 1). Milk transmission of naturally prevalent B-tropic virus (V$^+$ sub-lines) leads to a persistent infection of all the offspring over more than 8 generations[2]. We have studied the consequences of this kind of virus infection on the expression and immunogenicity of antigens coded for by the H–2 complex. This complex exerts a marked influence on oncogenesis by a variety of oncogenic RNA viruses[3,4]. The H–2K and H–2D loci restrict the specificity of virus-specific cytotoxic T lymphocytes[5]. In some instances, a direct physical association between H–2 and viral antigens has been demonstrated[6–10]. In our work, groups of B10.A V$^+$ and B10.A V$^-$ mice were immunised with B10 V$^+$ and B10 V$^-$ lymphoid cells. Production of anti-H–2^b antibodies was expected and observed in these sera. However, surprisingly, in the combination of B10 V$^+$ donor and B10.A V$^-$ recipient, after prolonged hyperimmunisation, we obtained sera that reacted positively in the routine microlymphocytotoxicity test with B10.A V$^+$ lymph-node cells, but not with B10.A V$^-$ cells. B10 V$^-$ cells were able to absorb this antibody. Our preliminary conclusion is that the milk-transmitted virus, soon after birth, introduces a serologically detectable antigen which is recognised in association with H–2. The prerequisite for the formation of this kind of antibody is the immunisation of H–2 haplotype-different V$^-$ recipients with V$^+$ donor cells.

The derivation of sub-lines of C57BL/10 (B10) mice with (V$^+$) and without (V$^-$) milk-transmitted B-tropic virus is schematically presented in Fig. 1. The individual mice used in the experiments were from the 10th to 12th generation of the respective lines after their original preparation. For immunisations, donor spleen + thymus + lymph-node cells (in 'doses' of 1 donor per 10 recipients) were injected intraperitoneally at weekly intervals with a 1-week interval after every fourth injection. Serum samples were collected every week, 3–4 days after injection or 3–9 days after the last immunisation[11]. The routine microlymphocytotoxicity test on mouse lymph-node cells (or spleen cells) was carried out in serial geometrical dilutions[11]. Immunofluorescence tests were carried out using a fluorescein-labelled rabbit anti-mouse IgG serum, prepared in our Institute. Antibodies against AKR type viral-envelope antigens (VEA) were measured by a radioimmunoprecipitation (RIP) test[2].

The results of four immunisations, carried out in the combination of donor B10, recipient B10.A, are listed in Table 1. All sera exhibited an almost equally strong cytotoxic reaction on cells of the B10 V$^+$ and B10 V$^-$ substrains. An unexpectedly strong cytotoxic reaction was observed with serum CLS-12 (B10 V$^+$ donor, B10.A V$^-$ recipient) with the lymph-node (or spleen) cells of B10.A V$^+$ mice. More than 20 randomly chosen individual mice of the B10.A V$^+$ and B10.A V$^-$ substrains, of both sexes, 1–10 months old, were tested. The result was always the same; the individuals V$^+$ reacted positively whereas the

* Strain designation and H-2 alleles at the K and D locus.
† Letters B to Q designate the serial serum sample; the number in parentheses shows the week of immunisation.
‡ Sera were only tested in six dilutions. All reactions with strains B10 V$^+$, B10 V$^-$, B10.A (2R) and B10.A (5R) were still strongly positive at dilution 1:64.

reaction with V$^-$ individuals was negative. Hence, with the routine microlymphocytotoxicity test, simple 'serotyping' of the B10.A V$^+$–B10.A V$^-$ difference became possible.

The anti-V$^+$ activity in the CLS-12 combination developed after about 12 weeks of allo-immunisation. None of the CLS-10, CLS-11 or CLS-13 sera, prepared and tested in parallel, exhibited this kind of activity (Table 1). The data in Table 1 were obtained by testing serum pools obtained from four to six mice from the immunised groups. Because we have shown previously[11,12] that individual mice of one inbred strain differ widely in their ability to produce anti-H-2 antibodies, the serum samples taken during the last two weeks of immunisation (R+S weeks) were tested as samples of individual mice, not as serum pools. The reactions of the individual CLS-12 sera (10 mice) are shown in Table 2. Of 10 sera, 7 react strongly with B10.A V$^+$ cells, but not at all with B10.A V$^-$ cells. Two sera exhibited a titre of 1:1,024 with B10.A V$^+$ cells.

Absorption experiments (Table 3) have shown that both B10 V$^+$ and B10 V$^-$ cells absorbed all cytotoxic activity from CLS-12 sera, and that with B10.A V$^+$ and control B10.A V$^-$ cells, V$^+$ cells completely removed activity only against themselves, but left strong activity against the haplotype-specific H-2^b antigens of the donor strain. B10.A V$^-$ cells absorbed neither anti-H-2^b nor anti-B10.A V$^+$ activity. The observation that B10 V$^-$ cells absorbed the anti-B10.A V$^+$ activity, whereas B10.A V$^-$ cells did not, indicates that MuLV antibodies are not responsible for the reactivity of the CLS-12 sera with B10.A V$^+$ cells. First, B10 V$^-$ cells are virus negative. Second, B10.A V$^-$ cells are virologically identical to B10 V$^-$ cells (virus negative) but they do not absorb the activity against B10.A V$^+$ lymphocytes. Two other sets of data support the conclusion that anti-MuLV antibodies are not responsible for the anti-B10.A V$^+$ activity. Two CLS-12 sera positive with B10.A V$^+$ mice were tested in the RIP assay, by far the most sensitive assay for detecting antiviral envelope antibodies, but no such antibodies were found. Moreover, we tested several mouse sera with high titres of antibodies to viral envelope antigens but none of them lysed B10.A V$^+$ lymph-node cells. Two of these sera were from 3-month-old B10.A V$^+$ mice with high levels of anti-VEA antibodies. Finally, 20 B10.A V$^-$ mice were immunised with B10.A V$^+$ cells (by an immunisation schedule identical to that applied for the preparation of the CLS-12 sera), but none of these sera became cytotoxic for B10.A V$^+$ (B10 V$^+$) lymph-node cells. The tests were carried out after 8, 9, 18 and 20 weeks of immunisation; in comparison (Table 1), CLS-12 sera became positive after 12 weeks of immunisation. This finding shows that only allogeneic V$^+$ cells are able to induce cytotoxic anti-B10.A V$^+$ antibodies in B10.A V$^-$ recipients.

The results described above show a clear-cut difference between the B10.A V$^+$ and B10.A V$^-$ substrains detected by the lymphocytotoxicity test on normal cells from lymph-node or spleen. These two strains differ only in the presence of a milk-transmitted MuLV, the trait for which they were selected 10–12 generations previously. The serologically defined differences between the two strains might be based on either of two mechanisms. First, a gain mutation might have become fixed in the V$^+$ strain and have caused the appearance of a new specificity common to H-2^b and the new H-2 haplotype of B10.A V$^+$. Alternatively, a loss mutation in the B10.A V$^-$ strain would allow the production of antibodies against a common antigen shared by the H-2^b and H-2^a haplotypes. Both possibilities seem unlikely for two reasons: (1) the anti-B10.A V$^+$ antibodies occurred only in the combination defined as CLS-12 (Table 1), and (2) skin grafts survived between the B10.A V$^+$ and B10.A V$^-$ substrains (data not shown). The second possibility is that the two substrains still differ only in the original trait for which they were selected[1], that is, positive or negative for the milk-transmitted ecotropic MuLV. If this were so, embryos and newborn animals of the B10.A V$^+$ substrain should not react with CLS-12 sera, and the reactivity should develop only after drinking mother's milk.

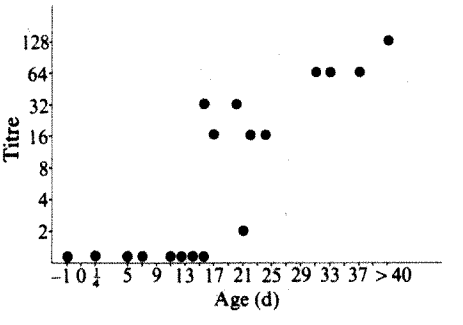

Fig. 2 Postnatal development of positivity with CLS-12 serum (no. 10, R+S bleeding) on spleen cells of B10.A V$^+$ mice. The mothers of all litters examined reacted positively (titre 1:64–128). On 1 day before and after birth, the immunofluorescence test was used; on further days, the microcytotoxicity test on spleen cells was used. Titres represent the highest serum dilution with more than 80% killed cells.

The second possiblity was examined by testing spleen cells of B10.A V$^+$ embryos and newborn mice with CLS-12 serum using immunofluorescence and cytotoxicity tests. Embryos, 1 day before birth, and newborn mice that were maintained 6 ± 3 h after birth without mother's milk, did not react with CLS-12 sera. The cytotoxicity test with CLS-12 sera became positive on spleen cells after day 45 (Fig. 2).

The antibodies in B10.A V$^-$ (H-2^a) anti-H-2^b sera which recognise the difference between B10.A V$^+$ and B10.A V$^-$ sublines of H-2^a mice, have the following characteristics: (1) anti-B10.A V$^+$ activity only occurred after immunisation of B10.A V$^-$ recipients with B10 V$^+$ cells. Such antibodies were not detectable after immunisation with B10 V$^-$ cells or after immunisation of B10.A V$^+$ recipients. (2) The anti-B10.A V$^+$ activity appeared only very late—after more than 10 weeks of allo-immunisation. (3) B10 V$^+$ and B10 V$^-$ cells each absorbed all activity. (4) B10.A V$^+$ cells absorbed only that part of the activity which was directed against the B10.A V$^+$ cells, whereas the anti-B10 V$^+$ and anti-B10 V$^-$ activity remained virtually unchanged. (5) B10.A V$^-$ cells absorbed neither the anti-H-2^b nor the anti-B10.A V$^+$ activity. (6) The target structure on the B10.A V$^+$ cells, responsible for the reaction with CLS-12 sera, developed postnatally, probably as a consequence of virus transmission through milk or placental infection. This target structure develops much later than do H-2 antigens, which are already detectable at birth by cytotoxicity and reach adult sensitivity within 1-3 days[13].

These characteristics cannot be explained by assuming that the anti-V$^+$ and anti-H-2^b activities in CLS-12 sera are due to completely separate populations of antibodies. In that case, B10 V$^-$ cells would not be expected to absorb the anti-B10.A V$^+$ activity, unless one assumes that B10 V$^-$ mice also have the V$^+$ antigen but in a form that only absorbs and is not immunogeneic. This possiblity seems far fetched. Indeed, B10 V$^-$ mice express little or no viral structural proteins despite the presence in their genome of latent DNA pro-viruses[1,2,14,15]. Moreover, B10.A V$^-$ cells, that do not differ from B10 V$^-$ cells in the lack of expression of infectious virus and/or viral structural proteins[1,2], do not absorb the activity against B10.A V$^+$. Therefore, it seems likely that all cytotoxic activity of CLS-12 sera is due to anti-H-2^b antibodies, including the anti-B10.A V$^+$ activity. On the other hand, the antibody activity against B10.A V$^+$ cells constitutes only minor fraction of the anti-H-2^b sera, because after absorption with B10.A V$^+$ cells, all activity against B10.A V$^+$ is removed, whereas strong anti-H-2^b activity remains.

Having considered all these points, we propose the following explanation for the current observation. Milk-transmitted MuLV induces a lymphocyte antigen (V$^+$) which in association with allogeneic H-2^b structures becomes immunogenic in the late phase of B10.A V$^-$/anti-B10 V$^+$ immunisation. The resulting antiserum cross-reacts with an antigen on normal B10.A V$^+$ lymph-node cells (and spleen cells) in the microlymphocytotoxicity test. The target antigen on B10.A V$^+$ lymphocytes develops within a few days after birth. Whether physical association between V$^+$ and H-2 structures is necessary for immunogenicity remains unclear. The observation that antibody against this antigen was only produced after allo-immunisation in the combination of B10 V$^+$ donor, B10.A V$^-$ recipient, as well as the finding that B10 V$^-$ absorbed all antibody activity, suggests that the immunogen is intimately related to H-2 and possibly represents a virus-altered H-2 antigen.

These investigations were supported in part by the FUNGO, which is subsidised by the Netherlands Organization for the Advancement of Pure Research (ZWO) and the Foundation Queen Wilhelmina Fund/Netherlands Organization against Cancer.

Table 2 Reaction pattern of 10 individual anti-H-2^b (CLS-12) sera

Individual recipients mouse no.	Microlymphocytotoxicity titre on cells* B10A V$^+$	B10.A V$^-$
1	8	0
2	16	0
3	64	0
4	0	0
5	64	0
6	4	0
7	1,024	0
8	1,024	0
9	2	0
10	64	0

The serum samples from individual mice were pools obtained from bleedings on the R(18th) and S(19th) weeks of immunisation.
* All sera had a titre > 1 : 1,024 on B10 V$^+$ and B10 V$^-$ cells.

Table 3 Absorption experiments with CLS-12 (B10 V$^+$ donor, B10.A V$^-$ recipient) sera

Serum designation	Cells used for absorption	Dose	Cells tested after absorption B10 V$^+$	B10 V$^-$	B10.A V$^+$	B10.A V$^-$
CLS-12-S-8	None		1,024	1,024	1,024	0
	B10 V$^+$	100×10^6	0	0	0	0
	B10 V$^-$	100×10^6	0	0	0	0
CLS-12-R-7	B10.A V$^+$	100×10^6	1,024	0	0	0
	B10.A V$^-$	100×10^6	1,024	1,024	1,024	0

Identical results were obtained with two other CLS-12 sera. 50 μl of serum CLS-12 were absorbed with spleen + lymph-node cells.

Diethylcarbamazine enhances antibody-mediated cellular adherence to *Brugia malayi* microfilariae

Willy F. Piessens & Maria Beldekas

Harvard Medical School, Peter B. and Robert B. Brigham Hospitals, Boston, Massachusetts 02115

Treatment with the antifilarial drug diethylcarbamazine (DEC) results in a rapid decline in the number of microfilariae circulating in the blood of infected hosts[1]. DEC induces morphological changes in the surface layers of microfilariae, but these alterations alone are probably insufficient to cause the death of the parasite, because the drug fails to reduce microfilaraemia in animals lacking filarial antibodies, and also does not shorten the survival of microfilariae *in vitro*[1-4]. The effect of DEC *in vivo* is thought to result from the trapping of microfilariae in the liver, where they undergo lysis[1,2,5,6].

Peripheral blood leukocytes from uninfected donors can be made to adhere to microfilariae of *Brugia malayi in vitro*; cellular adherence is promoted by antibodies reacting with the microfilarial sheath, or by a heat labile factor present in normal serum (thought to be complement). The adherence promoting antibody is probably of the IgG class because: (1) only patients' sera that contain high titres of IgG antisheath antibodies

detected by indirect immunofluorescence are active in this regard; (2) the adherence reaction is reversed by the addition of low concentrations of staphylococcal protein A which binds to the Fc portion of IgG (unpublished observation); and (3) purified IgG antisheath antibody promotes similar adherence of cells to microfilariae of *Wuchereria bancrofti*[7]. To investigate further the mechanism of action of DEC, we examined the effect of this drug on the adherence reaction. The results indicate that DEC enhances antibody-, but not complement-mediated adherence of buffy coat cells from normal donors to *B. malayi* microfilariae. The effect results from a direct action of the drug on microfilariae and not from a functional activation of leukocytes.

The adherence assay was carried out by sequentially adding the following constituents, each in 0.05 ml volumes to triplicate wells of round-bottom microtitre plates: microfilariae ($4{,}000\ ml^{-1}$); diluted antiserum (see below), fresh human serum diluted 1:4 and/or culture medium (Hanks' minimal essential medium, MEM); and buffy coat cells (2×10^5, prepared by dextran sedimentation of blood from normal volunteers). Serum from three different subjects with elephantiasis due to *B. malayi* was used as the source of IgG microfilarial antibody; these sera were diluted with MEM to promote cellular adherence in the absence of DEC to less than 35% test microfilariae. DEC was dissolved in MEM; the *p*H of the solution was adjusted to 7.4 with bicarbonate buffer. Adherence was scored after 2 h of incubation at 37 °C.

DEC increased the proportion of microfilariae that formed rosettes with buffy coat leukocytes in the presence of antisheath antibodies in a dose-dependent fashion. The results of five representative experiments in which a wide range of drug concentrations was tested simultaneously are shown in Table 1.

The number of adhering cells per worm was also increased in the presence of DEC, but this phenomenon was difficult to quantitate. In the absence of DEC, 5–20 cells were attached to the surface of microfilariae; in the presence of the drug, most worms were surrounded by several concentric layers of cells, generally exceeding 50 in number. No adverse effects on the motility or viability of microfilariae were observed during the short (2 h) culture period. Microfilariae of *W. bancrofti* are killed under similar experimental conditions, but only after longer periods of incubation[7].

In preparations stained with Wright–Giemsa, lymphocytes, neutrophils, eosinophils and monocytes were seen to adhere to microfilariae; DEC did not selectively increase the adherence of one or another cell type to the worms.

To determine whether the increased cellular adherence resulted from an effect of the drug on the microfilariae, on the leukocytes or on both, experiments were done in which microfilariae or buffy coat cells were incubated separately with DEC and then washed extensively before they were used in the adherence assay. Preincubation of leukocytes with the drug did not increase cellular adherence to microfilariae. In contrast, preincubation of microfilariae markedly enhanced the proportion of worm-cell rosettes formed in the presence of antibody (Table 2). In seven experiments, complement-mediated adherence of buffy coat cells to microfilariae was not enhanced by DEC added in final concentrations of up to 250 $\mu g\ ml^{-1}$. Similarly, DEC did not increase the proportion of worms forming rosettes with cells in serum-free medium.

These results clearly indicate that diethylcarbamazine increases the adherence of leukocytes to *B. malayi* microfilariae mediated by antibodies reacting with the surface of the worms. The effect appears to result from a direct action of the drug on microfilariae. However, drug-induced surface alterations *per se* do not promote cellular adherence *in vitro* in the absence of microfilarial antibodies. Likewise, such changes do not promote the *in vivo* hepatic trapping of microfilariae in experimental animals unless antibodies are also present in the treated host[4]. Treatment with DEC of human subjects with patent microfilaraemia rapidly reduces the number of circulating microfilariae. Yet, the serum of such patients contains no antisheath antibodies detectable by indirect immunofluorescence. There are several possible explanations for this apparent discrepancy: it is possible that antisheath antibody titres in microfilaraemia are too low to be detected by rather insensitive immunofluorescent methods; such antibodies may already be bound to the parasites and therefore not readily detectable in serum; or DEC may act *in vivo* by several mechanisms of which only one is measured by the *in vitro* assay used for these studies. In addition, our findings are also consistent with the hypothesis that DEC may act by rendering accessible previously hidden antigenic determinants, antibodies to which might not be detectable in immunofluorescent assays using non drug-treated microfilariae. The observation that some sera from *B. malayi* infected donors fail to promote cellular adherence to microfilariae in the absence of DEC, but enhance adherence in the presence of the drug (Table 3) supports this hypothesis. The mechanism by which DEC unmasks parasite antigens and the exact nature of these antigenic determinants remain to be determined.

We thank Dr J. B. Johnson of Lederle Laboratories for supplying diethylcarbamazine (Hetrazan). These studies were supported by a grant from the Rockefeller Foundation.

Table 2 Enhanced antibody-mediated cellular adherence following pretreatment of microfilariae with DEC

DEC concentration ($\mu g\ ml^{-1}$)	% Microfilariae with ≥5 cells attached	
	Worms pretreated	Cells pretreated
0	27±3	27±3

Genomic rearrangements correlated with antigenic variation in *Trypanosoma brucei*

Richard O. Williams, John R. Young & Phelix A. O. Majiwa

International Laboratory for Research on Animal Diseases (ILRAD), PO Box 30709, Nairobi, Kenya

The capacity of African trypanosomes to express sequentially a large repertoire of different surface antigens during an infection[1–3] enables the parasite to evade the immune response of its host, and makes attempts to produce a vaccine against the disease difficult. It is evident that point mutations cannot account for antigen diversity[4,5]. Variable antigens like immunoglobulins are derived from an extensive family of genes of which only one is expressed in a given cell. As somatic recombination is involved in the immunoglobulin gene system[6], this similarity prompted us to search for somatic rearrangements in trypanosome variable antigen genes. We have constructed a recombinant plasmid containing approximately half the DNA sequence coding for a *Trypanosoma brucei* variable antigen and hybridised the inserted sequences to various restriction enzyme digests of nuclear DNA from different trypanosome clones. Differences in the sizes of restriction fragments hybridising to the inserted variable antigen coding sequence show altered positions of enzyme sites relative to this sequence, indicating different arrangements of DNA sequences around this gene in different trypanosome clones.

Three clones of *T. brucei* expressing different variable antigens were derived from stock LUMP 227 (UHEMBO/64/EATRO/795). Clone A was derived from a relapse infection of clone C. Clone B was derived from a relapse infection of clone A. Clone X was derived from a different trypanosome stock, S427. All trypanosome populations, grown in lethally irradiated rats for these studies, were monitored for variable antigen type homogeneity by immunofluorescent techniques[7].

Messenger RNA was prepared from *T. brucei* clone A, expressing variable antigen ILTat 1.2, as described previously[8]. A preparation enriched for variable antigen mRNA was obtained by two cycles of density gradient centrifugation. Double-stranded cDNA was made on this template by a slight modification of the procedure of Wickens *et al.*[9], and inserted into the plasmid vector pBR322 by the G–C boundary method[10]. Transformed bacteria containing recombinant plasmids were screened by *in situ* filter hybridisation[11]. Isolated plasmids were further screened for variable antigen coding sequences by hybrid-arrested translation[12]. Thus it was shown that plasmid pcB602 contains variable antigen coding sequences (Figs 1 and 2).

A filter hybridisation of the inserted sequences of pcB602 to *Hin*dIII fragments of nuclear DNA from four different *T. brucei* clones is shown in Fig. 3. In all clones there is a strongly hybridising fragment. It is the same size in clones B and C (4.5 kilobases) but slightly larger (5.0 kilobases) in clone A, this clone expressing the sequences in the probe. In clones B and C

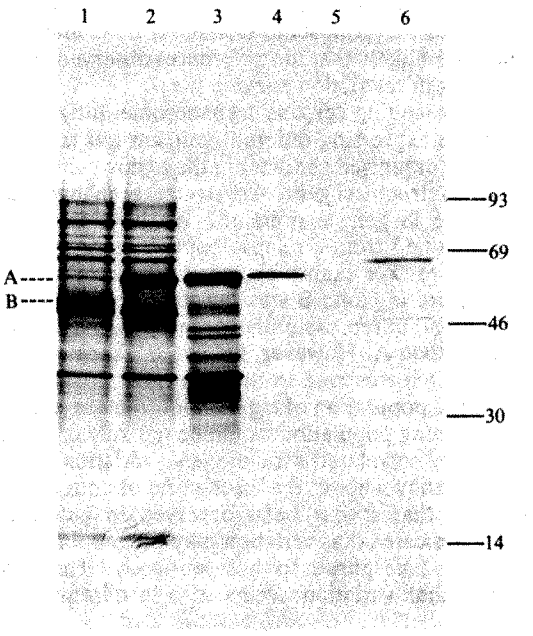

Fig. 1 Identification of variable antigen band in SDS polyacrylamide gel electrophoresis of *in vitro* translation products. Translation products of total mRNA from *T. brucei* clones: lane 1, clone B; lane 2, clone A; lane 3, translation products of partially enriched variable antigen mRNA from clone A. Translation products of total mRNA from clone A immunoprecipitated with: lane 4, antiserum against clone A antigen; lane 5, with normal rabbit serum. Lane 6, immunoprecipitate of variable antigen from *in vivo* labelled trypanosome with anti-clone A variable antigen antiserum. Antiserum was raised against purified variable antigen[20] by conventional procedures. Polyadenylated RNA was further purified by two cycles of sucrose density gradient centrifugation. Translation products were made in the rabbit reticulocyte cell-free system[21]. Solubilised extracts of ^{35}S-methionine-labelled proteins from the cell free translation reactions and from trypanosomes labelled *in vivo* (S. Z. Shapiro, unpublished) were made by the procedure of Shapiro and August[22] and immunoprecipitated by the proceure of Kessler[23]. Electrophoresis was performed with a 7.5–17.5% polyacrylamide gradient slab gel containing 0.1% SDS using the discontinuous buffer system of Maizel[24]. Position of *in vitro* synthesised variable antigen bands are indicated at A (clone A) and at B (clone B). The former is identified by immunoprecipitation. It has a lower apparent molecular weight (60,000) than the glycosylated *in vivo* labelled protein (63,000) as expected[8].

there is a less strongly hybridising fragment of very different size in each clone, 7 kilobases in clone B and 8.5 kilobases in clone C. In clone A there is weaker hybridisation to three fragments, 11, 8 and 6 kilobases long.

Plasmid pcB602 has been sequenced (K. Chen, J. E. Donelson and R.O.W., unpublished work). It contains 902 base pairs of coding sequence. There is a single *Hin*dIII site which is 293 base pairs from one end. If the same site were present in genomic DNA we would expect to find at least two genomic *Hin*dIII fragments hybridising to the two segments of the probe sequence. This would be consistent with what is seen with clones B and C. With clone A there are three weakly hybridising fragments. This could result from the presence of *Hin*dIII sites in very long intervening sequences, or asymmetric length heterogeneity of multiple gene copies. There is no evidence concerning gene reiteration.

Using nuclear DNA from clone X, some hybridisation to a fragment of very different size from the major fragments observed in the other clones (13 kilobases) was detected. This result shows that this clone contains a genomic sequence of sufficient homology to the clone A antigen coding sequence to hybridise in these conditions. In similar experiments using genomic DNAs digested with the restriction enzymes *Hin*cII,

0028–0836/79/510847—03$01.00

© 1979 Macmillan Journals Ltd

*Hin*fI and *Xho*I differences in hybridisation patterns were observed between trypanosome clones A, B, C and X in all cases. Thus it is unlikely that the differences observed are due to point mutations in restriction enzyme sites.

The sequence coding for one trypanosome antigen is conserved in clones expressing different antigens but these clones have differently organised genomes in the region containing the clone A antigen structural gene. Are structural changes responsible for change in gene expression? We have found that a trypanosome cloned from a relapse population has an altered genomic structure. We cannot exclude the possibility that the genomic structure in clone B was selected fortuitously by the cloning of a single unrepresentative organism from the relapse population of clone A. However, neither weaker nor stronger bands in clone B correspond to those in clone A. The cloning from the relapse population of a genomic structure not detectable in the infecting population would be unlikely unless structural changes are correlated with antigenic variation.

Very little is known about the mechanism of antigenic variation. The fact that it has been observed in cultured trypanosomes[13] indicates that variation may occur spontaneously rather than as a response to host antibody. The simplest assumption is that variation occurs at a low frequency in a trypanosome population, and that new variants become apparent in successive waves of parasitaemia as the preceding ones are eliminated by the host's immune system[3]. If this is an accurate interpretation, then we are observing an alteration of gene expression which is stably inherited by the vast majority of progeny cells. The process resembles differentiation in higher eukaryotes more than transient forms of control of gene expression, such as hormonal regulation. Thus antigenic variation may provide an important model for some general processes in eukaryotic differentiation.

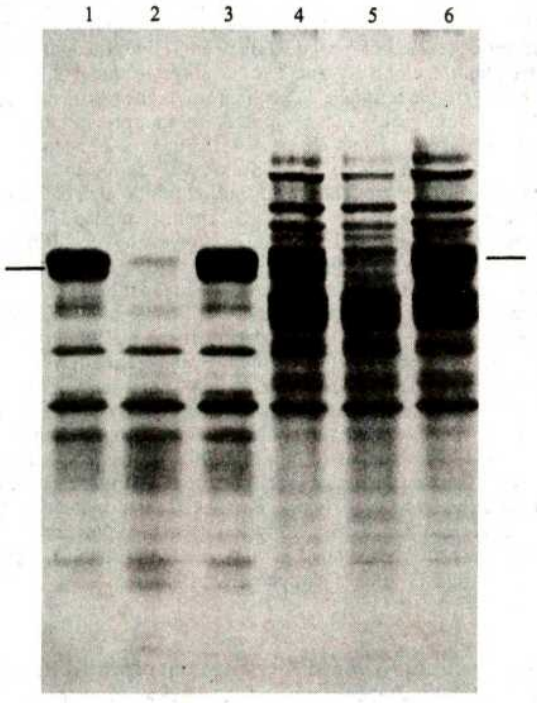

Fig. 2 Hybrid-arrested translation confirming that pcB602 contains variable antigen coding sequences. Translation products of partially enriched variable antigen mRNA; lane 1, unhybridised; lane 2, hybridised with pcB602; lane 3, hybridised with pcB602 then denatured by boiling. Translation products of total mRNA: lane 4, unhybridised; lane 5, hybridised with pcB602; lane 6, hybridised with pcB602 then denatured by boiling. Hybridisations, carried out according to Paterson[12], contained in a final volume of 50 μl, 10 μg of *Hae*III-digested pcB602 and 1 μg of enriched mRNA fraction or 2 μg *Hae*III-digested pcB602 and 1 μg total mRNA. After 4 h at 48 °C, 100 μl of cold water was added and the mixture was divided. One aliquot was boiled for 90 s, before both were ethanol precipitated and translated in the rabbit reticulocyte system. Electrophoresis of translation products was through a 10% polyacrylamide SDS slab gel. The variable antigen band as identified by immunoprecipitation is marked by the horizontal bars. Specific and reversible inhibition of synthesis of this polypeptide by hybridisation with pcB602 shows that the plasmid contains variable antigen coding sequences. Control experiments with pBR322 and another recombinant plasmid containing G–C boundaries gave no inhibition of synthesis of this band.

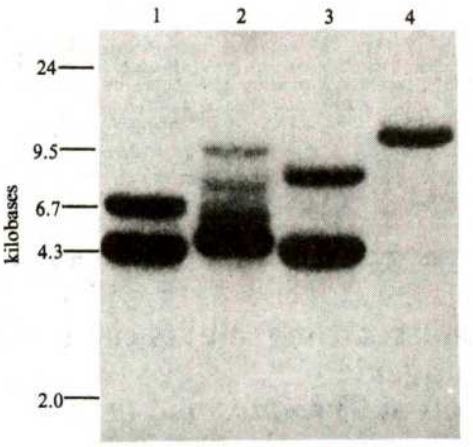

Fig. 3 Hybridisation of inserted sequences of pcB602 to *Hin*dIII fragments of nuclear DNA: lane 1, clone C; lane 2, clone A; lane 3, clone B; lane 4, clone X. Plasmid pcB602 was digested with *Pst*I. The three fragments of the inserted sequence were separated by electrophoresis, recovered from an agarose gel[25] and labelled with ^{32}P by nick translation[26] to high specific activity ($\geq 250 \times 10^6$ ^{32}P c.p.m. μg^{-1}). Nuclear DNAs were prepared from cloned trypanosomes using a modification of published procedures[27]. DNA was completely digested with the restriction enzyme *Hin*dIII and electrophoresed in 0.6% agarose gels. Fragments were transferred to nitrocellulose filters by the blotting procedure of Southern[28], and hybridised to the nick translated probe (in 120 mH Tris HCl, *p*H 7.4, 4 mM EDTA, 0.6 M NaCl, 0.1% sodium pyrophosphate, 0.1% SDS, 0.2% each of Ficoll 400, polyvinyl pyrollidone and bovine serum albumin, and 100 μg ml^{-1} sonicated denatured calf thymus DNA) at 68 °C for 60 h. After extensive washing the filters were autoradiographed using Kodak XR5 film with intensifying screens.

Our data do not allow us to distinguish between the many possible forms of DNA rearrangement that could account for the changes observed. Immunoglobulin genes are known to be constructed by movement of variable region genes into proximity with the constant region gene[6]. While trypanosome variable antigens do exhibit general immunological cross-reactivity[14], it has not yet been determined whether this involves regions of polypeptide homology or the attached carbohydrate structures (A. F. Barbet, personal communication). Therefore, we cannot implicate an analogous mechanism in construction of variable antigen genes. In prokaryotes translocatable genomic elements are known to exert control over gene expression[15–17]. Somewhat analogous translocating element hypotheses have been used for eukaryotes to explain some phenomena in the genetics of maize[18] and *Drosophila*[19]. Similar mechanisms might possibly occur in trypanosomes.

We have observed differences in genomic structure in the region containing sequences coding for the clone A variable antigen in different clones of *T. brucei* expressing this and two other antigens. We propose that the rearrangements observed may be involved in controlling the expression of this gene. A sequence with some homology to that coding for clone A variable antigen is also present in a clone from *T. brucei* stock S427.

We thank Dr J. J. Doyle for providing trypanosome clones, Dr S. Shapiro for performing the immunoprecipitations, and Ms P. W. Mburu for technical assistance. This work was performed

in containment conditions specified by the NIH Guidelines for recombinant DNA research and under the supervision of the ILRAD Biohazards Committee.

Regulation of lymphocyte mitogenesis by (2′–5′) oligo-isoadenylate

Adi Kimchi, Helen Shure & Michel Revel

Department of Virology, The Weizmann Institute of Science, Rehovot, Israel

Interferon has been reported to affect cell proliferation in various tumour and normal cell cultures[1]. In human cells, the anti-growth effect of interferon is under the control of chromosome 21, like the antiviral effect[2,3], and the two activities appear to reside in the same glycoprotein[4]. In synchronised fibroblast cultures interferon inhibited DNA synthesis by blocking initiations of DNA replication[5,6]. Another system in which the inhibitory effect of interferon on DNA synthesis was particularly clear is lymphocyte mitogenesis. In lymphocytes stimulated by lectin mitogens or allogeneic cells, interferon inhibits DNA synthesis, and the RNA and protein synthesis observed before the S phase of the cell cycle[7–9]. In interferon-treated cells, several enzymes are induced, including the (2′–5′) oligo-isoadenylate [oligo(A)] synthetase E, which polymerises ATP into a series of oligonucleotides of general structure ppp(A2′p)$_n$5′A (refs 10–12). The (2′–5′) oligonucleotides inhibit protein synthesis when added to cell-free systems[10–12] or hypotonically permeabilised cells[13], and the induction of (2′–5′) oligo(A) synthetase was correlated with the antiviral action of interferon[14,15]. In the present work, the involvement of this enzyme in the antigrowth effect of interferon was studied. We show that addition of the (2′–5′) oligo(A)nucleotides to the culture medium of intact lymphocytes mimics the antimitogenic effect of interferon. Experiments with lymphocyte extracts show that, while interferon increases the (2′–5′)oligo(A) synthetase E, the mitogenic stimulus of concanavalin A leads to a decrease in (2′–5′) oligo(A) accumulation.

Table 1 Inhibition of DNA synthesis in Con A-stimulated mouse spleen lymphocytes by interferon and by (2′–5′) oligo-isoadenylate

Addition to Con A-stimulated cultures	Time of addition	DNA synthesis at 72 h ^{3}H-thymidine incorporated, c.p.m.	Inhibition (%)
Experiment 1			
None	—	111,020	0
Interferon, 200 U ml^{-1}	0 h	13,175	88
Interferon, 200 U ml^{-1}	24 h	66,050	41
Interferon, 200 U ml^{-1}	48 h	102,060	8
Experiment 2			
None	—	66,150	0
(2′–5′)ApApApA, 5 μM	0 h	17,665	74
(2′–5′)ApApApA, 5 μM	24 h	18,800	72
(2′–5′)ApApApA, 5 μM	48 h	56,765	15

Mouse spleen lymphocytes (8×10^6 cells per ml) were treated with 2.5 μg ml^{-1} Con A. Interferon (200 U ml^{-1}) or (2′–5′)ApApApA (5 μM) were added 10 min later (zero time) or at various times after Con A. DNA synthesis was measured at 72 h by a 3-h pulse of 6 μCi ml^{-1} ^{3}H-thymidine (5 Ci mmol^{-1}). Cells were then collected on glass fibre filters (Whatman GFC), washed twice with 5 ml cold PBS, twice with 5 ml 5% TCA then with 95% ethanol, dried and counted. ^{3}H-thymidine incorporated into the unstimulated lymphocytes (28,750 c.p.m.) was subtracted from that incorporated into the mitogen-treated cells.

The mitogenic stimulation of mouse spleen lymphocytes by concanavalin A (Con A) was studied. Spleens of BALB/c mice (8–10 weeks old) were teased through a metal mesh and cells were suspended in Dulbecco's phosphate-buffered saline (PBS). Erythrocytes were lysed in 0.01 M $KHCO_3$, 0.155 M NH_4Cl and 0.1 mM EDTA, and cells were washed twice with PBS. Lymphocytes were cultured at $4–8 \times 10^6$ cells per ml in RPMI 1640 medium (Gibco), or when indicated in DMEM, supplemented with 5% heat-inactivated fetal calf serum, penicillin (100 U ml^{-1}) and streptomycin (100 μg ml^{-1}). Cultures of 1 ml were incubated at 37 °C, in 5% CO_2–95% air (in 17 × 100 mm plastic tubes, Falcon No. 2051). Con A (Miles Yeda) was used at 2.5 μg ml^{-1} which gave optimal stimulation of ^{3}H-thymidine incorporation. Mouse L cell interferon was prepared and purified partially to 10^7 U per mg protein, as previously described[16].

In Con A-stimulated lymphocytes, DNA synthesis started at 48 h and was maximal by 72 h. Interferon added immediately after Con A, strongly reduced DNA synthesis measured at 72 h. The dose of interferon that caused 50% inhibition of thymidine incorporation ranged from 130 to 250 units ml^{-1} in several experiments. The inhibitory effect of interferon on subsequent DNA synthesis gradually decreased if interferon was added after the cells had been exposed to Con A (Table 1). In this experiment, when interferon (200 U ml^{-1}) was added by 24 h, the inhibition was only half of that measured at zero time, and by 48 h the inhibition was very small.

The activity of the (2′–5′) oligo(A) synthetase E was studied in stimulated lymphocytes, in conditions where interferon strongly inhibits subsequent DNA synthesis. Cytoplasmic extracts were prepared with NP40 and (2′–5′) oligo(A)synthetase measured after binding to poly(rI)·(rC) agarose. Table 2 shows that 24 h after adding interferon to unstimulated resting lymphocytes, as well as to Con A-stimulated cells, the activity of the (2′–5′) oligo(A)synthetase is increased. The basal activity without interferon was higher in these cells than that in L cells[14], but there was no difference in the basal level of unstimulated and mitogen-stimulated lymphocytes. The double-stranded RNA-dependent eIF-2 kinase Pk-i[12] was also clearly induced in the interferon-treated lymphocytes (not shown).

As interferon induces an increase in (2′–5′) oligo(A) synthetase E in the lymphocytes, we determined whether exogenously added (2′–5′) oligo(A) could mimic the inhibitory effect of interferon on DNA synthesis. Because highly charged

Table 2 (2′–5′) Oligo-isodenylate synthetase E activity in mouse spleen lymphocytes

	Poly (rI):(rC) bound fraction from	Oligo-isoadenylate synthesis [^{32}P]-(2′–5′)ApA (c.p.m.)
Expt 1	Untreated cells	3,315
	+interferon 200 U ml^{-1}	7,785
	+ interferon 100 U ml^{-1}	12,117
Expt 2	Untreated cells	1,225
	+Con A 2.5 g	1,305
	+Con A +interferon 1000 U ml^{-1}	3,910
	+interferon, 1000 U ml^{-1}	2,590

Lymphocyte cultures (4–8 × 10^6 cells per ml) in DMEM were treated for 24 h as indicated. 4 × 10^7 cells (expt 1) or 2.4 × 10^7 (expt 2) were washed twice with 35 mM HEPES buffer *p*H 7.5, 140 mM KCl, 3 mM $MgCl_2$ and lysed in 0.1 ml of 20 mM HEPES buffer *p*H 7.5, 120 mM KCl, 5 mM $MgCl_2$, 1 mM dithiothreitol, 10% glycerol (buffer B) containing 0.5% Nonidet P40 (NP40). Lysates were centrifuged for 6 min in an Eppendorf centrifuge (8,000*g*) and 20–30 μl supernatant (expt 1, 16 μg protein; expt 2, 8 μg) mixed with 25 μl packed poly(rI)·(rC)-Agarose beads (PL Biochemicals) for 5 min at room temperature. The non-adsorbed material was removed by centrifugation, the pellet washed with buffer B and 10 μl of 2.5 mM [^{32}P]ATP (3 Ci mmol^{-1}) and 2.5 mM dithiothreitol were added. The suspension was incubated 20 h at 30 °C and 6 μl of the supernatant was treated 30 min at 37 °C with 0.2 units of BAP in 30 mM Tris base. 3 μl were applied to thin layer sheets of polyethylenemine (Schleicher and Schull) and chromatographed in 0.5 M acetic acid. Enzyme E activity was determined as before[12] by counting the ^{32}P-(2′–5′)ApA formed.

nucleotides would not penetrate intact cells, we tried the (2′–5′) oligo(A) without 5′ phosphates, that is the bacterial alkaline phosphatase (BAP) resistant nucleotide cores. A series of oligomers (chemically synthesised by Rapoport and Lapidot[17]) were added to the medium of Con A-stimulated lymphocytes. Table 3 shows that (2′–5′)ApApA or longer oligomers (tetramer and pentamer) efficiently inhibit the Con A-stimulated DNA synthesis. Concentrations of 2–5 × 10^{-6} M were effective but below 1 μM the trimer had little effect on DNA synthesis in these intact lymphocytes. The effect is specific since the (3′–5′)ApApA is devoid of inhibitory activity (Table 3). Williams and Kerr[13] showed that the BAP resistant cores of (2′–5′)pppApApA were able to inhibit ^{35}S-methionine incorporation in permeabilised cells, whereas in cell-free systems of protein synthesis these BAP-treated nucleotides were inactive[10]. Possibly, the intact cell can convert the cores into the active form by phosphorylation, a function which is lost in cell-free systems.

Adding (2′–5′)ApApApA to lymphocytes 24 h after Con A stimulation was as effective as at time zero, whereas at 48 h or later the oligonucleotide did not inhibit subsequent DNA synthesis (Table 1). This suggests that (2′–5′) oligo(A) inhibits some events preceding entry into S phase.

The above experiments suggest that the increase in (2′–5′) oligo(A) synthetase E produced by interferon treatment, could mediate the inhibition of DNA synthesis in stimulated lymphocytes. When (2′–5′) oligo(A) synthetase E was measured after isolating the enzyme from the cell extract with poly(rI)·(rC)-Agarose, Con A treatment neither reduced the basal level of the enzyme in lymphocytes nor its induction by interferon (Table 2). However, Table 4 shows that extracts of Con A-stimulated lymphocytes contain an activity that inhibits the synthesis of (2′–5′) oligo(A) if added to a known amount of enzyme E. Thus, the amount of (2′–5′) oligo(A) formed by the enzyme was much smaller in the presence of extracts from Con A-stimulated lymphocytes than with those from lymphocytes maintained without mitogen. Fresh splenic lymphocytes (time zero in Table 4) also contain the inhibitor. The level of inhibitor of (2′–5′) oligo(A) synthesis is, therefore, high in lymphocytes in which DNA synthesis is active: fresh splenic lymphocytes synthesise DNA and this decreases rapidly unless a mitogen is added to the culture[18]. Similarly, the level of inhibitor of (2′–5′) oligo(A) formation decreases when the lymphocytes are maintained in culture without mitogen, but increases if Con A is added. The differential inhibition of (2′–5′) oligo(A) synthesis was maximum at 72 h after Con A stimulation, but was already marked at 48 h and even 24 h after initiating the cultures (Table 4). The nature of the inhibitor is unclear: it is heat labile and non-dialisable (not shown). Preliminary results show that extracts of Con A-stimulated lymphocytes contain an activity which degrades the oligonucleotide formed, as does the 2′-phosphodiesterase described previously[19,20].

The Con A mitogenic stimulus is, therefore, accompanied by a high level of an inhibitor of (2′–5′) oligo(A) synthesis, which could lower the basal rate of oligonucleotide formation and allow entry into S phase. This is supported by the fact that exogenous (2′–5′) oligo(A) addition inhibits entry into S phase. The effect of interferon on Con A-stimulated lymphocytes may be explained by the induction of the (2′–5′) oligo(A) synthetase E to a level which exceeds the activity of the inhibitor (the latter remained unchanged after interferon; not shown). Since cellular

Table 3 Effect of different oligonucleotides on DNA synthesis in Con A-stimulated mouse spleen lymphocytes

Oligo(A) added	Final concentration (μM)	Inhibition of incorporation of ^{3}H-thymidine (%)
None	—	0
(2′–5′) trimer	2	81

A2′p5′A2′p5′A2′p5′A2′p5′A	10	94

Mouse spleen lymphocytes (8 × 10^6 cells per ml) were treated with 2.5 μg ml^{-1} Con A and 10 min later the different oligonucleotides (chemically synthesised as in ref. 17) were added. DNA synthesis was measured at 72 h as described in Table 1. The total ^{3}H-thymidine incorporated into TCA insoluble material of 1 ml suspension in the absence of any oligonucleotide was 125,000 c.p.m. for the stimulated lymphocytes. Per cent inhibition was calculated after the values of unstimulated cells (32,800 c.p.m.) was subtracted.

Table 4 Inhibition of the (2′–5′) oligo-isoadenylate synthetase in Con A-stimulated mouse spleen lymphocytes

Lymphocyte extracts prepared at:	Inhibition of (2′–5′) oligo(A) synthesis	
	No mitogen (%)	Con A (%)
0 h	60*	—
24 h	45	60
48 h	15	60
72 h	15	80

Extracts (0.1 ml) from 5 × 10^7 Con A-stimulated lymphocytes or 10^8 untreated cells were prepared at 0, 24, 48 and 72 h as in Table 2. Cell viability in the unstimulated culture was high (>90%) throughout the experiment as determined by staining with Trypan blue. The inhibitor of (2′–5′) oligo(A) accumulation was measured as follows: Insoluble (2′–5′) oligo(A) synthetase was prepared by mixing 165 μg protein from the 0.5 M KCl ribosome extract from interferon-treated L cells[12] with 0.3 ml packed poly(rI):(rC)-Agarose as in Table 2. To 20 μl packed beads, 6 μl of 1.5 mM [α-^{32}P]ATP (3 Ci mmol^{-1}) and 10 μl of various concentrations of lymphocyte extracts (5–15 μg) were added. After 2 h at 30 °C the synthesis of (2′–5′) oligo(A) was measured as in Table 2. The inhibition was calculated for 8 μg protein extract. Without extract 2,570 c.p.m. of ^{32}P-(2′–5′)ApA was formed.

* Fresh splenic lymphocytes before culture.

RNAs activate enzyme E[17], interferon could lead to accumulation of the oligonucleotides and, as found for exogenously added (2′–5′) oligo(A), inhibit entry into S phase. It will be interesting to establish whether the inhibitor of (2′–5′) oligo(A) synthesis, described here, exists in other cells and is increased in fast growing cells. It will also be important to determine whether the antimitogenic effect of exogenous (2′–5′)ApApA results from phosphorylation of the oligonucleotide in the cell and activation of RNase F[20,21] or from some other function of these oligonucleotides. Finally, the (2′–5′) oligo(A) may become useful to regulate the immune response. [Recently, E. Martin (personal communication) reported that the (2′–5′)ApApA also inhibits DNA synthesis in cultures of lymphoblastoid Daudi cells.]

We thank Dr S. Rapoport and Y. Lapidot for the synthetic (2′–5′) oligo(A). Research supported by GSF (München, FRG) and NCRD (Israel).

Ionomycin stimulates mast cell histamine secretion by forming a lipid-soluble calcium complex

J. P. Bennett, S. Cockcroft & B. D. Gomperts

Department of Experimental Pathology, University College Hospital Medical School, University Street, London WC1, UK

The activation of cellular function following the direct introduction of Ca^{2+} into the cytosol by the use of a Ca^{2+}-transporting ionophore has served to confirm the widely held idea that Ca^{2+} has the status of a second messenger in many cell types[1,2]. However, this evidence has been obtained largely from the use of a single ionophore, the antibiotic A23187; experiments with X537A, which is another ionophorous antibiotic capable of transporting Ca^{2+} (ref. 3), have failed to show the expected characteristics. For example, histamine release from rat mast cells mediated by X537A is neither dependent on extracellular Ca^{2+} nor prevented by metabolic inhibitors[4]. Ionomycin is a recently described polyether antibiotic produced by *Streptomyces conglobatus* ATCC 31005, and is active against Gram-positive bacteria[5]. The antibiotic action is presumably due to its ionophorous properties, as it extracts Ca^{2+} from an aqueous phase into an organic phase with a stoichiometry of 1:1 (ref. 6). The ionophore is also capable of transporting $^{45}Ca^{2+}$ across biological membranes (our unpublished results). Here we report the application of ionomycin to rat mast cells. We show that ionomycin stimulates mast cell secretion solely through its ability to form a lipid-soluble calcium complex, and thus to convey Ca^{2+} across the hydrocarbon region of the cell membrane.

Ionomycin-mediated histamine secretion is completely dependent on the presence of extracellular Ca^{2+}, although, as shown in Fig. 1, the actual concentration of Ca^{2+} required varies inversely with the concentration of the ionophore used. The secretion seems to occur by the normal exocytotic mechanism, as the cells show no loss of the cytoplasmic marker enzyme, lactate dehydrogenase (<5% at 5 μM ionomycin), and secretion is prevented when cell metabolism is inhibited by preincubation for 10 min with antimycin (5 μM) in the absence of glucose.

The partial secretions induced at suboptimal concentrations of Ca^{2+} in the curves of Fig. 1 represent completed secretory events; they are not the consequence of reduced rates of exocytosis. Secretion at different suboptimal ionophore concentrations occurs at similar rates with $t_{1/2} \sim 0.6$ min and completion by 6 min (Fig. 2). At higher ionomycin concentrations (2.5 μM) secretion stops abruptly when the histamine which is available for secretion (normally about 80% of total) is exhausted.

There was little further secretion on treatment with additional ionomycin after secretion due to a first suboptimal dose was complete; this suggests that the characteristic time course for cessation of secretion reflects termination by some cellular mechanism. As shown in Fig. 2, application of 1.5 μM ionomycin in two stages (each of 0.75 μM) caused rather less secretion than 1.0 μM ionomycin at a single application. Such characteristics might result from a decrease in the sensitivity to internalised Ca^{2+} following its initial elevation due to the ionophore (for example, by the recruitment of additional Ca^{2+}-pumping or Ca^{2+}-buffering capacity) or by a termination mechanism operating at a subsequent stage in the Ca^{2+}-initiated sequence of events which lead to secretion.

Of the Ca^{2+} present in the extracellular medium, only that fraction which is present as a calcium–ionomycin complex will be able to partition into the cell membrane and thence into the cytoplasm. To estimate the size of this fraction, we used an organic extraction technique[7,8] to measure the equilibrium

$$H_2I_{org} + Ca^{2+}_{aq} \rightleftharpoons Ca.I_{org} + 2H^{+}_{aq} \quad (1)$$

H_2I and I^{2-} represent the protonated and fully dissociated forms of ionomycin, respectively. The dependence on the aqueous Ca^{2+} concentration of the amount of $^{45}Ca^{2+}$ extracted into an organic phase is shown in Fig. 3.

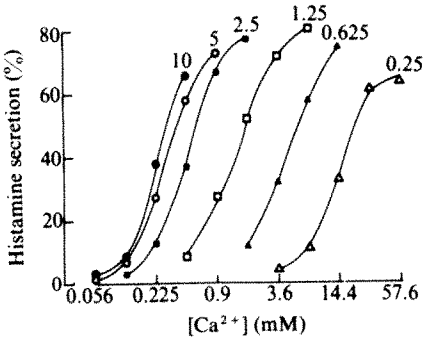

Fig. 1 The concentration dependence on Ca^{2+} of histamine secretion due to different concentrations of ionomycin. Rat peritoneal mast cells were isolated and purified as previously described[15] and suspended at $\sim 10^5$ cells per ml in a buffered salt solution, *p*H 7.5, comprising 137 mM NaCl, 2.7 mM KCl, 1.0 mM $MgCl_2$, 10 μM EGTA, 20 mM HEPES, 5.6 mM glucose and 1.0 mg ml^{-1} bovine serum albumin. Solutions were equilibrated to 37 °C before addition of 0.2 ml cells to tubes containing ionomycin and $CaCl_2$ to give the indicated concentrations in a final volume of 0.5 ml. Secretion was terminated after 10 min by the addition of 1.0 ml ice-cold phosphate-buffered saline and the cells were centrifuged at 4 °C. The histamine content in the supernatants was determined fluorimetrically[15] and is expressed as a percentage of total cell histamine. Data points represent the means of duplicate determinations which were within 10% of each other. Concentrations of ionomycin (μM) are indicated above each concentration–effect curve.

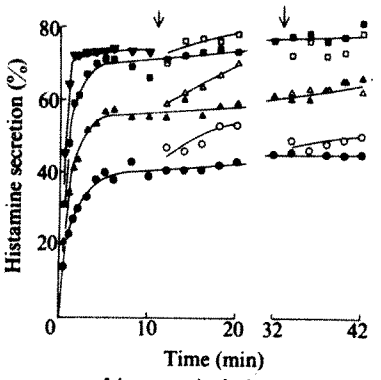

Fig. 2 Time courses of ionomycin-induced secretion. Secretion was initiated by adding 5 ml cells ($\sim 1.5 \times 10^5$ cells per ml) to buffer containing $CaCl_2$ (final concentration 1.8 mM) and ionomycin, giving a total volume of 20 ml. At the times indicated by vertical arrows, 3 ml was transferred to another tube containing additional ionomycin (in less than 10 μl) sufficient to double the concentration. Samples (0.5 ml) from these incubations were quenched at different times by addition to 1.0 ml ice-cold phosphate-buffered saline and the extent of histamine secretion was determined as in Fig. 1. Curves show time courses of secretion due to ionomycin at: ●, 0.75 μM; ▲, 1.0 μM; ■, 1.25 μM; ▼, 2.5 μM. Additional secretion due to doubling of ionomycin after the initial secretion was complete is shown: ○, 0.75–1.5 μM; △, 1.0–2.0 μM; □, 1.25–2.5 μM.

The solubility of inorganic ions in low dielectric organic phases is extremely small (ref. 1, p. 45), so the initial stage in the complexation by ionomycin is likely to occur in the aqueous phase; this can be concluded from kinetic studies[9] and from the use of fluorescent probe techniques[10] in the analogous reaction of alkali-metal ionophores. As evidence for the existence of the complex in the aqueous phase, we find a Ca^{2+}-dependent change in the UV spectrum of aqueous ionomycin, with an absorption maximum at 305 nm for the difference spectrum. Equation (1) can therefore be considered as the sum of four component equilibria

$$H_2I_{org} \rightleftharpoons H_2I_{aq} \quad (2)$$

$$H_2I_{aq} \rightleftharpoons HI^-_{aq} + H^+_{aq} \rightleftharpoons I^{2-}_{aq} + 2H^+_{aq} \quad (3)$$

$$I^{2-}_{aq} + Ca^{2+}_{aq} \rightleftharpoons Ca.I_{aq} \quad (4)$$

$$Ca.I_{aq} \rightleftharpoons Ca.I_{org} \quad (5)$$

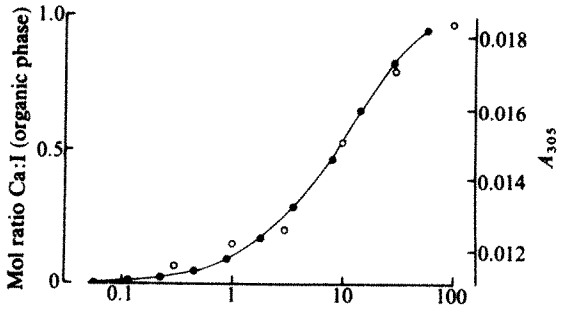

Fig. 3 Extraction of Ca^{2+} into organic phase by ionomycin. The transfer of radioactivity from an aqueous phase (the buffered salt solution described in Fig. 1 legend) containing different concentrations of $^{45}CaCl_2$ ($\sim 3 \times 10^6$ c.p.m. μmol^{-1}) into an equal volume of organic phase (toluene/butanol, 7:3) containing 20 μM ionomycin was measured as previously described[8]. The extraction of Ca^{2+} is expressed as a mol fraction of the ionomycin present (solid symbols). The figure also shows the dependence on calcium concentration of the spectral change of aqueous ionomycin. The absorbance at 305 nm was measured for ionomycin (1 μM) in 1 ml buffered salt solution (as described in Fig. 1 legend, but omitting $MgCl_2$, which also caused a spectral change, and albumin, which absorbs at this wavelength) containing different concentrations of $CaCl_2$. Higher concentrations of ionomycin could not be used because at the highest calcium concentrations visible precipitation occurred in the cuvette.

Equations (2) and (5) represent the partition coefficients of ionomycin and its calcium complex; the aqueous equilibrium is described by equations (3) and (4), with equation (3) representing the acid dissociation of ionomycin, which remains constant throughout our experiments (because we work at constant pH). The two experiments described by Fig. 3 show that the extent to which ionomycin extracts Ca^{2+} into an organic phase (closed symbols, equation (1)) is indicative of the aqueous equilibrium between the free acid and Ca^{2+} (open symbols, equation (4)), as both reactions show a similar dependence on aqueous phase Ca^{2+}.

In the buffered salt solution used in our experiments, ionomycin has a rather low affinity for Ca^{2+} (Fig. 3). Ionomycin has $pK_a \sim 8.3$ (ref. 6) so that in our buffered salt solution ($pH = 7.5$), protonation of ionomycin (equation (3)) occurs in preference to the formation of the calcium complex (equation (4)). The affinity for Ca^{2+} is very much higher at pH 10 (ref. 6). Using the data of Fig. 3 we have estimated the aqueous phase calcium–ionomycin concentration for the data points of Fig. 1 (and for another similar experiment) and the histamine secretion is plotted in Fig. 4 as a function of calcium–ionomycin.

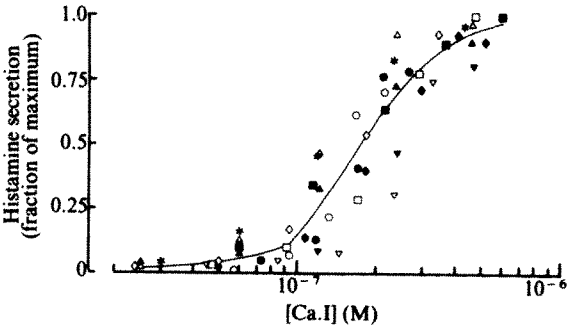

Fig. 4 The dependence of histamine secretion on the calculated concentration of calcium–ionomycin complex. The fraction of ionomycin which was present as the calcium–complex at a given $CaCl_2$ concentration (Fig. 3) was used to determine the calcium–ionomycin concentration for the data points of Fig. 1 (solid symbols) and another similar experiment (open symbols). For each experiment histamine secretion was normalised as a fraction of the maximum secretion observed. Total ionomycin concentrations were: ▼, 10 μM; ▲, △, 5 μM; *, 2.5 μM; ◇, 2 μM; ■, 1.25 μM; □, 1.0 μM; ◆, 0.625 μM; ▽, 0.5 μM; ●, 0.25 μM; ○, 0.2 μM.

The assumption that ionomycin-induced histamine secretion can be attributed to the aqueous concentration of calcium–ionomycin is supported by the data in Fig. 4. Concentration–effect curves falling over a 70-fold range of Ca^{2+} concentrations (Fig. 1) are encompassed within a twofold scatter about a curve which indicates cell stimulation over a calcium–ionomycin range of 0.1–0.3 μM. Although calcium–ionomycin has access to the cell interior, these concentrations do not represent the range over which cytoplasmic Ca^{2+} will be elevated. At the low concentrations of ionised Ca^{2+} believed to exist in the cytoplasm[11], calcium–ionomycin will rapidly and completely dissociate as soon as it enters the cell, and it is the rate of this partition process which will be a function of the external aqueous calcium–ionomycin concentration.

Our results indicate that it is the rate of entry of calcium into the cell which controls the extent (and not kinetics) of secretion. For normal (receptor-mediated) secretion, this implies that the extent of secretion will depend on the number of Ca^{2+} channels, and thus, presumably, on the number of stimulated receptors. The consequent intracellular signal could be an elevated concentration of cytoplasmic Ca^{2+}, occurring as a result of the relative kinetics of the ionophore-mediated Ca^{2+} influx and cellular Ca^{2+}-buffering mechanisms; this is likely to be of the order of 1 μM as found with other systems[12,13]. Alternatively, as Ca^{2+} influx occurs at the plasma membrane and Ca^{2+} sequestration occurs elsewhere (mitochondria, secretory granules), it could be that it is the Ca^{2+}-concentration gradient necessarily set up by the opposing effects of these two processes which acts

as the second messenger in exocytosis. A triggering role for a Ca^{2+} gradient might explain the directionality of exocytosis due to a localised stimulus[14].

We thank Dr Wen C. Liu of the Squibb Institute for Medical Research for providing ionomycin. S. C. was supported by a grant from the Wellcome Trust. Costs of the experimental work were covered by royalties accruing from publication of ref. 1.

Acetylcholine synthesis by mesencephalic neural crest cells in the process of migration *in vivo*

J. Smith, M. Fauquet, C. Ziller & N. M. Le Douarin

Institut d'Embryologie du CNRS et du Collège de France, 49bis, Avenue de la Belle-Gabrielle, 94130 Nogent-sur-Marne, France

Specific to the vertebrate embryo, the neural crest is a transitory structure whose constituent cells migrate extensively through the developing animal and ultimately give rise to many distinct cell types, including the components of the peripheral nervous system[1,2]. The earliest clear indices of their differentiation have so far been detected only when cells from the crest have reached their destination. This is exemplified by the acquisition of the ability to synthesise and store catecholamines; absent from crest cells before and during their dorso–ventral migration, this ability appears concomitantly with their aggregation into the primary sympathetic ganglia[3–6]. The chronology of cholinergic maturation, however, is less well defined. Appropriate biochemical markers are demonstrable as soon as parasympathetic or enteric ganglia are formed[7–9], but the lack of a suitable cytochemical method is a major obstacle to the identification of any cholinergic cells before then. Although acetylcholinesterase (AChE) is present in migrating neural crest[10], choline acetyltransferase (CAT), the enzyme catalysing acetylcholine (ACh) synthesis, is a much more relevant correlate[7,11,12], and definitive evidence for cholinergic differentiation should include the demonstration of ACh-synthesising activity in intact cells[13,14] or their extracts. We show here that neural crest, as soon as it begins migration, can synthesise ACh.

To overcome the difficulty of applying biochemical techniques to neural crest cells soon after they have begun to migrate, we took advantage of the fact that mesencephalic neural crest in Japanese quail embryos of 8–12 somites is clearly visible underneath the ectoderm as a sheet of cells on either side of the mesencephalic vesicle, and can be dissected out mechanically[15]. Each discrete fragment of tissue so obtained is made up of about 1,500 cells and is free from contamination by neural tube or mesenchyme (Fig. 1*b*). This system provides a unique opportunity for the preparation and study of a homogeneous population of cells actually migrating *in vivo*. Furthermore, it is equally possible to remove the mesencephalic crest at a slightly earlier stage, when it is still in the form of neural folds and migration is just beginning (Fig. 1*a*). Each crest fragment at this time contains approximately 1,000 cells.

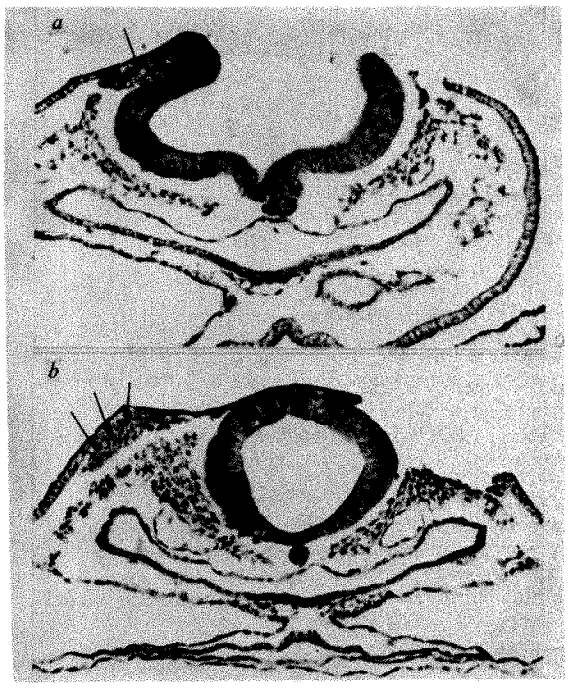

Fig. 1 Removal of the mesencephalic neural crest at the onset of, and during, the migration process in early quail embryos. *a*, Transverse section at the mesencephalic level of a quail embryo of 7 somites stained with haematoxylin. On one side, the migration of crest cells from the neural fold (arrow) is starting. At the opposite side, the crest has been cut out, together with the ectoderm, by means of a microscalpel (×110). *b*, Transverse section of a 9-somite quail embryo, stained with haematoxylin, showing the mesencephalic neural crest as a thin multi-layered sheet of cells immediately below the ectoderm. Migration is well under way. (Orthotopic grafts of quail neural tube into chick embryos[2] before the onset of crest migration have shown that the group of cells designated by the arrows on the intact side is made up of a pure population of crest cells.) Again, the contralateral crest has been excised. Note the complete and exclusive removal of the crest cells and the absence of damage to the neural tube (×110). (In this report, crest obtained from embryos of 5–7 somites is referred to as 'neural fold', that from embryos of 8–12 somites as 'migrating crest'.)

On incubation with ^{3}H-choline, isolated migrating mesencephalic neural crest formed a labelled product that co-migrated with ACh on electrophoresis (Fig. 2*b*). The identity of the radioactive material was confirmed by the demonstration that 85–90% disappeared after AChE treatment (Fig. 2*c*, *d*). Crest isolated at the neural fold stage was also able to synthesise ACh, although in significantly smaller amounts (Fig. 2*a*). Mean values (fmol per 10^4 cells) obtained for ACh synthesis and accumulation during a 4-h incubation were 7.5 ± 2 ($n = 3$) and 25 ± 5 ($n = 5$) for neural fold and migrating crest, respectively; thus, the synthetic ability is about three times greater when the crest has left the neural primordium and is fully engaged in the migration process.

ACh synthesis implies the existence of CAT, and weak but measurable CAT activity was indeed found in homogenates of migrating neural crest (Table 1). However, unequivocal determination of very low CAT levels is difficult if carnitine acetyltransferase (CarnAT) is present. This enzyme is, in fact, quite active in neural crest (Table 1, expts 3, 4). Although acetylation of choline by CarnAT is relatively inefficient[16,17], in some circumstances it may contribute significantly to ACh formation *in vitro*[18,19]. The use of CAT-specific inhibitors[20] can reveal such

Table 1 Choline acetyltransferase and carnitine acetyltransferase activities in neural crest homogenates

Expt no.	Enzymatic activity (pmol product per min per mg protein) CAT	CarnAT	% Inhibition of ACh synthesis by NVP
1	3.6	ND	45
2	5.3	ND	57
3	2.2	28.1	60
4	2.8	31.2	52

In each experiment, 68–72 migrating crests (~10^5 cells, or 15 μg protein) were ultrasonicated in 10–20 μl 50 mM sodium phosphate, *p*H 7.4, and Triton X-100 was added to a final concentration of 0.5%. For CAT assay, the reaction mixture (total volume 20 μl) comprised: 5 μl homogenate, 12.5 mM choline chloride, 300 mM NaCl, 50 mM NaF, 0.1 mM eserine salicylate, 0.1 mM [1-^{14}C]acetyl CoA (Amersham; specific activity 58 mCi mmol^{-1}) and 50 mM sodium phosphate, *p*H 7.4. Each determination was made in the presence and absence of 0.5 mM NVP (Calbiochem). Incubations were carried out in the dark at 37 °C for 30 min and the reaction was stopped by adding 5 μl *p*H 1.9 electrophoresis buffer (5 times concentrated) containing 0.1 mg unlabelled ACh chloride. ACh was separated from unconverted acetyl CoA by high-voltage electrophoresis of the whole sample (5 kV, 40 min). Radioactivity in the ACh region of the paper was measured as described in Fig. 2 legend. Assay blanks, without enzyme, were run in an identical manner. The electrophoresis step, in addition to permitting the identification of the labelled reaction product, has the advantage of giving low blanks (45–65 c.p.m. including background, corresponding to ~0.03% the initial amount of ^{14}C-acetyl CoA); each experimental value was 1.5–3 times higher than the corresponding assay blank. For CarnAT determination, 12.5 mM DL-carnitine replaced choline in the reaction mixture, nonradioactive acetylcarnitine was added at the end of the incubation and the electrophoresis time was increased to 1 h. Results have been corrected for blanks, recovery and counting efficiency. Protein was estimated by the Lowry method, using bovine serum albumin as standard. ND, Not determined.

an artefact and the results obtained with one of them, 4-(1-naphthylvinyl)pyridine (NVP), are included in Table 1. At a concentration that does not affect CarnAT in quail tissue (unpublished results), NVP reduced ACh synthesis by an average of 54%. This is probably an underestimate, as NVP is not a particularly potent inhibitor[20,21].

Despite the inference that at least half the ACh produced in cell-free preparations was due to CAT, the involvement of this enzyme in ACh synthesis in whole cells remained to be assessed. Consequently, we examined the effect of saturating concentrations of carnitine on the conversion of ^{3}H-choline to ACh by intact neural crest cells. If CarnAT was responsible for the synthesis of significant amounts of ACh, labelling of the latter should be reduced in the presence of excess carnitine. Duplicate migrating mesencephalic neural crest preparations were incubated in medium containing both ^{3}H-choline and ^{3}H-carnitine (to monitor carnitine uptake and conversion to acetylcarnitine). In one case, a large excess of unlabelled carnitine was also present. The radioactivity accumulated by the cells in choline, carnitine and their acetylated products was subsequently determined in each sample. Table 2 shows the results of an experiment in which the concentration of unlabelled carnitine was more than 1,000 times that of the radioactive precursors. It can easily be calculated that this massive dose increased the intracellular carnitine concentration by a factor of about 500; at the same time, the total radioactivity in acetylcarnitine was reduced by over 75%. In marked contrast, neither the size of the choline pool nor the labelling of ACh was significantly affected. This result clearly shows that choline and carnitine do not compete for the same enzymatic sites in intact cells and strengthens our contention that CAT is responsible for ACh synthesis in neural crest.

We conclude from these studies that mesencephalic crest cells possess a fundamental marker of cholinergic metabolism from the onset of the migratory phase of their development. This may reflect very early differentiation of the fraction of the population that will later give rise to neurones of the ciliary ganglion[22,23]. On the other hand, ACh-synthesising activity may not necessarily be restricted to presumptive parasympathetic nerve cells. It has been proposed that expression of cholinergic traits is an intrinsic property of differentiating neuroblasts, irrespective of their

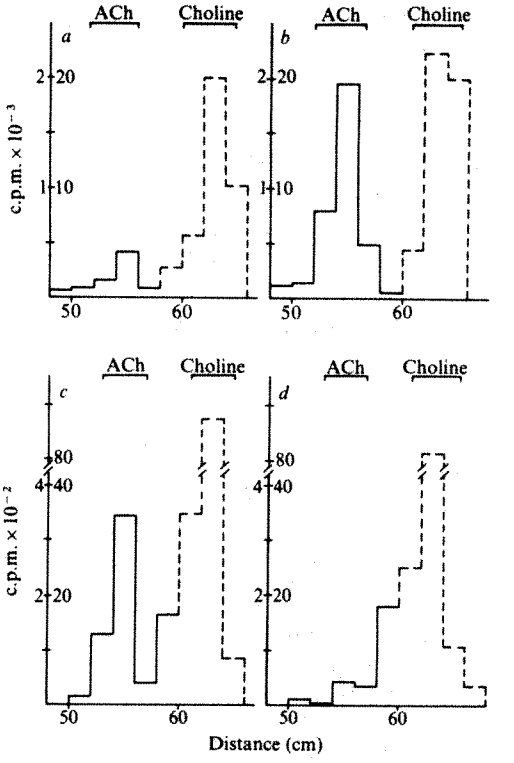

Fig. 2 ACh synthesis by excised mesencephalic crest. The technique was based on that described by Mains and Patterson[14]. The incubations were carried out in 200 μl of medium (L15 lacking choline) containing 15 μM [methyl-^{3}H]/choline (Amersham, 6.4 or 36 Ci mmol^{-1}) and 10^{-5} M eserine salicylate. After 4 h at 37 °C in humidified air, the medium was withdrawn, the tissue fragments were washed twice with cold Tyrode's solution and disrupted ultrasonically in 15 μl of electrophoresis buffer, *p*H 1.9 (ref. 13), containing unlabelled choline and ACh. The entire sample was applied to Whatman 3 MM paper and electrophoresed at 5 kV for 1.75 h (ref. 13). The positions of ACh and choline were detected with an iodine-based spray[25] and sequential, 2-cm-wide rectangles were cut out in the appropriate regions and counted in 10 ml of Beckman 'HP' scintillation fluid after elution/decolouration with 1 ml $Na_2S_2O_3$ (0.5% w/v in H_2O). Counting efficiency was 45–50%. Background values (35–50 c.p.m.) were obtained from the rectangles immediately preceding the ACh spot. The diagrams show the distribution of radioactivity migrating with ACh (solid lines, outer scale) and choline (broken lines, inner scale), the positions of the marker spots and the total distance of migration towards the cathode. *a*, *b*, Comparison of ACh synthesis by samples consisting of 20 neural folds (*a*) and 20 migrating crests (*b*). The specific activity of the ^{3}H-choline was 36 Ci mmol^{-1}. The radioactive ACh peak in *b* was not notably altered by prior purification[14] of the precursor, nor by removal of the ectoderm layer associated with the crest. *c*, *d*. Effects of AChE. The sample consisted of 50 migrating crests. After incorporation of ^{3}H-choline (6.4 Ci mmol^{-1}), the cells were ultrasonicated at *p*H 4 and centrifuged. The supernatant was adjusted to *p*H 7 and divided into two equal parts. Each was incubated for 15 min at 25 °C in the absence (*c*) and presence (*d*) of purified *Electrophorus electricus* AChE (Sigma), followed by acidification with concentrated *p*H 1.9 buffer and electrophoresis. Background counts have been subtracted.

Table 2 Effect of excess carnitine on ACh synthesis

Concentration of unlabelled DL-carnitine	Total net radioactivity (c.p.m.) recovered as: Carnitine	Acetyl-carnitine	Choline	Acetyl-choline
0	1,025	280	8,900	380
40 mM	400	65	8,300	400

Each sample consisted of 20 migrating crests (3×10^4 cells). The first was incubated in medium (L15 without choline) containing 10^{-5} M eserine salicylate, 100 μCi ml^{-1} (15 μM) [Me-^{3}H]choline and 52 μCi ml^{-1} (30 μM) DL[Me-^{3}H]carnitine (Amersham). The second sample was incubated in medium containing identical amounts of the radioactive compounds, but to which unlabelled DL-carnitine had been added to a final concentration of 40 mM, thus reducing the specific activity of the precursor from 1.7 Ci mmol^{-1} to 1.3 mCi mmol^{-1}. (Preliminary experiments had shown that extracellular carnitine concentrations of this order were necessary to increase the intracellular level sufficiently to saturate CarnAT.) After incubation for 4 h, the samples were treated as described in Fig. 2 legend, except that unlabelled carnitine and acetylcarnitine markers were added before ultrasonication and the electrophoresis time was increased to 2.25 h. In these conditions, labelled precursors and acetylated products were well separated from one another. The total radioactivity in the regions of the paper corresponding to the substances of interest was determined as indicated in Fig. 2 legend. Background values have been subtracted.

ultimate fate[24]; it might even be a feature of all neural crest cells (possibly related to the migration process[10]). This uncertainty could be resolved directly only by the development of an appropriate, unambiguous cytochemical test. In the meantime, a useful first step towards elucidating the relationship between the early cholinergic phenotype and ontogeny of the peripheral nervous system would be to determine whether crest cells from other axial levels also synthesise ACh and, if so, whether this ability is retained during at least the first stages of sympathetic and sensory ganglion formation.

Secretory activity of the anterior pituitary gland is regulated by the brain through stimulatory and inhibitory substances released from nerve endings in the median eminence of the hypothalamus and carried by the adenohypophysial portal blood system to their respective target cells. These hypothalamic influences are modulated by the feedback action of peripheral hormones. Prolactin (PRL) secreting cells are, at least partially, under the stimulatory influence of thyrotropin releasing hormone (TRH)[1,2] and of oestrogens[3]. However, they are mainly controlled by inhibitory substances among which dopamine (DA) is one of the most potent *in vivo* as well as *in vitro*[4,5]. The inhibitory effect of DA is reversed by oestrogen *in vitro*[6]. The mechanism by which these factors interact on their target cells is poorly understood. The recent discovery that anterior pituitary cells are excitable and that they are able to generate Ca^{2+}-dependent action potentials has led to the suggestion that these effects are involved in a stimulus-secretion coupling at the membrane level[7–9]. In this paper, we report that DA inhibits both the spontaneous and TRH-induced action potentials in clonal PRL pituitary cells. In addition, oestradiol-17β is able to reverse the inhibitory effect of DA.

In this study GH3 B6 cells, a subclone of GH3 rat prolactin cell line were used. These cells secrete prolactin and respond to both TRH and oestradiol[2]. Stable intracellular recordings lasting between 10 min and 1 hour were obtained from 260 cells. Of the cells tested 51% were electrically excitable and displayed action potentials when depolarised by an outward current. Twenty-six per cent of the cells were spontaneously active. These action potentials were mainly Ca^{2+}-dependent (Fig. 1*a*).

Sixty-two spontaneously firing cells were tested for an effect of DA; in 25 cells (40%), DA injected close to the cell provoked an inhibition of firing within 30–60 s (Fig. 1*c*). This inhibitory effect was preceded by a rapid decrease of the input resistance with no detectable change in the resting membrane polarisation (Fig. 1*b*); in 37 cells DA had no effect. In addition, DA inhibited

Table 1 Effect of ^{3}H-DA on PRL release and ^{3}H-DA binding in GH3 B6 cells

	Control	^{3}H-DA	^{3}H-DA + DA
PRL release (ng per mg cell protein)	283 ± 18.2	193 ± 19.8*	205 ± 6.9*
^{3}H-DA bound (d.p.m. per mg cell protein)	—	2,380 ± 196	676 ± 48

200,000 cells per 2-ml dish were grown for 5 days as previously described[10]. Before the experiment the cells were rinsed with warm Ham F10 + HEPES 20 mM, *p*H 7.2 (F10-H). They were thereafter incubated in 1 ml of fresh F10-H with or without the addition of ^{3}H-DA (16 pmol ml, 6.6 Ci mmol^{-1}) and unlabelled DA (10 nmol ml^{-1}) for 30 min at 37 °C in 95%–5% air–CO_2 humidified incubator. The incubation was stopped on ice. The cells were collected for protein assay and liquid scintillation measurement of bound radioactivity[10]. The half life of DA in such conditions was 30 min as measured in parallel dishes by J. P. Tassin (U. 114, INSERM, Collège de France) using a specific enzymatic radioassay. The medium was collected for PRL radioimmunoassay which was expressed in nanogram equivalent of rat standard RP-1 from the NIAMDD kit. Each point is the mean of triplicate ±s.e.m.

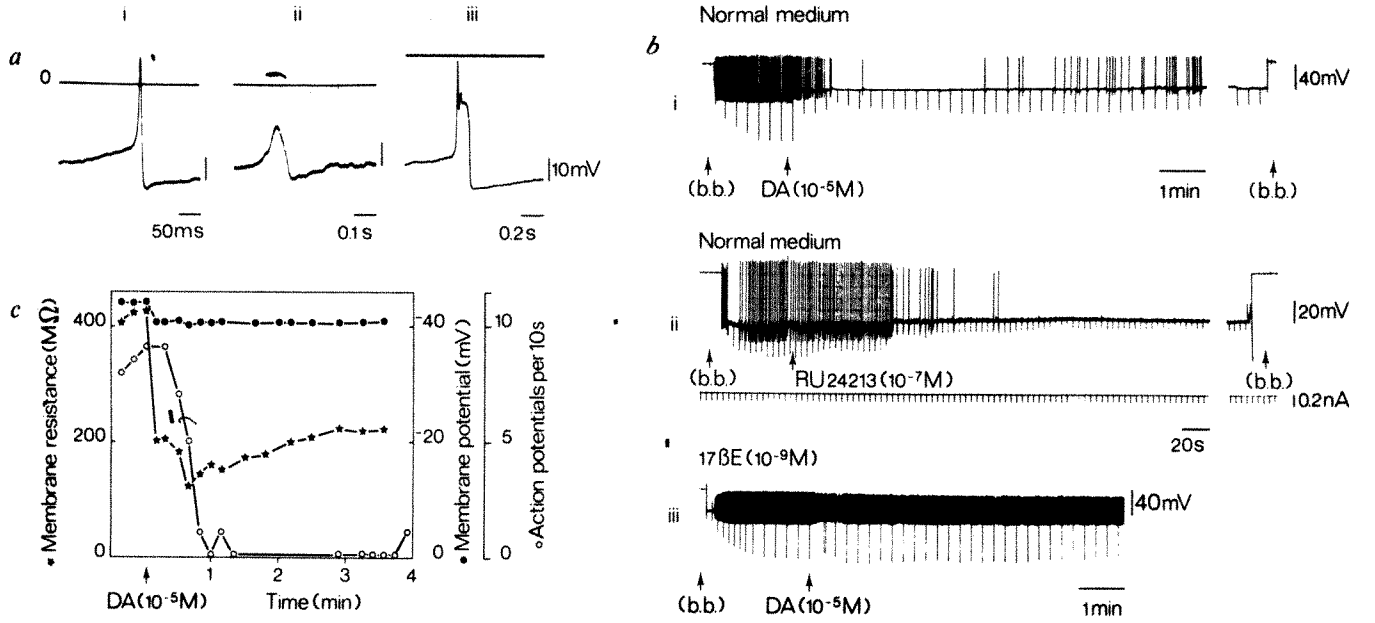

Fig. 1 Effect of DA on the firing of action potentials in the GH3 B6 prolactin secreting cell line. The cells were grown in Ham's F10 solution supplemented with 15% horse serum and 2.5% fetal calf serum. Cells were cultured for 5 to 7 days before being used in electrophysiological studies. The experiments were carried out in a temperature controlled room (26 ± 1 °C). Ten minutes before recording, the culture medium was replaced by a bathing solution with the following composition (in mM): NaCl 142.6; KCl 5.6; $CaCl_2$ 10; glucose 5; HEPES buffer 5 (*p*H 7.4). Stock solutions of oestradiol-17β(17β-E) were prepared in ethanol and diluted in the above solution; the final ethanol concentration being 0.01%; TRH (Beckmann) and DA (Hoffman-La Roche) were dissolved in bathing solution. The substances to be tested were delivered via a pneumatic ejection system which allowed rapid administration (0.5 s) of very small volume (1–5 nl) of solution from micropipettes positioned close to the membrane of the cell tested[13]. Twenty-six per cent of the cells ($n = 260$) were spontaneously active.

a, The all-or-none action potential had a positive overshoot and a prominent after-potential (i); the action potentials were reduced following the application of D 600, a known blocker of Ca^{2+} channels (ii); action potentials were still encountered in medium in which sodium chloride was replaced by choline chloride, however their size and shape were changed and no overshoot was observed (iii); the zero membrane potential is indicated by 0. *b*, The effect of DA on spontaneous action potentials. Vertical bars represent a measure of the membrane input resistance obtained by injecting a current of 0.16 nA with a bridge amplifier. i, Effect of DA on action potential firing and membrane resistance in an oestrogen depleted medium. ii, Effect of the DA agonist RU 24213 (Roussel-Uclaf) on action potential firing and membrane resistance in a oestrogen depleted medium. The current used to monitor the cell membrane resistance is shown at the bottom of the figure. In (i) and (ii) the bridge balance is indicated (b.b.). iii, Effect of DA when oestradiol-17β (10^{-9} M) was added to the recording medium. *c*, Time course of changes in membrane electrical properties following administration of DA (10^{-5} M) on the cell represented in b(i). ★, Membrane resistance; ○, frequency of firing of action potentials; ●, membrane potential.

the TRH-induced action potentials. The DA agonist RU24213 induced a response comparable to that of DA (Fig. 1*b*). In the same way as for DA, the inhibitory effect of RU24213 on action potential firing was always associated with a significant decrease in membrane resistance. Conversely, the DA antagonists haloperidol (10^{-6} M) and chlorpromazine (10^{-6} M) suppressed the inhibitory effect of DA on action potentials when they were administered to a spontaneously firing cell (Fig. 2*a*). Surprisingly, an increase in conductance occurred without any noticeable change in membrane potential. The spontaneously firing cells recorded in this study have a resting membrane potential of -45 ± 3 mV which is not near the normal equilibrium potential of any ions likely to be involved in the DA effect. The ionic nature of the currents involved in the DA effect has not yet been investigated. However, it is possible that DA increases the Cl permeability of the cell; a leakage of KCl from the tip of the KCl electrode may elevate the internal Cl concentration and bring the equilibrium potential for this ion close to −45 mV. Several arguments support this hypothesis: for example, when the resting membrane potential was displaced towards −80 mV, it was difficult to maintain a steady potential, although DA was able to induce a long-lasting depolarisation together with an increase in membrane conductance.

The DA inhibition of both spontaneous and TRH-induced action potentials may be related to the effect of DA on PRL secretion. A significant decrease of PRL release in GH3 B6 cells was induced within 30 min of exposure to ^{3}H-labelled DA (16 nM) (Table 1). Simultaneously the cells showed a binding capacity for ^{3}H-DA and this was partially inhibited by an excess of unlabelled DA (Table 1). The inhibitory effect of DA on action potential firing and the decrease in PRL secretion following exposure to DA are consistent with the stimulus–secretion coupling hypothesis. However, these two effects cannot be compared in a quantitative manner, as the method of DA application in the two experiments is different. Also, we do not know the exact amount of DA which reaches the cell membrane when DA is administered by pressure injection. We have previously shown that the DA agonist CB 154 decreased TRH-induced PRL release in GH3 B6 cells without modifying the binding of ^{3}H-TRH (ref. 10). Although these cells are of neoplasmic origin, they exhibit a binding capacity and a response to DA similar to that of normal anterior pituitary cells[5]. The fact

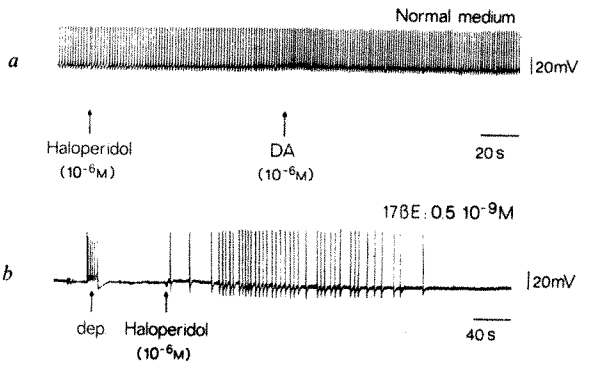

Fig. 2 Effect of haloperidol on action potential firing in GH3 B6 cells. *a*, Haloperidol (10^{-6} M) was administered to a spontaneously firing cell and antagonised the inhibitory effect of DA. *b*, Haloperidol-induced action potentials in a silent but excitable cell when oestradiol-17β (17β-E) was present in the bathing medium. The excitability of the cell was tested by a depolarisation of 0.16 nA.

that DA inhibits both the firing and hormone release supports the hypothesis that CA^{2+}-dependent action potentials are involved in the release of anterior pituitary hormone[7,8]. The mechanism by which DA inhibits the firing of PRL cells is not clearly understood. From our experiments this mechanism appears to be different from that described in central neurones[11], in that no change in the membrane polarisation was observed. Previously, we demonstrated that TRH, which stimulates the secretion of PRL, elicits action potential firing by increasing the membrane resistance without any noticeable depolarisation. These data are in agreement with the finding of Martin *et al.*[12], although Ca^{2+} ions are necessary for the secretion of pituitary hormones, depolarisation is not tightly linked to the release process. Thus, in our experimental conditions, DA appears to act on membrane excitability and resistance of GH3 B6 cells in a way opposite to TRH, although the exact mechanism involved is not known.

The percentage of cells inhibited by DA was dependent on the level of oestrogen in the growth medium. When the cells were grown for at least 24 h in an oestrogen-depleted medium, the percentage of DA-inhibited cells reached 80% (43 out of 54), compared to 40% in normal medium. When oestradiol-17β (10^{-9} M) was added to the recording solution, in all cells tested, DA had no effect on the action potential firing or input resistance ($n = 30$) (Fig. 1*c*). We have previously shown that oestradiol-17β when directly applied to the cell, provokes action potential firing[9]. DA did not inhibit this oestrogen-induced electrical activity. Moreover, haloperidol had a slight effect when added alone, and elicited a short burst of action potentials when oestradiol-17β was present in the recording solution (Fig. 2*b*); haloperidol was ineffective in an oestrogen-free solution. These results are in agreement with the recent observations by Raymond *et al.*[6] that oestrogen has a potent antidopaminergic effect on prolactin release in primary cultures of anterior pituitary cells. Furthermore, it has been recently shown that oestrogen interacts with anterior pituitary DA receptors[14]. The inhibitory effect of DA on action potential firing does not seem to be mediated by a change in membrane polarisation, and so differs from the mechanisms of action of DA so far described[11]. However, at least two classes of DA receptors have been described[15]. The first class of receptors, which increase cyclic AMP synthesis, were found in the caudate nucleus. The second class, which do not increase cyclic AMP synthesis, were described in nigro-neostriatal neurones and mammotroph cells of the pituitary[15]. Recently, Euvrard *et al.*[16] have shown that oestrogen antagonises the inhibitory responses of DA in the striatum. The GH3 B6 cell line may provide a model for the study of some postsynaptic dopaminergic systems, which are of particular interest when considering the role of dopaminergic systems in the modulation of mood and behaviour. Moreover, the model could be useful in the study of the interactions of oestrogen and DA in the control of PRL release at the pituitary level and more so, the action of oestrogen on brain function.

The stepwise methylation of phosphatidylethanolamine by two methyltransferase synthesises phosphatidylcholine in membranes[1]. Although the CDP-choline pathway is the major route for phosphatidylcholine synthesis, recent work in our laboratory has found that the methylation pathway is metabolically highly active. The phospholipid methyltransferases, their substrates and their products are asymmetrically distributed in the cell membrane. Methyltransferase I, located on the cytoplasmic side of the membrane, transfers a methyl group from *S*-adenosylmethionine to phosphatidylethanolamine to form phosphatidyl-*N*-monomethylethanolamine. Methyltransferase II, on the exterior surface of the bilayer, catalyses two additional *N*-methylations to form phosphatidylcholine. The asymmetric distribution of methyltransferases results in the synthesis and translocation of phosphatidylcholine to the exterior bilayer surface[2]. The synthesis and translocation of methylated phospholipid affects many membrane events, such as fluidity[3], coupling of the β-adrenergic receptor with adenylate cyclase[4], the number of β-adrenergic receptors[5], Ca^{2+}-ATPase activity[6], leukocyte chemotaxis[7], mast cell histamine secretion[8] and lymphocyte mitogenesis[9]. We now report that stimulation of a benzodiazepine receptor with anti-anxiety benzodiazepines, and stimulation of the β-adrenergic receptor with β-agonists, increase phospholipid methylation in C_6 astrocytoma cells. Furthermore, simultaneous addition of benzodiazepine and β-adrenergic agonists increases methylation in an additive manner.

Cultured C_6 astrocytoma cells have both β-adrenergic receptors and 'peripheral-type' benzodiazepine receptors[10]. The C_6 astrocytoma avidly binds ^{3}H-diazepam ($K_D \simeq 17$ nM) at a single and saturable class of binding sites. The 'peripheral-type' benzodiazepine receptor of C_6 astrocytoma is differentiated from the 'central-type' benzodiazepine receptor found in the cortex by their differing affinity for two ligands, Ro-5-4864 (a 4-chloro derivative of diazepam) and clonazepam. Ro-5-4864 is potent in displacing ^{3}H-diazepam from the peripheral type site ($K_i = 2.3$ nM), but is ineffective in the 'central-type' site. Clonazepam is ineffective in displacing ^{3}H-diazepam from the 'peripheral-type' site ($K_i = 2{,}000$ nM) whereas it is very potent in the 'central-type' receptor ($K_i = 0.3$ nM). The 'central-type' receptor has been extensively characterised by binding studies[11], biochemical studies[12], electrophysiological studies[13] and interactions with the GABA receptor for γ-aminobutyric acid[14]. The 'peripheral-type' benzodiazepine receptor has been characterised only by ^{3}H-diazepam binding studies.

The effect of benzodiazepines on phospholipid methylation was examined by incubating C_6 astrocytoma cells with [*Me*-^{3}H]methionine. The ^{3}H-methyl-labelled phospholipids were examined by extraction in chloroform/methanol[4]. Separation of ^{3}H-methylated products by TLC demonstrated that 70% of ^{3}H-methyl groups were incorporated into phosphatidylcholine, 5% into phosphatidyl-*N*-dimethylethanolamine and 15% into phosphatidyl-*N*-monemethyl-

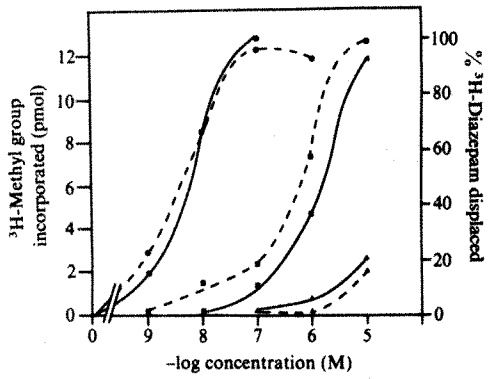

Fig. 1 Benzodiazepine receptor ligands, phospholipid methylation and displacement of ^{3}H-diazepam from the receptor binding site. C_6 astrocytoma cells (41–68 passages) were grown for 4–5 d until confluent in Dulbecco minimal essential media with 4.5 g l^{-1} glucose, 5% fetal calf serum and 4 mM L-glutamine, in FB6-TC multi-dish trays (Linbro) for phospholipid methylation assays (0.5–0.8 mg protein per well), and in Falcon flasks for ^{3}H-diazepam binding assays. The incorporation of ^{3}H-methyl groups into phospholipids was studied by aspirating the media from each well of the multi-dish tray, and adding 1 ml of Media 199 (Microbiological Associates), containing 2×10^{-4} M (±)methionine, and 30 μCi [*Me*-^{3}H]methionine (1 mCi ml^{-1}, NEN) per well. The cells were incubated for 25 min to equilibrate the isotope, and various concentrations of ligand were then added to the wells. After a 30-min incubation, the wells were washed twice with iced 0.9% NaCl. 10% Trichloroacetic acid (TCA), 1 ml, was added, the wells were scraped with a rubber policeman, and the cells transferred by pipette to test tubes. After centrifugation at 27,000*g* for 10 min the supernatant was discarded. Phospholipids were extracted from the TCA precipitate with chloroform/methanol, followed by two washes with 0.1 M KCl in 50% methanol, as previously described[1]. The organic phase, 1 ml, was evaporated in a scintillation vial, resuspended in scintillation fluid, and counted in a spectrometer. The results are expressed as pmol ^{3}H-methyl groups incorporated per 30-min incubation per well, and are the difference in ^{3}H-methyl incorporation between ligand-stimulated and control cells, in at least three separate experiments. Ligands were Ro-5-4864 (●), clonazepam (■) and chlordiazepoxide (▲). After the preincubation, 16.4 ± 4.2 pmol (s.e.m.) of methyl group were found in the phospholipids per mg protein. During the incubation in the absence of ligand for a further 30 min, 24.2 ± 2.1 pmol of methyl group were incorporated per mg protein. Variations occur in different batches of astrocytoma cell cultures, but within the same experiment, were approximately ±5%. ^{3}H-Diazepam binding was measured in membranes prepared from cells. Cells were washed twice with phosphate-buffered saline, *p*H 7.4, and scraped into 10 mM Tris HCl, *p*H 7.0, at 25 °C, homogenised by a Polytron homogeniser, and centrifuged at 40,000*g* for 10 min. The pellet was resuspended in Tris-buffer to a concentration of 2–3 mg protein ml^{-1}. The binding assay was carried out in a final volume of 500 μl, with 100 μl membrane protein, 50 μl of various competing ligands, 4 mM ^{3}H-diazepam (80 Ci mmol^{-1}, NEN) and incubated for 30 min at 4 °C. The reaction was stopped by adding 7 ml iced Tris-buffer and the solution rapidly filtered through a GF/B filter (Whatman). The filter was washed twice with 7 ml iced Tris-buffer, then counted in a liquid scintillation spectrometer. Specific binding of ^{3}H-diazepam is the difference between total binding and nonspecific binding in the presence of 10^{-5} M Ro-5-4864. In a typical experiment, 700 fmol of ^{3}H-diazepam was bound per mg protein and specific binding was 95% of the total binding. Data are expressed as the % displacement of specifically bound ^{3}H-diazepam, and are the mean of duplicate determinations. Ligands tested were Ro-5-4864 (●), clonazepam (■) and chlordiazepoxide (▲).

ethanolamine. Following preincubation of cells with [*Me*-^{3}H]methionine, incubation with benzodiazepine derivatives increased ^{3}H-methyl incorporation into phospholipids (Fig. 1). Methylation was increased by these derivatives in a dose-dependent manner. To determine whether the astrocytoma cells contain the 'central-type' or 'peripheral-type' benzodiazepine receptor, three derivatives of benzodiazepine were used. Their relative potency in increasing phospholipid was characteristic of the 'peripheral-type' receptor (Ro-5-4864>clonazepam> chlordiazepoxide). Furthermore, the potency of several benzodiazepines in stimulating methylation closely matched their potency in displacing ^{3}H-diazepam from the receptor binding site (Fig. 1).

Previous work with rat reticulocytes[4] and HeLa cells[15] demonstrated that stimulation of the β-adrenergic receptor increased the methylation of membrane phospholipids. Similarly, in astrocytoma cells, the addition of the β-adrenergic ligands increased phospholipid methylation. When astrocytoma cells preincubated with [*Me*-^{3}H]methionine were incubated with β-adrenergic agonists, the appearance of methylated phospholipids increased in a dose-dependent fashion. The capacity of these agonists to increase methylation matched for the most part their ability to stimulate adenylate cyclase (Fig. 2). A greater degree of stereospecificity was shown with phospholipid methylation than with adenylate cyclase. Their order of potency in increasing cyclic AMP levels, and in displacing ^{3}H-dihydroalprenolol from the receptor binding site (not shown) was typical for a β_1-adrenergic receptor (isoprenaline > noradrenaline = adrenaline) and exhibited marked stereospecificity ((−)isoprenaline ≫ (+)isoprenaline).

As both the benzodiazepines and the β-adrenergic agonists increase phospholipid methylation, they could be acting on the same methyltransferases or on separate domains associated with the specific receptors. If the β-adrenergic receptor and benzodiazepine receptor increased phospholipid methylation on the same enzyme, stimulating both receptors simultaneously would

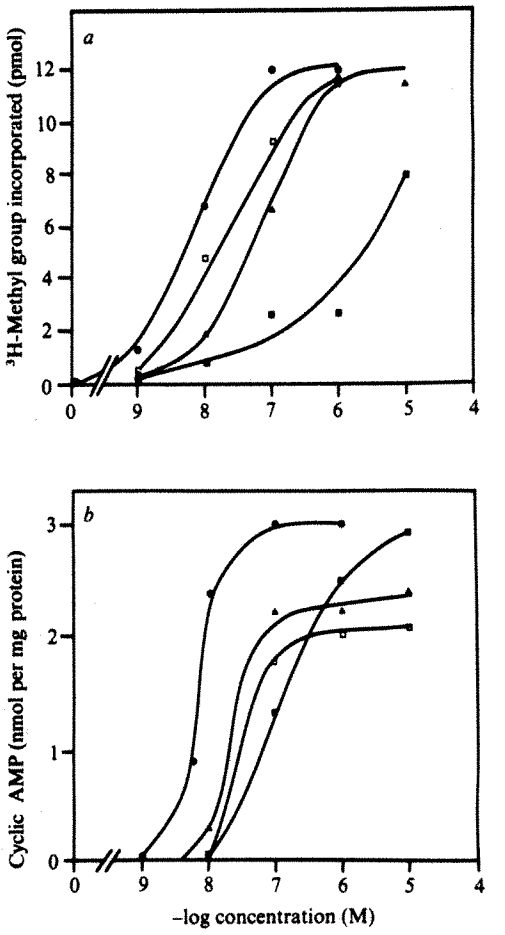

Fig. 2 β-Adrenergic receptor agonists, ^{3}H-methyl groups incorporation into phospholipids, and cyclic AMP levels. *a*, Stimulation of phospholipid by β-adrenergic agonists. C_6 astrocytoma cells were grown in multi-dish trays as previously described. Cells were incubated for 25 min with [*Me*-^{3}H]methionine, and then incubated with various concentrations of agonists for 30 min. The cells were precipitated with TCA and the phospholipids extracted and assayed for ^{3}H-methyl incorporation as described in Fig. 1 legend. The results are expressed as pmol of ^{3}H-methyl groups incorporated per 30-min incubation per well, are the difference in ^{3}H-methyl incorporation between agonist stimulated and control cells in at least three experiments. Agonists used were (−)isoprenaline (●), (−)adrenaline (□), (−)noradrenaline (▲) and (+)isoprenaline (■). *b*, Increased cyclic AMP levels following β-adrenergic receptor stimulation. Intracellular cyclic AMP levels were measured by incubating cells in multi-dish trays for 10 min in various concentrations of agonists. The incubation was stopped by aspirating the media and adding 1 ml of 0.1 M HCl. The HCl aliquot was then lyophilised and redissolved in water. The cyclic AMP content was determined by a protein binding method[17]. The data are expressed as nmol cyclic AMP per mg protein per 10-min incubation, and are the mean of duplicate determinations in two experiments. Ligands tested, and their symbols, are the same as in *a*.

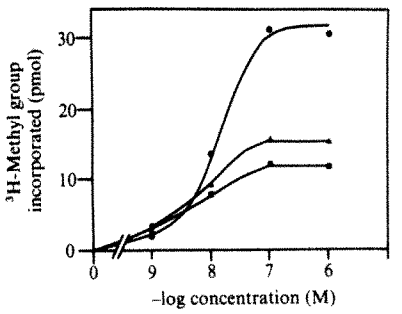

Fig. 3 Effect of simultaneous stimulation of benzodiazepine and β-adrenergic receptors on phospholipid methylation. Following preincubation with [*Me*-^{3}H]methionine, as described in Fig. 1 legend, astrocytoma cells were incubated for 30 min with increasing concentrations of Ro-5-4864 (▲), (−)isoprenaline (■) or both drugs (●). The incorporation of ^{3}H-methyl groups into phospholipids was assayed as described in Fig. 1 legend. The data are the mean of duplicate determinations of three experiments.

increase methylation no more than if either receptor were stimulated maximally. To test this possibility, the cells were treated with increasing concentrations of Ro-5-4864 or isoprenaline, or both drugs together (Fig. 3). Simultaneous stimulation of both benzodiazepine and β-adrenergic receptors increased the appearance of methylated phospholipids in an additive fashion. These results suggest that the methyltransferases are located in separate domains in the vicinity of the respective receptors. Each domain is independently affected by receptor ligands.

Previous work has demonstrated that binding of the β-adrenergic receptor by its agonists increases the methylation of membrane phospholipids[4]. The synthesis of phosphatidyl-*N*-monomethylethanolamine by methyltransferase I increases membrane fluidity[3] and enhances coupling between the β-adrenergic receptor and adenylate cyclase[4], presumably by facilitating lateral mobility of the receptor. The same effects may occur in astrocytoma cells, where β-adrenergic receptor stimulation also increases phospholipid methylation. The activities of both methyltransferases I and II are stimulated by either isoprenaline or benzodiazepines.

Little is known about the physiological or biochemical changes resulting from stimulation of the 'peripheral-type' benzodiazepine receptor, or whether the differences between the 'central' and 'peripheral' receptor reflect an intrinsic difference between these sites. Alternatively, the membrane environment of the receptor may modify its pharmacological properties[16]. The demonstration that benzodiazepine derivatives enhance phospholipid methylation is the first known biochemical event related to this receptor. As phospholipid methylation alters a variety of membrane functions, this observation may provide a rationale for additional studies of whether these 'peripheral-type' receptors have specific functions reported for the 'central-type' receptor.

How the size of motoneurones determines their susceptibility to discharge

Hans-R. Lüscher, Paul Ruenzel & Elwood Henneman

Department of Physiology, Harvard Medical School, Boston, Massachusetts 02115

The susceptibility of motoneurones to discharge by physiological inputs varies inversely with their size[1,2]. This relationship has far-reaching consequences for the control of muscular tension, and also accounts for significant differences in the properties of muscle fibres and motor units[3–5]. The probable basis for the relationship is that the amplitude of excitatory postsynaptic potentials (e.p.s.ps) is also correlated inversely with cell size[6,7], but no satisfactory explanation for this finding is known. We now describe experiments which indicate that afferent impulses invade the relatively simple ramifications of fibres going to small motoneurones more completely than the extensive arborisations going to large cells. This results in activation of a higher percentage of the synaptic endings on small cells, which produces larger e.p.s.ps in them and accounts for their greater susceptibility to discharge.

Experiments were designed to test the following hypothesis. As motoneurones of different sizes reportedly have equal densities of synaptic boutons[8], those with large surface areas must have proportionally more boutons. In particular, if large motoneurones supplying the medial gastrocnemius have more endings from Ia fibres coming from that muscle, this is due, not to the fact that they receive projections from more Ia fibres, but to the more extensive arborisation of individual Ia fibres on these cells, because each motoneurone receives terminals from essentially all Ia fibres coming from its muscle[9]. The more numerous branch points, terminal boutons and *boutons en passant* in extensive arborisations presumably lower the safety factor for propagation[10]. Experimental evidence indicates that

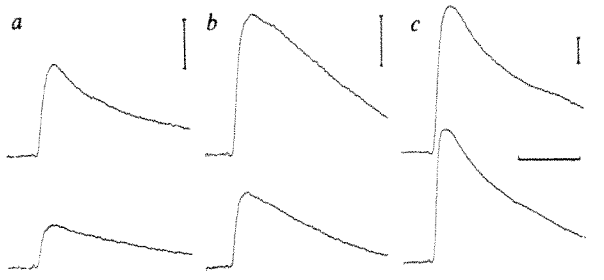

Fig. 1 Examples of aggregate e.p.s.ps recorded from three medial gastrocnemius motoneurones to illustrate the effects of post-tetanic potentiation on cells of different size. Microelectrodes with resistances of 3–10 MΩ were used to record intracellular potentials of motoneurones in cats deeply anaesthetised with sodium pentobarbital. After locating intraspinal regions where antidromic volleys in the axons of MG motoneurones evoked large electrical 'fields', the ventral roots were severed to eliminate motoneurone backfiring which interferes with the recording of their e.p.s.ps. The input resistance of each penetrated cell was obtained by measuring the effects of hyperpolarising and depolarising currents on the amplitudes of antidromic spikes (spike height method)[16]. Eighteen measurements at nine levels of current injection were made. Only cells yielding linear plots of spike height against current were accepted for definitive study. Each of the lower records is the average of 16 monosynaptic, aggregate e.p.s.ps elicited by brief 1 s^{-1} shocks supramaximal for all Ia fibres in the gastrocnemius nerve. After these control responses had been obtained, the muscle nerve was stimulated at 500 s^{-1} for 10 s and e.p.s.ps were again recorded at 1 s^{-1}. The averages of the 3rd to the 18th e.p.s.p. after these tetani are shown in the upper traces. Increases in the size of these e.p.s.ps are of presynaptic origin, being associated with hyperpolarisation of the Ia fibres following a tetanus[15]. The present study suggests that hyperpolarisation enhances local current flow during action potentials, facilitating invasion of terminal arborisations and activating more synaptic knobs. Vertical scale bars, 2.0 mV; horizontal scale bar, 5.0 ms; *IR* values: *a*, 0.3 MΩ; *b*, 1.1 MΩ; *c*, 3.0 MΩ.

an impulse in a motor axon may fail to invade all its branches[11] and that transmission failures may occur in Ia synapses on motoneurones[12]. It follows that the larger a motoneurone is, the more extensive are the terminal arborisations on it. Therefore, the possibility that impulses in them will die out at certain points will be correspondingly greater and the percentage of Ia endings that are activated by maximal volleys in Ia fibres will be smaller. Anything that facilitates invasion of Ia terminals and activation of synaptic endings should lead to larger aggregate e.p.s.ps and this tendency should be greater in large than small motoneurones.

To test this hypothesis, intracellular recordings were made from motoneurones of anaesthetised cats. First, the input resistance (*IR*) of each motoneurone was measured to provide a reliable estimate of its size[13,14]. Then, the medial gastrocnemius nerve was stimulated at 1-s intervals with brief shocks that set up afferent volleys in all its Ia fibres. The monosynaptic e.p.s.ps evoked by them were recorded and a series of 16 of these responses were averaged electronically and written out on an *x–y* plotter. The muscle nerve was then tetanised at 500 s^{-1} for 10 s and a post-tetanic series of e.p.s.ps was recorded and averaged. Lloyd[15] showed that conditioning tetani of this frequency and duration caused hyperpolarisation of the Ia fibres and a dramatic increase in the amplitude of the monosynaptic reflexes elicited by volleys in them. This 'post-tetanic potentiation' (p.t.p.) fell gradually to control levels within 2–3 min.

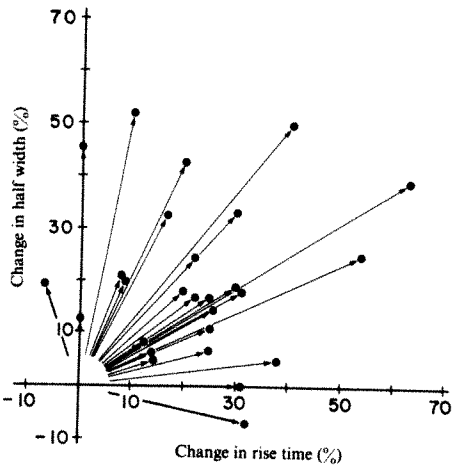

Fig. 3 Plot of changes in rise times of e.p.s.ps against changes in halfwidths following a tetanus to the muscle nerve at 500 s^{-1} for 10 s. Arrows indicate directions of change. The time courses of e.p.s.ps in these experiments were sometimes altered by afferent impulses in group II fibres, which also project monosynaptically to motoneurones[17]. The data plotted here were obtained from records where there was no evidence of group II inputs, but the possibility of a contribution from them could not be eliminated entirely.

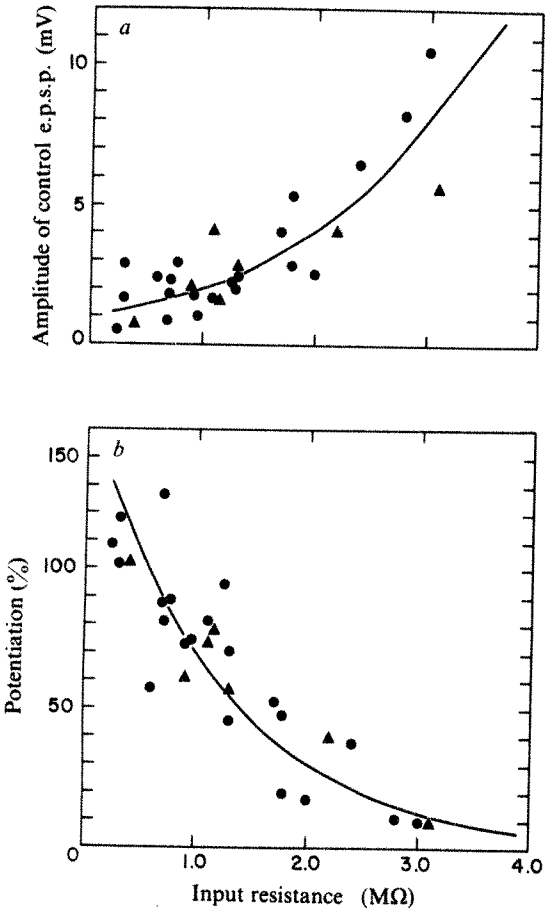

Fig. 2 Relationship between input resistances of motoneurones (in MΩ) and amplitudes of their aggregate e.p.s.ps (in mV) before (*a*) and during (*b*) post-tetanic potentiation. Data were pooled from nine experiments. Measurements from a few semitendinosus motoneurones (▲) are plotted with those from medial gastrocnemius (●) to illustrate the essential similarity of the relationship for both species of motoneurone. Comparison of *a* and *b* indicates that motoneurones with the largest control e.p.s.ps exhibited the least potentiation and those with the smallest control e.p.s.ps were potentiated the most, as our hypothesis predicts. The exponential curves through the two sets of data points were plotted by the method of least squares.

Figure 1 shows typical effects of p.t.p. on the e.p.s.ps of three motoneurones of different sizes. The lower traces in the three pairs of records illustrate that the average size of the aggregate e.p.s.ps before potentiation varied directly with the *IR* of the motoneurone (see values in legend to Fig. 1). This confirmed previous observations[7]. The upper traces are the averages of 16 e.p.s.ps following the tetanus. The per cent potentiations in *a*, *b* and *c* were 123, 92 and 11, respectively.

Figure 2*a* plots the relationship between input resistance and amplitude of control e.p.s.ps in data pooled from nine experiments. Figure 2*b* illustrates the way in which per cent potentiation was related to input resistance in the same experiments. As our hypothesis predicts, the greatest potentiation occurred in motoneurones with the lowest *IR*, that is, in the largest cells. The least potentiation and the largest control e.p.s.ps were found in motoneurones with the highest *IR* values. Less branching would be expected in Ia fibres approaching these small cells and few inactive endings should be available to increase synaptic input during p.t.p. It has generally been assumed that p.t.p. is due to release of more transmitter from a fixed number of active endings. This assumption, however, would predict that the effect of p.t.p. is independent of cell size and is no longer tenable.

If our hypothesis is correct, p.t.p. might be expected to cause small increases in the conduction time required for Ia volleys to invade additional terminals and to activate more synaptic knobs. The flow of synaptic currents at the various endings might be less synchronous, that is, more prolonged due to these delays[10], but it is difficult to predict the effects of p.t.p. on the time course of e.p.s.ps without precise information about the geometry of the terminal arborisation of Ia fibres. Figure 3 plots the changes in rise time in e.p.s.ps against the changes in their halfwidths during p.t.p. In general, rise times and halfwidths increased during p.t.p. as predicted, but the magnitudes of these changes do not seem to be related (see Fig. 3 legend).

These experimental findings are consistent in all respects with our proposed hypothesis. They suggest that invasion of Ia terminals is a graded process that is generally more complete in the terminal arborisations on small cells because they have fewer branch points. The percentage of Ia boutons that are activated by afferent impulses depends on this process. The surface area that a motoneurone presents to approaching Ia fibres may influence their tendency to branch and, thus, indirectly determine its own susceptibility to discharge.

Activation of pre-existing but inactive synaptic endings, which our findings imply, provides the functional equivalent of

new connections. Experiments to determine whether a similar mechanism, with a more prolonged time course, is used in the circuits involved in memory and learning might offer promising leads.

Single ionic channels observed in tissue-cultured muscle

Deborah J. Nelson & Frederick Sachs

Department of Pharmacology and Therapeutics, State University of New York at Buffalo, Buffalo, New York 14214

The extracellular patch clamp technique developed by Neher *et al.*[1] to record the responses of single channels in skeletal muscle has provided firm evidence for the two-state nature of the conductance event in nicotinic endplate channels. We report here the use of the extracellular patch technique to record single-channel responses from tissue-cultured chick skeletal muscle cells. The temperature dependence of channel conductance and gating kinetics shows no evidence of discontinuous behaviour between 17 and 37 °C.

The ability to record single-channel responses makes it possible to investigate properties of excitable cells which are otherwise inaccessible. Fischbach and Lass[2], have reported that in a tissue-cultured preparation of chick 'myoballs', the single-channel conductance (as estimated by fluctuation methods) increased with temperature to about 20 °C, and then remained constant at about 30 pS. The channel open time, as estimated by the half-power frequency of the fluctuation power spectrum, did not show any abrupt change with temperature. Their data present two simple alternative interpretations: (1) that there are two or more populations of channels, high conductance and low conductance, which change proportions as a function of temperature; or (2) that the whole population of channels shows identical, discontinuous, responses to temperature. Using kinetic techniques, the first alternative cannot be distinguished from the second as the populations are apparently kinetically indistinguishable. However, the problem could be solved if the response of the individual events could be resolved.

Using 100 nM suberyldicholine as an agonist, we measured single-channel responses in cells at rest and in cells in microelectrode voltage clamp conditions. Suberyldicholine was chosen as the agonist as its channel open time is longer than that for other agonists. A typical record of channels observed in an unclamped cell is shown in Fig. 1. The salient features of the record are similar to the results reported for frog muscle[1,3]. Two-state current pulses of inward current, shown as downward deflections, are the most striking features. We calculated the single-channel conductance assuming a reversal potential of

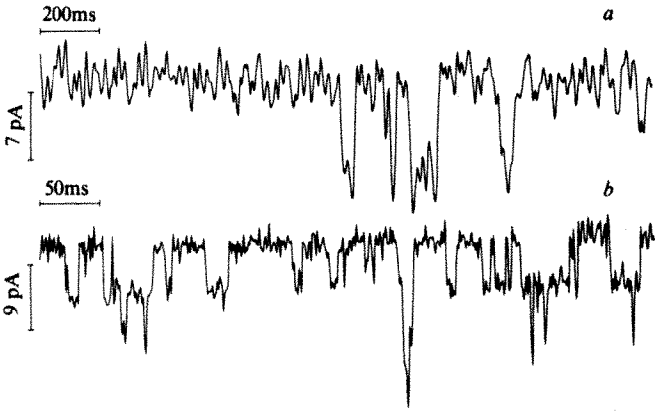

Fig. 1 Digitised membrane current traces showing pulse-like agonist-activated current flow through single channels. Downward deflections indicate inward current. Both records were filtered at a bandwidth of 280 Hz. *a*, 23.5 °C, membrane potential −49 mV, at rest. *b*, Different cell, 38 °C, membrane potential −102 mV, under voltage clamp. Cultures were prepared from 10–12-day-old Leghorn embryos using mechanical disaggregation in divalent ion-free phosphate-buffered saline[4]. The cells were plated on gelatin coated plastic tissue culture dishes in Dulbecco's modified Eagle's medium containing 10% heat inactivated horse serum and 2% embryo extract. The cells were treated with 10 μM cytocine arabinoside to prevent overgrowth of fibroblasts[14]. For experiments, the dishes were filled with HEPES-buffered Hank's saline containing 10% heat inactivated horse serum covered with a layer of mineral oil, and placed on the temperature-controlled stage of an inverted, phase contrast microscope. Single-channel records were made either on cells at rest with an intracellular microelectrode to record potential or in voltage clamp conditions using a standard two microelectrode voltage clamp. Extracellular patch recording pipettes were made according to techniques described by Neher *et al.*[1]. The pipettes were filled with Hanks' saline containing 50–100 nM suberyldicholine. Pipette resistances varied from 1–5 MΩ in solution, increasing to 3–20 MΩ when placed against the cell surface. The patch recording system was essentially the same as described previously[1] with the addition of an automatic drift compensation circuit (E. Neher, unpublished) and an internal calibration circuit. Data were recorded on analogue magnetic tape for later analysis.

0 mV and a linear current voltage relationship[4,5]. At 22 °C we calculated a mean channel conductance of 60 pS (compared with 48 pS observed by Jackson and Lecar[5]). Working with frog extrajunctional receptors, Neher and Sakmann[6] estimated the single-channel conductance to be about 15 pS at 8 °C. Even if a Q_{10} of 1.5 is assumed, the conductance is significantly lower than the values reported here for homeotherms. In adult rat, Sakmann[7] has reported a channel conductance at 22 °C of 34 pS at the endplate, and 25 pS extrajunctionally. The tissue-cultured preparations seem to have a larger channel conductance than the adult tissues.

The open channel duration is an exponentially distributed random variable (Fig. 2). The mean channel open time was estimated as the time constant of an exponential least squares fit to the duration histogram. Using suberyldicholine, the mean time constant of channel closing was 13 ms at 24 °C. This should be compared to 3 ms observed in tissue-cultured rat muscle with carbachol as an agonist[5]. Using fluctuation and voltage jump relaxation methods, Neher and Sakmann[8] have estimated the mean channel open time at 18 °C in the frog to be 0.5 ms with carbachol and ~4 ms with suberyldicholine. Thus, it is clear that carbachol as an agonist is less efficient than suberyldicholine in keeping channels open. At the same temperature, both carbachol and suberyldicholine appear to keep channels open for relatively longer periods in homeothermic preparations than in poikilothermic preparations. When examined over a range of temperatures, the single-channel conductance and open time behave simply (Fig. 3). The variation of channel conductance with temperature is shown in Fig. 3*a*. Channel conductance

0028-0836/79/510861—03$01.00

© 1979 Macmillan Journals Ltd

increases with increasing temperature with a Q_{10} of 1.3. The channel conductance variation with temperature is similar to the Q_{10} of 1.7 reported earlier from fluctuation analysis using acetylcholine[4]. Contrary to the results reported by Fischbach and Lass[2], we see no levelling off of the conductance at high temperatures, or any evidence of discontinuous change in conductance with temperature. The single-channel results are unambiguous in showing a high conductance at body temperature. The temperature dependence of the mean channel open time is shown in Fig. 3*b*. The enthalpy of activation, as calculated from the slope of the regression line, was 4.4 kcal mol^{-1}. If we combine data from fluctuation measurements[4] and the present work, a curious pattern emerges whereby the activation enthalpy of the closing rate is inversely correlated with the open time. This may reflect entropic contributions to the activation energy for closing or perhaps a more complicated interaction of the rates for agonist binding and channel open-closed isomerisation.

Some records showed what appeared to be multiple gating of a single channel (Fig. 4). In these records the mean opening rate was low (duty cycle = 0.03) and hence there was a low probability of finding more than one channel open at a time. Nonetheless, we observed many events similar to those shown in Fig. 4 in which a channel apparently turns on and off several times before closing 'for good'. This burst-like behaviour is similar to that reported by Patlak *et al.*[9] for desensitised channels and by Neher and Steinbach[10] for endplate channels treated with local anaesthetics. As the opening rate and the agonist concentration were low, high probability agonist binding does not seem to be the cause of the multiple gating events. Perhaps suberyldicholine as a bivalent agonist, is able to block the same channels it activates[11], or the agonist dissociation rate is comparable to the channel opening rate so that several open–closed cycles may take place before agonist dissociation[12]. Further work needs to be carried out to elucidate the mechanism of this repetitive behaviour.

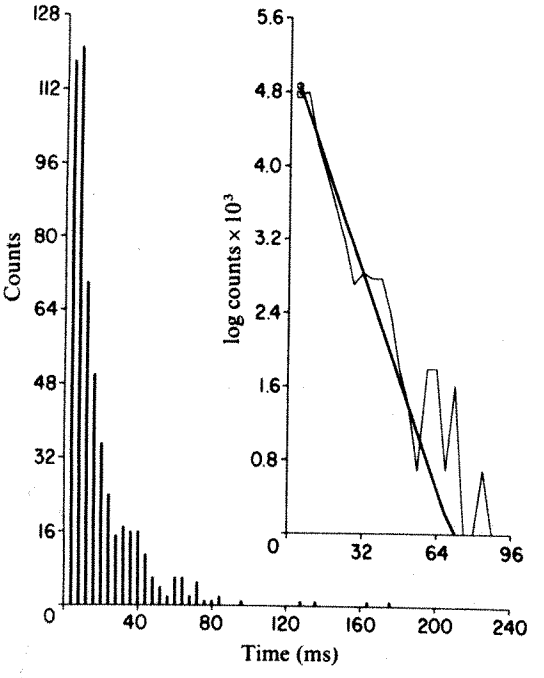

Fig. 2 Histogram of single-channel durations. Figure 1*a* is a typical segment of the data used to construct the histogram. Inset shows the same data plotted semilogarithmically and fitted with a single exponential (heavy line) by a least squares fit routine. Both amplitude and duration histograms were calculated from the raw data by an automatic pattern recognition program (F.S. and N. Barkakati, in preparation).

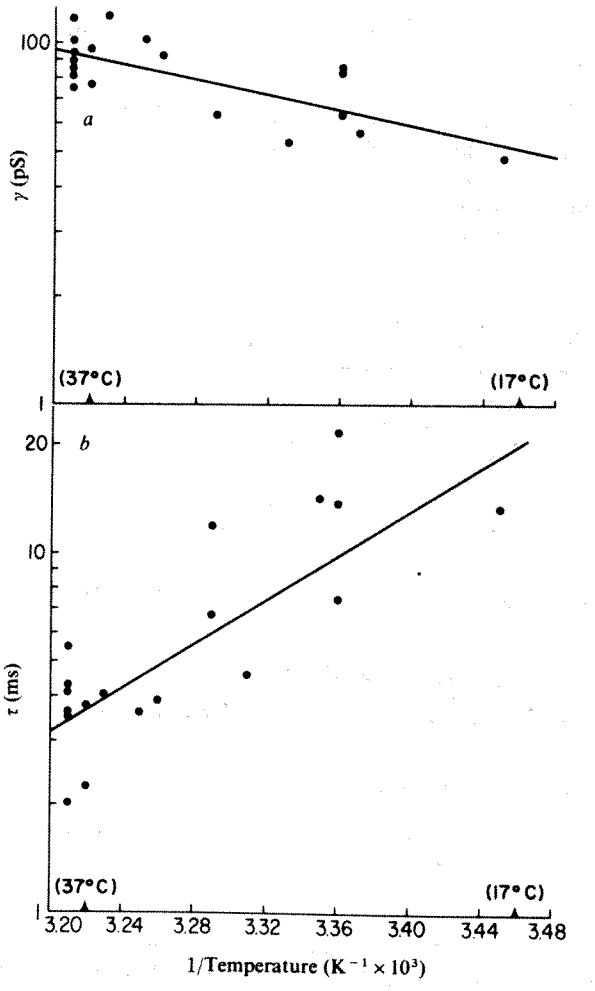

Fig. 3 Arrhenius plot of the single-channel conductance (*a*) and mean channel open time (*b*). Each point represents the results of measurements on an individual cell. *a*, Single-channel currents used to calculate conductance were obtained from amplitude histograms in accordance with a model which predicts the shape of the histogram and takes into account the fact that the wall thickness of the patch pipette is not negligible (channels which lie under the rim of the pipette do not contribute a full share of current to the observed record (F.S. and N. Barkakati, in preparation). The solid line is a least squares regression with a slope equivalent to an enthalpy of activation of 2 kcal mol^{-1}. *b*, Mean open times from individual cells were obtained from duration histograms. The line, which represents a least squares regression fit to the data, corresponds to an enthalpy of activation of 4.4 kcal mol^{-1}.

This work demonstrates that single-channel recording techniques can be easily extended to a wider variety of preparations than previously reported. More specifically, we find no anomalous temperature dependence of channel conductance. Results presented here were obtained on myotubes not treated with vinblastine, so that vinblastine treatment cannot account for the discrepancy between the results of Fischbach and Lass[2] and the results presented here. The origin of the discrepancy remains obscure, but we are reticent to ascribe the differences to

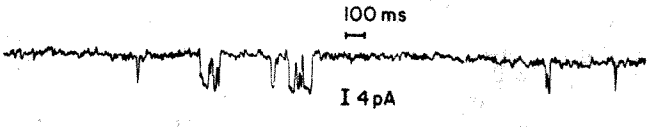

Fig. 4 Chart recording of membrane current illustrating the occurrence of apparent multiple gating of a single channel (see text for details). Temperature, 27 °C; bandwidth, 100 Hz.

the slight variations between the preparations, as these results agree reasonably well with the earlier results obtained with fluctuation analysis on vinblastine-treated cells, as well as with earlier data on myotubes using acetylcholine as an agonist[13].

We thank Dr E. Neher for advice, Dr J. Heesemann for supplying suberyldicholine, R. McGarrigle for technical assistance and N. Barkakati for programming assistance. This work was supported by NS 13194, HL 21294 and the Muscular Dystrophy Association.

Single postsynaptic channel currents in tissue cultured muscle

Meyer B. Jackson & Harold Lecar

Laboratory of Biophysics, IRP, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health, Bethesda, Maryland 20205

Some of the most compelling evidence for the existence of ionic channels in cell membranes comes from direct recording of quantised current jumps generated by the opening and closing of individual channels. Single-channel jumps have been extensively studied for lipid bilayer membranes doped with various channel-forming additives[1]. Recently agonist-induced single-channel currents were detected in denervated frog muscle by use of extracellular electrodes, which can isolate the current from a small area of membrane[2]. The current jumps provide a means for the direct test of many of the inferences about ionic channels which have come from electrical noise analysis[3,4]. In this report we present measurements of single-channel currents induced by the agonist carbamylcholine in tissue-cultured mammalian muscle. These measurements confirm the earlier noise studies on tissue culture preparations[5,6]. Recordings of single-channel currents induced by the agonist, suberyldicholine, in avian muscle are presented by Nelson and Sachs[7].

The methods used for single-channel recording have been described by Neher *et al.*[8]. A small ($\sim 1\ \mu m^2$) patch of cell surface is isolated with a specially fabricated extracellular glass microelectrode. A low-noise circuit amplifies the current through this patch of membrane. The signal is then recorded on a digital oscilloscope and can be stored on tape for later analysis. Dissociated embryonic rat muscle was grown according to the procedure of Nelson *et al.*[9].

Figure 1 shows channels recorded from a cell held at a membrane potential of -90 mV. From such recordings, the single-channel conductance and the open-channel durations are measured directly. Figure 2*a* shows a histogram of the distribution of open-channel lifetimes. The number of channels remaining open for a time greater than T is plotted against T. The semilogarithmic plot of open-channel durations fits well to a single-exponential distribution, consistent with the notion that the closing of the channels is a process having a Poisson distribution. The mean channel open time at a temperature of 22 °C is 3.2 ms.

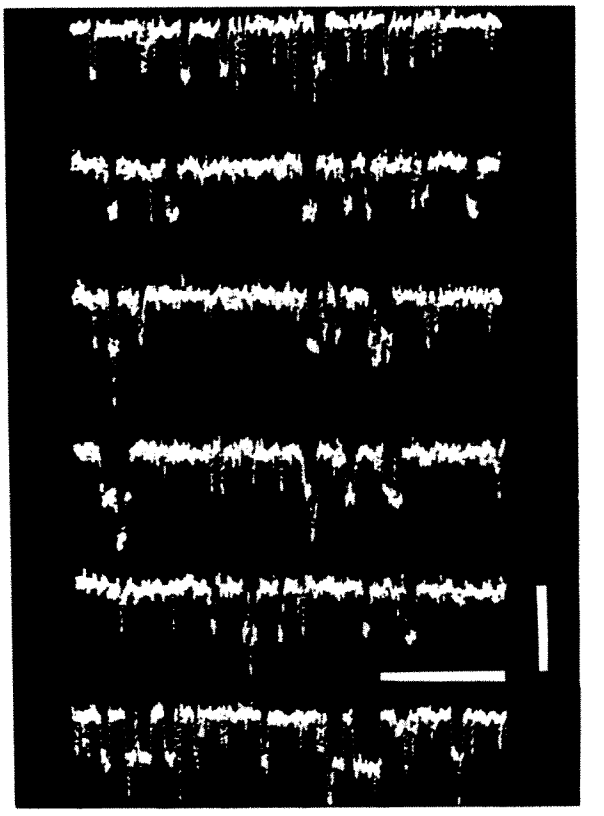

Fig. 1 Channel records made from cultured rat muscle at 22 °C. The muscle was bathed in Dulbecco's phosphate-buffered saline, with tetrodotoxin added to prevent spontaneous contraction. The currents were recorded from a thick-walled glass micropipette fabricated with a deFonbrune microforge. This micropipette was filled with saline and 1.0 μM carbamylcholine. Its resistance was 3 MΩ and increased to 40 MΩ when pushed against the cell surface. The cell was hyperpolarised to -90 mV using two intracellular electrodes, one to pass current and the other to record the cell membrane potential. Scales: horizontal, 100 ms; vertical, 10 pA.

The mean single-channel current at -90 mV is 4.4 pA, indicating that the unit channel conductance is 49 pS (assuming a reversal potential of zero for the postsynaptic channel). The standard deviation obtained from the channel current amplitude distribution is 0.8 pA. The two main reasons for this spread are the intrinsic current noise of the wide bandwidth amplifier needed to record the short-lived events and the recording of undersized current jumps from channels situated beneath the annulus of the pipette.

As a check on the straightforward but tedious determination of individual channel amplitudes and durations, we also used simple automated procedures to obtain these parameters. Amplitude histograms were made directly from the data using a computer program. Figure 2*b* inset shows a current amplitude histogram using 4,096 points spaced 200 μs apart. The direct histogram shows three peaks, a large gaussian distribution of baseline noise centred at zero, a second peak about the single channel amplitude, and a third smaller peak at twice the single-jump amplitude. The channel current can be estimated from the displacement of the secondary peaks without the necessity of analysing individual events. The weighting of events is different here than for the direct measurement, as a long-lived event will contribute more points to the histogram than a shorter event. Using the amplitude histograms, we obtained a single-channel current–voltage curve (Fig. 2*b*). The plot of current peaks versus applied membrane potential is linear over the voltage range measured. From the slope of the line, we obtain a unit conductance of 48 ± 0.4 pS.

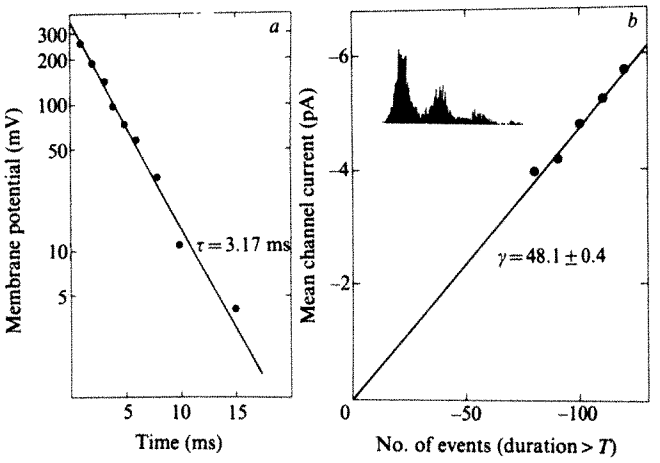

Fig. 2 *a*, A semilogarithmic plot of the number of events with duration greater than time T plotted against T shows the exponential probability of channel open time. The line is a least squares fit to the data. *b*, Single-channel current-voltage curve. Abscissa gives holding potential with increasing hyperpolarisation to the right. Ordinate shows inward current as determined from the second peak of current histogram. Inset, a typical current histogram, taken at a holding potential of −100 mV. The histogram is determined from a record of 4,096 points taken at 200-μs intervals; the horizontal distance between the first two peaks is 4.8 pA and the vertical displacement is proportional to the number of points with a given amplitude.

To analyse channel lifetimes automatically, a Fast Fourier Transform program was used to determine the power spectra of digitised records similar to those shown in Fig. 1, but usually with a higher density of channel events. The power spectra are lorentzian, as expected from the underlying Poisson random process. The mean channel durations determined from the cutoff frequencies of the noise spectra were in agreement with the values determined from the pulse-duration histograms. Thus, spectral analysis methods can be used as a convenient method to analyse stationary records of single-channel jumps.

Single-channel measurements seem to be feasible for a variety of tissue-cultured excitable cells, and the patch-electrode method allows one to observe the ion channel activity in an area of a heterogeneous membrane of less than 5 μm^2. Preliminary measurements carried out in collaboration with C. N. Christian indicate that the distribution of channel density determined with an extracellular patch electrode coincides with that obtained by observing the same cells in a fluorescence microscope using rhodamine labelled α-bungarotoxin[10].

We thank M. Neale for preparing the rat-muscle cultures, W. Vaughan and W. Sheriff for the computer programs, F. Sachs for many helpful suggestions and C. N. Christian and P. G. Nelson for their encouragement and instruction in tissue-culture techniques.

Nucleotide sequence analysis of the chloramphenicol resistance transposon Tn*9*

N. Kirby Alton & Daniel Vapnek

Department of Molecular and Population Genetics, University of Georgia, Athens, Georgia 30602

The transposable genetic element Tn*9* consists of two direct repeats of the insertion sequence IS*1* flanking a region of 1,102 base pairs which determines chloramphenicol resistance[1,2]. Transposition of Tn*9* leads to the duplication of a 9-base pair sequence which preexists at the site of insertion. One copy of this sequence is found at each end of the inserted element[3]. The chloramphenicol resistance determined by Tn*9*, and by various other R plasmids, is due to the synthesis of the enzyme chloramphenicol acetyl transferase (CAT)[4,5]. This enzyme catalyses the formation of acetylated derivatives of chloramphenicol which are inactive as inhibitors of protein synthesis[5]. By using the chain termination technique of DNA sequencing, we have now determined the nucleotide sequence of the 1,102 base pair region between the directly repeated IS*1* sequences in the bacterial transposon Tn*9* (encoding chloramphenicol resistance). The amino acid sequence of CAT predicted from the nucleotide sequence is identical to that determined by Shaw and coworkers[6]. An analysis of the sequence suggests that the internal 1,102 base pair region is not directly involved in transposition.

Restriction endonuclease analysis of bacteriophage P1Cm DNA demonstrated that Tn*9* contained unique *PstI* cleavage sites within the directly repeated IS*1* sequences but no *PstI* sites within the chloramphenicol resistance determinant[7]. Cleavage of bacteriophage P1Cm with *PstI* generated a fragment of 1,870 base pairs. This fragment contained the 1,102-base pair region encoding the structural gene for CAT flanked by 588 base pairs from the right end of IS*1* and 180 base pairs from the left end of IS*1*. The 1,870-base pair fragment was cloned in the *PstI* site of plasmid pBR322 generating pDV801 which served as the source of DNA in these studies (Fig. 1). A restriction map of the 1,102-base pair region is presented in Fig. 2.

To determine the nucleotide sequence of the 1,102-base pair region of Tn*9* bounded by the IS*1* sequences we used the rapid dideoxy chain termination technique developed by Sanger *et al.*[8]. Two methods were used to prepare the required single-stranded templates. One of these is exonuclease III digestion of double-stranded DNA[9]. This enzyme removes nucleotides from the 3′ ends of double-stranded DNA. Therefore, exonuclease III digestion of a linear double-stranded molecule will generate a single-stranded region which may be used as a template in the primed synthesis reaction (Fig. 3). A typical gel using templates prepared in this manner is shown in Fig. 4. The other method of obtaining single-stranded templates involves molecular cloning in the single-stranded filamentous bacteriophage M13 (ref. 10). Infection of susceptible strains (sex-factor carrying strains of *Escherichia coli* K12) with M13 results in the establishment of a carrier state in which the double-stranded replicative form (RF) of M13 is maintained at about 300 copies per cell, while mature phage, containing one of the complementary strands ((+) strand), is extruded into the medium[11,12]. It has recently been demonstrated that foreign DNA can be inserted into and stably maintained in the M13 RF (refs 10, 12–14). Since the limit to the size of the DNA packaged by filamentous phage appears to be very large, the inserted DNA can be packaged as single-stranded DNA covalently linked to the phage DNA. This single-stranded DNA can then be isolated and used as a template for the dideoxy sequencing method. By cloning the DNA in both

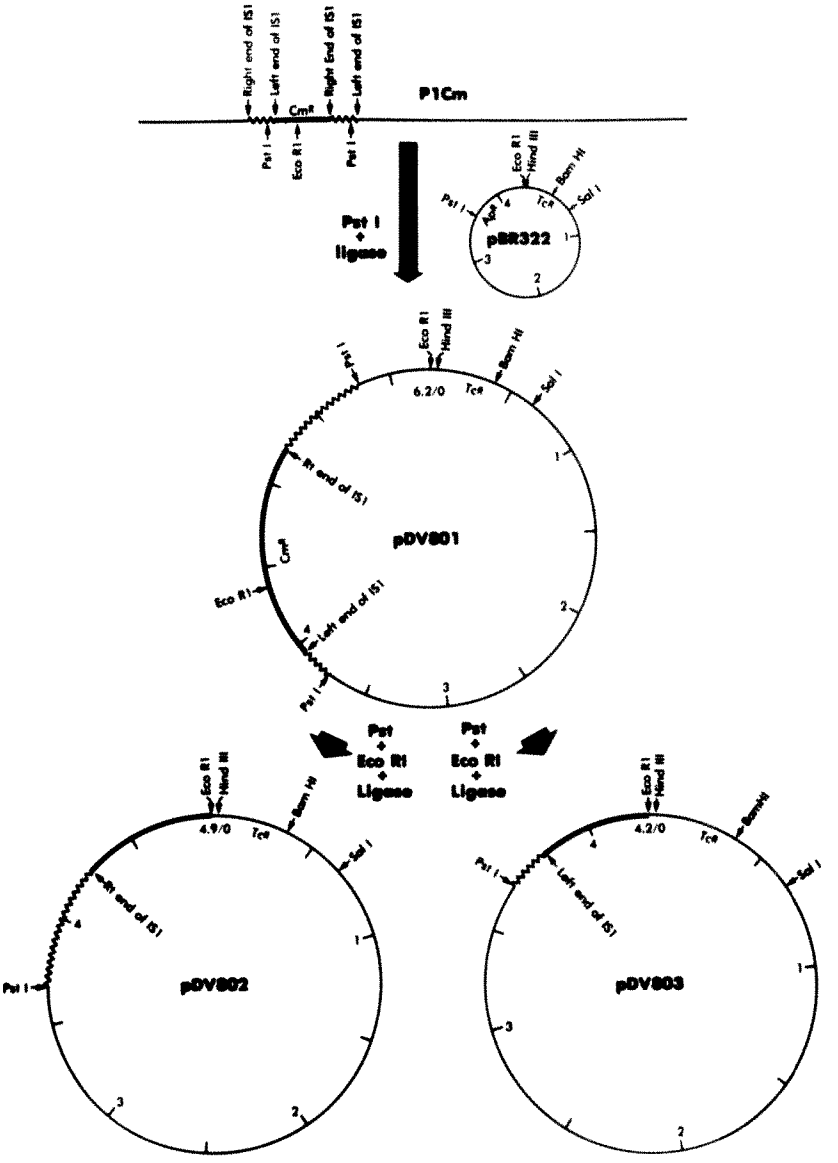

Fig. 1 Schematic representation of plasmid constructions. The derivation of pDV801 is shown and was previously described[36]. pDV802 and pDV803 were constructed by digestion of pDV801 with *Pst*I and *Eco*RI, treatment with T4 polynucleotide ligase, and transformation of *E. coli* C600 using published procedures[37]. The plasmids carried by several tetracycline-resistant, chloramphenicol sensitive strains were isolated and the fragments of Tn*9* they contained determined by digestion with *Eco*RI plus *Pst*I. pDV802 carries a 1,254 base-pair fragment containing the right end of IS*1* while pDV803 carries a 616 base-pair fragment containing the left end of IS*1*. Wavy lines indicate IS*1* sequences. The numbers within the circles refer to distances in kilobases.

orientations, either of the complementary strands can be isolated (Fig. 5*a*). An example of a sequencing gel using M13 templates is shown in Fig. 5*b*.

In initial sequencing experiments, the exonuclease III method was used to prepare templates. During this work the M13 method became available and was used in completing the sequence. For both methods, DNA fragments generated by restriction endonuclease digestion of the 1,870-base pair fragment of Tn*9* were used as primers (Fig. 2).

Using these techniques we have determined the nucleotide sequence of the 1,102-base pair region of Tn*9* bounded by the directly repeated IS*1* sequences (Fig. 6). In most regions both of the complementary strands were sequenced several times (Fig. 2). Amino acid sequence data of the CAT gene allowed further confirmation of the sequence as shown in Fig. 6 (ref. 6).

We have also sequenced approximately 200 base pairs within IS*1* including 40 base pairs at the right end and 70 at the left end. The sequence of these regions is identical to that determined by Ohtsubo and Ohtsubo[15] and Johnsrud[16].

Three unique restriction endonuclease cleavage sites are located within the CAT coding sequence. These are an *Eco*RI site (nucleotide 437), a *Bal*I site (nucleotide 704), and a *Pvu*II site (nucleotide 337) (Fig. 6). These sites are potentially useful for DNA cloning since insertion of DNA into these sites should lead to the loss of chloramphenicol resistance, thereby simplifying the screening of recombinants. Two cloning vehicles which carry the CAT gene, pBR325 and pACYC184, have been constructed and used as *Eco*RI vectors[17,18]. pBR325, however,

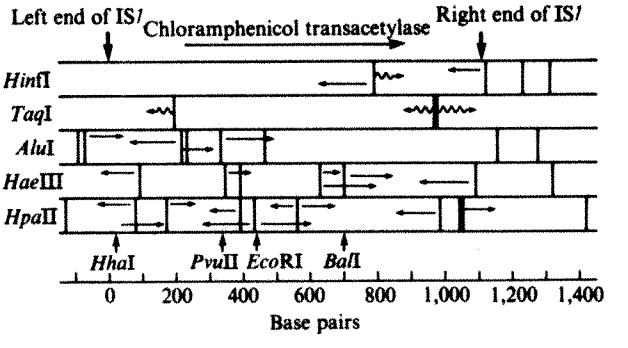

Fig. 2 Map of restriction endonuclease sites and sequencing strategy of the 1,102 base-pair region of Tn*9* contained between the IS*1* sequences. Positions of the endonuclease cleavage sites were determined using the technique described by Smith and Birnsteil[38] and by analysis of multiple digestion products as previously described[37]. Restriction endonucleases were obtained from New England Biolabs. Cleavage with restriction endonucleases *Hae*III, *Hpa*II, *Alu*I, *Taq*I and *Hha*I was carried out in H buffer which contains 6.6 mM Tris-HCl, *p*H 7.5, 6.6 mM $MgCl_2$, 6.6 mM NaCl, 5 mM dithiothreitol. Cleavage with restriction endonucleases *Pst*I, *Eco*RI and *Hin*fI was in H buffer plus 50 mM NaCl. All reactions were at 37 °C with the exception of *Taq*I which was at 60 °C. The position of the *Bal*I site is inferred from the nucleotide sequence. Vertical lines indicate cleavage sites for the endonucleases shown at the left. Arrows show the direction and extent of sequencing runs. Wavy arrows indicate sequencing runs performed using the Maxam and Gilbert technique[40]. The left and right ends of IS*1* are indicated.

has an additional *Pvu*II site as well as an additional *Bal*I site. These sites would have to be removed to make appropriate cloning vehicles for use with these restriction endonucleases.

Since the nucleotide sequences surrounding these sites are now known, they are also potentially useful for the formation of fused proteins. These fused proteins would then be under the control of the CAT promoter. It has recently been demonstrated that the CAT gene carried by pBR325 can be expressed in *Saccharomyces cerevisiae* (J. Cohen and R. Needleman, personal communication). Therefore, it would be feasible to test the expression of these fused proteins in yeast as well as in *E. coli*.

Analysis of the nucleotide sequence reveals an uninterrupted coding sequence for 219 amino acids beginning with the AUG initiator codon at nucleotide 224 and terminating with the nonsense codon UAA at nucleotide 881. This amino acid sequence is identical to that determined by Shaw *et al.* for the Type I CAT isolated from strains carrying plasmid JF66b (see the accompanying paper)[6].

Shine and Dalgarno[19] suggested that ribosome recognition of mRNA involves complementary base-pairing between the 3′ end of the 16S rRNA and the 5′ end of mRNA. Such complementarity has been confirmed by sequence analysis of a number of different genes[20–22]. Two such sequences are found preceding the initiation codon for the CAT gene. These are AGGAG (nucleotides 205–209) and TAAGGA (nucleotides 211–216). Based on its spacing from the AUG initiator codon, the sequence TAAGGA is most likely involved in ribosome recognition. However, it is possible that the AGGAG sequence might also have some role.

The sequence data in Fig. 6 show that the amino terminal codon of the CAT gene is located 224 nucleotides from the left end of IS*1*. Assuming that the CAT promoter is not in IS*1*, these 224 nucleotides encode the regulatory functions of the CAT gene. The level of expression of the CAT gene is regulated by the cyclic AMP receptor protein (CAP) and cyclic AMP[23,24]. The promoter regions of the lactose and galactose operons which are also regulated by CAP plus cyclic AMP contain a sequence, referred to as the CAP site, which precedes the start point of transcription (for reviews see refs 25, 26). This region presumably interacts with the CAP–cyclic AMP complex stimulating the initiation of transcription. Biochemical and genetic data have demonstrated that the CAP site in the *lac* promoter contains the sequence GTGAG----CACTC which is involved in binding the CAP–cyclic AMP complex[25]. Similar sequences are found in the promoter regions of the galactose and *araBAD* operons[27,28]. Inspection of the DNA sequence between the left end of IS*1* and the start of the CAT coding sequence reveals a similar sequence GTGA----TCAC (Fig. 6, nucleotides 29–43). By analogy with *lac*, *gal* and *araBAD* this region may be

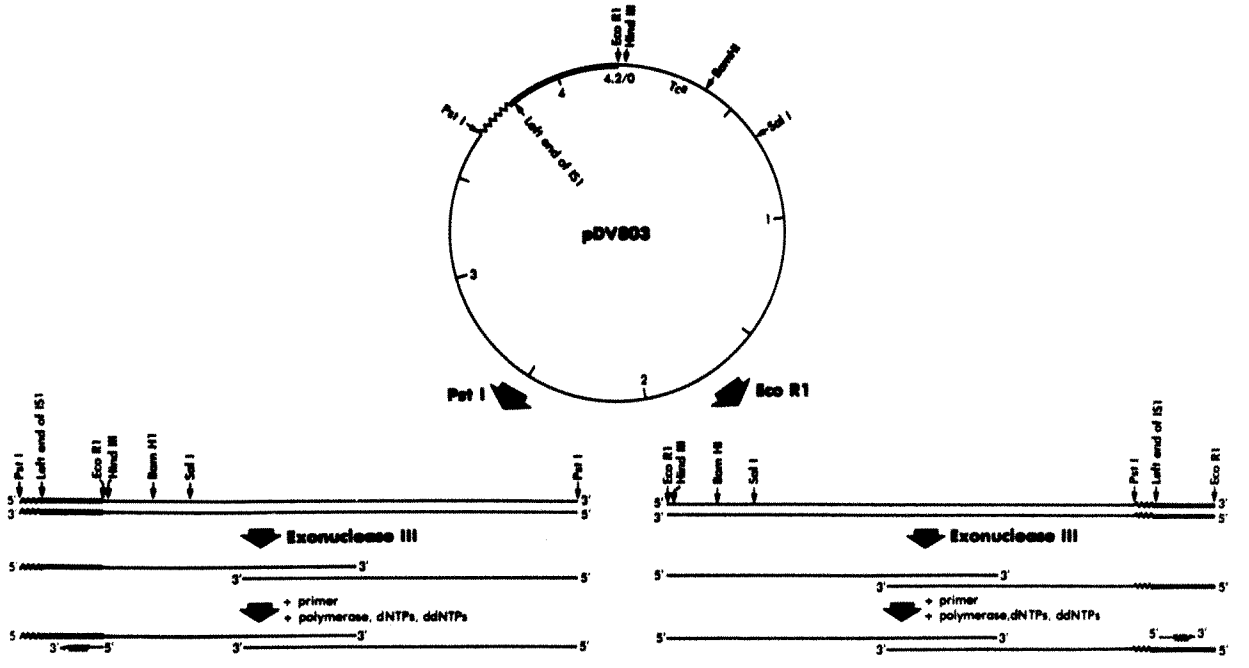

Fig. 3 Exonuclease III preparation of templates for the primed synthesis reactions. The most useful templates prepared by exonuclease III treatment were those containing the DNA to be sequenced at the end of the molecule. Therefore, plasmids to be used for preparing exonuclease III templates should contain unique restriction cleavage sites adjacent to the region to be sequenced. To prepare such plasmids we subcloned the fragments of Tn*9* generated by digestion of pDV801 with *Eco*RI plus *Pst*I. The two plasmids derived from this cloning, pDV802 and pDV803, have unique *Pst*I and *Eco*RI sites (Fig. 1). The use of one of these plasmids, pDV803, to prepare single-stranded templates is outlined above. Cleavage with *Pst*I followed by exonuclease III digestion exposes one strand of Tn*9* while cleavage with *Eco*RI followed by exonuclease III treatment exposes the opposite strand. By utilising both of these templates the sequence of the complementary strands could be determined. DNA prepared in this manner was suitable as a template using restriction endonuclease generated fragments less than 100 base pairs as primers. Larger fragments were not as useful since they must be cleaved with restriction endonucleases from the extended chains before gel electrophoresis. This cleavage step was necessary to obtain chains small enough (less than about 200 base pairs) to be resolved on the sequencing gel. However, cleavage of primers when using exonuclease III prepared templates led to artefactual bands in all lanes of the gel, probably due to residual double-stranded regions in the DNA template which could either be nick-translated or whose 3′OH ends could act as self-primers. In either case, restriction endonuclease digestion would release radioactively labelled chains. If these chains were of a size which would migrate within the resolving limits of the sequencing gel, they would appear as bands in all channels. Smith[9] found that this problem could be eliminated by more extensive treatment with exonuclease III. However, in our hands, longer exonuclease digestion led to degradation of the DNA and loss of template activity. Although such degradation of the single-stranded DNA might be due to the endonuclease III activity known to be associated with exonuclease III, this is unlikely since the endonuclease II activity has been shown to be specific for damaged DNA[39]. Another possibility is that some other nuclease was present in the preparation of exonuclease III used in these experiments. Exonuclease III can also be used for the preparation of primers (R. J. Roberts, personal communication). Double-stranded restriction endonuclease generated fragments were exhaustively digested with exonuclease III, and the products of this reaction used as primers with the M13 templates described in Fig. 5. Analysis of sequences determined by this technique demonstrated that the double-stranded fragment had been reduced to single-stranded primer of approximately 15 bases. If the double-stranded fragments treated with exonuclease III for use as primers are small (less than the resolving limits of the sequencing gel), sequences adjacent to the fragment can also be determined.

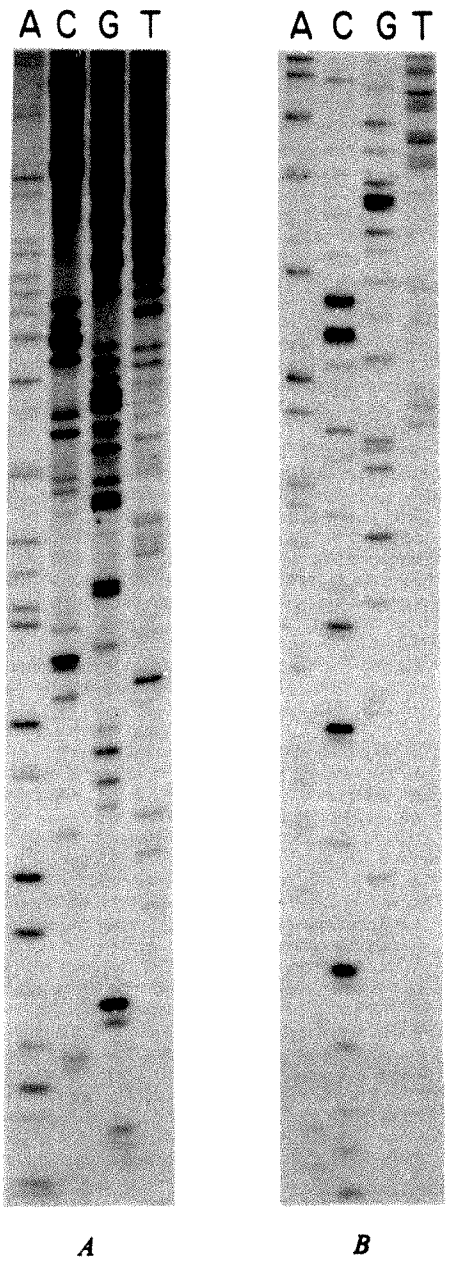

Fig. 4 Autoradiogram of a sequencing gel using exonuclease III treated templates and primers. Plasmid DNA was isolated as previously described and purified by isopycnic centrifugation in CsCl-ethidium bromide gradients[37]. The DNA was further purified by velocity sedimentation in a 5–20% neutral sucrose gradient containing 1 M NaCl, 0.1 M Tris-HCl, *p*H 7.0. 100–200 μg of DNA was layerd on a 5 ml gradient and centrifuged for 3.5 h at 40,000 r.p.m. in a SW50.1 rotor. Peak fractions containing the DNA were pooled and the DNA precipitated by the addition of 2.5 volumes of 95% ethanol, pelleted by centrifugation (40,000 r.p.m., 20 min), resuspended in distilled water and stored frozen at −20 °C. For exonuclease III treatment, 10 μg of DNA was digested with either *Pst*I or *Eco*RI (H buffer + 50 mM NaCl) in 25 μl followed by incubation for 10 min at 65 °C to inactivate the restriction endonucleases. The DNA was then dialysed for 2 h against 200 ml of exonuclease III buffer (50 mM Tris-HCl, *p*H 8.0, 1 mM $MgCl_2$, 1 mM dithiothreitol (DTT)). The volume was adjusted to 50 μl and 10 units of exonuclease III (New England Biolabs, 1 unit per μg DNA) was added. After incubation for 45 min at 37 °C, an additional 10 units of exonuclease III was added and incubation was continued for 30 min at 37 °C. Exonuclease III was inactivated by a 15 min incubation at 65 °C and the DNA was stored at −20 °C. For use as a template, 0.1 pmol of exonuclease III-treated DNA was mixed with 0.5 pmol of restriction fragment primer prepared as described below in a final volume of 10 μl containing H buffer. This mixture was then sealed in a glass capillary, boiled for 3 min and hybridised at 68 °C for 30 min. 2 μl of this mixture was used in each reaction as described below. Extension with *Pol*I (Klenow fragment, New England Biolabs) in the presence of deoxynucleotide triphosphates and dideoxynucleotide triphosphates was performed essentially as described by Sanger *et al.*[8]. Reactions were carried out in 1.5 × H buffer containing 0.5 μM [α-^{32}P]dATP (400 Ci mmol^{-1}, Amersham Radiochemicals) and nucleotides at the following concentrations:

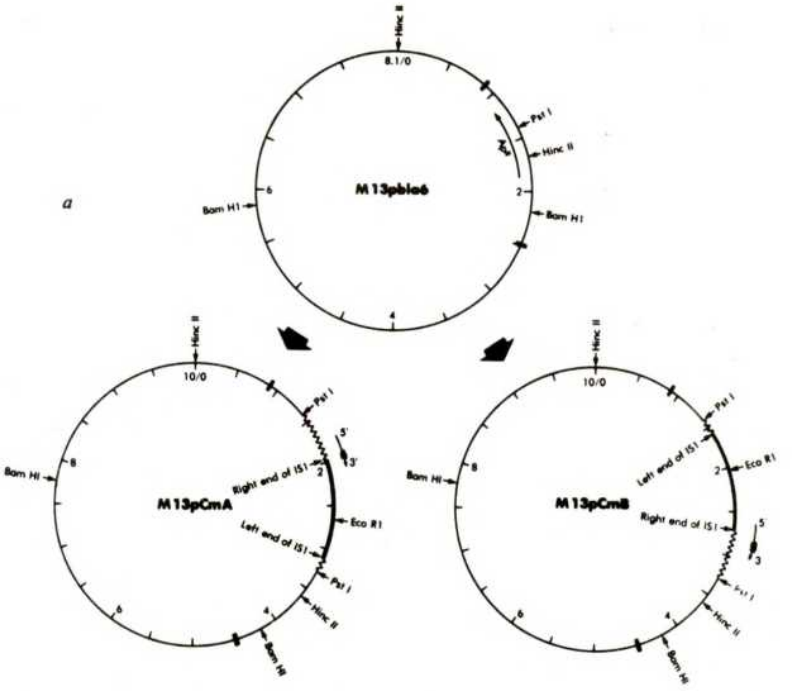
ddA: 35 μM dCTP; 35 μM dGTP; 35 μM dTTP; 50 μM ddATP
araC: 3.5 μM dCTP; 35 μM dGTP; 35 μM dTTP; 5000 μM araCTP
ddC: 3.5 μM dCTP; 35 μM dGTP; 35 μM dTTP; 200 μM ddCTP
ddG: 35 μM dCTP; 3.5 μM dGTP; 35 μM dTTP; 200 μM ddGTP
ddT: 35 μM cCTP; 35 μM dGTP; 3.5 μM dTTP; 200 μM ddTTP

All reactions were performed in glass capillaries in a final volume of 5 μl containing 0.2 units of DNA polymerase (Klenow fragment). After incubation for 15 min at room temperature, 1 μl of 0.5 mM dATP was added to each reaction and incubation was continued for 5 min at room temperature. If restriction endonuclease cleavage was necessary, 0.2 μl of restriction endonuclease was added to each reaction and incubated at 37 °C for 5 min. 10 μl of dye mix (90% deionised formamide, 0.25% bromphenol blue, 0.25% xylene xyanol) was added and the reactions were boiled for 3 min prior to gel electrophoresis. If restriction endonuclease cleavage was not necessary, the dye mix was added immediately following the dATP chase step. *Panel A*, pDV803 was prepared as a template by cleavage with *Pst*I followed by treatment with exonuclease III as described above. The primer was a 14-base pair DNA fragment isolated from a multiple digestion (*Hae*III + *Hpa*II + *Alu*I) of the 616-base pair fragment of Tn*9* (isolated from pDV803). The products of this reaction were fractionated on a 40 cm × 20 cm × 1.5 mm 12% polyacrylamide gel containing 25% glycerol in TB buffer. After electrophoresis, the gel was stained with ethidium bromide; individual bands were cut out and the DNA eluted from the acrylamide by soaking in 1.2 ml of buffer (0.3 M NaOAc, 0.1 M Tris-HCl, *p*H 8.0, 2.5 mM EDTA) for 16 h at 37 °C. The DNA fragments were then precipitated by addition of 2.5 volumes of ethanol, centrifuged in a SW50.1 for 30 min at 30,000 r.p.m., resuspended in distilled water and stored frozen at −20 °C. Primer–template hybridisation and chain elongation were as described above. There was no cleavage step with restriction endonuclease after extension with DNA polymerase (Klenow fragment). Sequence begins at nucleotide 73 and proceeds to the left (complement to the strand shown in Fig. 6). *Panel B*, 1.0 pmol of a 420-base pair DNA fragment generated by digestion with endonuclease *Hae*III was incubated in a volume of 15 μl containing 4 units of exonuclease III in 50 mM Tris-HCl, *p*H 8.0, 1 mM DTT, 1 mM $MgCl_2$ for 1 h at 37 °C. The mixture was then sealed in a capillary and boiled for 3 min. 5 μl of this mixture (0.33 pmol) was annealed with 0.1 pmol of M13pCmA DNA and used as a substrate for the primed synthesis reaction as described above. Electrophoresis in both panels was for 2 h at 35 W constant power on an 8% polyacrylamide–7 M urea gel (40 cm × 20 cm × 0.45 mm) as described by Sanger and Coulson[41]. The sequence begins at nucleotide 1,070 and proceeds to the left (complement to the strand shown in Fig. 6).



involved in the interaction with CAP–cyclic AMP complex. The CAP sites of the *lac*, *gal* and *araBAD* promoters are bounded by AT-rich sequences. Similarly, the putative CAP site in the CAT promoter is bounded by direct repeats of the AT-rich sequence GAATAAATA (Fig. 6, position 17–25 and position 50–58). Whether these sequences are also involved in the CAP–cyclic AMP interaction is not known.

Other features common to promoters are sites of the molecular interaction with RNA polymerase. Two common sites have been defined from mutational and sequence analysis of a number of different promoters. One of these is the heptanucleotide TATPuATPu (Pribnow box) which is centred approximately 10 nucleotides before the start point of transcription[29]. The other is the so-called −35 region which is centred approximately 32 nucleotides before the start point of transcription[30]. Although several such sequences are present in the CAT promoter, assignment of a specific role to these sequences awaits determination of the 5′ termini of the CAT mRNA(s).

The *ochre* codon at nucleotide 881–883, which is presumably the translational stop for the CAT gene, is immediately followed by the sequence TTTTTTTAA and preceded by a GC-rich region (13 of 14 base pairs). This region may represent the CAT mRNA termination site. This assumption is based by comparison with other genes in which similar sequences have been observed at the transcriptional termination site (for review, see ref. 31). However, the inverted repeat sequences found in these other instances (characteristic of ρ-dependent termination) which can potentially form stem-loop structures, are not found in the CAT DNA sequence.

Of the 1,102 base-pair region of Tn*9* bounded by the IS*1* sequences, at least nucleotides 28–883 are involved in the expression of CAT. An analysis of the sequence distal to the CAT translational stop signal reveals an uninterrupted coding sequence for 75 amino acids beginning with an AUG initiator codon at nucleotide 965 and extending 81 nucleotides into IS*1*. No other protein larger than 40 amino acids can be predicted from translation of all three reading frames of either strand of the 1,102 base-pair region.

Arber *et al.* have shown that Tn*9* carries fusidic acid resistance as well as chloramphenicol resistance[32]. Based on the sequencing data, fusidic acid resistance must be due to either

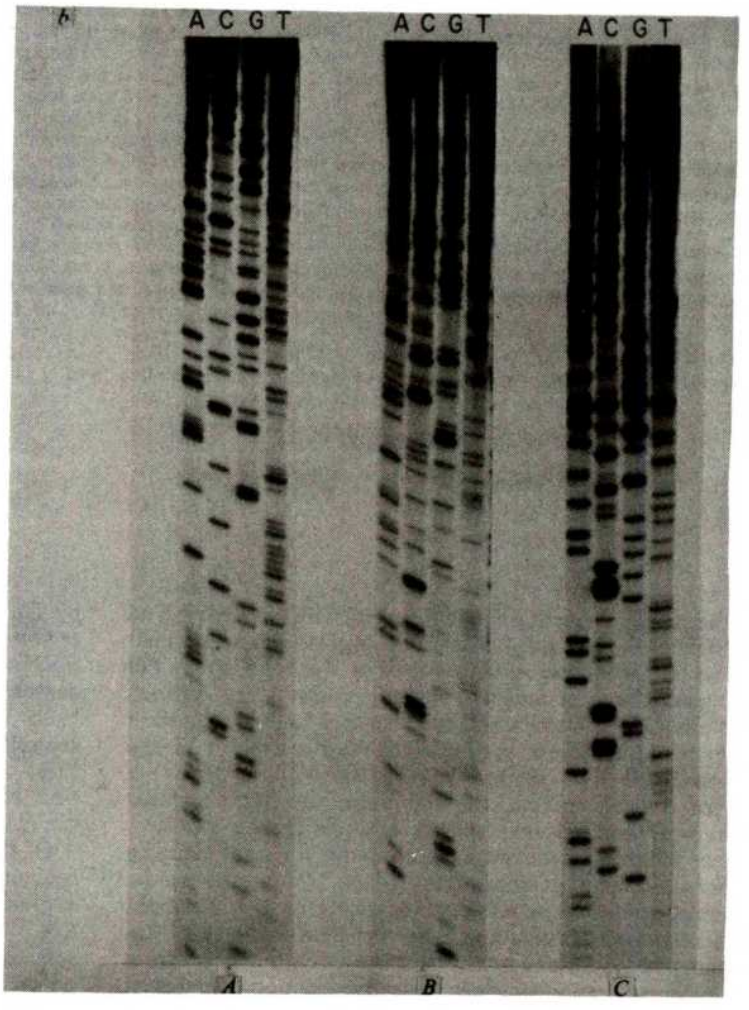


Fig. 5 *a*, Schematic representation of Tn*9* fragments cloned in M13pbla6. A derivative of M13 Tn3–15 was used as a cloning vehicle[13]. This phage, M13pbla6, contains the β-lactamase gene from Tn*3* inserted in the intercistronic region between genes II and IV of M13 (D. Ray and S. Hines, personal communication). Strains which harbour M13pbla6 are therefore ampicillin resistant. The single *Pst*I site in M13pbla6 was used to clone the 1,870 base-pair fragment of Tn*9* generated by digestion with *Pst*I. Since the *Pst*I site of M13 is within the β-lacatmase gene, insertion of the 1,870 base-pair fragment at this site resulted in phages which conferred the phenotype chloramphenicol resistance-ampicillin sensitivity on infected cells. RF DNA was isolated from infected cells with this phenotype as described below and analysed by restriction endonuclease digestion. Of 28 independent isolates screened, 26 carried the inserted fragment in one orientation (M13pCmA) and only two were in the other orientation (M13pCmB). Barnes[14] also noted an orientation effect in cloning the *His* operon DNA into M13. In that instance a slower growth rate and a lower yield of phage was observed when DNA was inserted in one particular orientation. Phage DNA was isolated from M13pCmA and M13pCmB and used as templates with primers prepared from restriction endonuclease generated fragments of pDV801, pDV802, and pDV803. Since the template is completely single-stranded, no template related problems were encountered when the primers were recleaved from the extended chains with restriction endonucleases. However, successful cleavage with restriction endonucleases was dependent upon the particular lot of endonuclease used. M13pbla6 was purified from infected cells as described by Messing[10]. 0.5 μg of this DNA was cleaved with *Pst*I and mixed with 0.35 μg of the 1,870 base-pair DNA fragment of Tn*9* (purified from pDV801). Ligation with T4 polynucleotide ligase was performed in a final volume of 50 μl of H buffer (see legend to Fig. 2) plus 0.4 mm ATP for 16 h at 5 °C. 0.5 μl of this mixture was used to transfect 0.1 ml of Ca^{2+} treated *E. coli* K802F'lac (ref. 10). The transfected cells were mixed with 0.2 ml of uninfected cells (4×10^7 cells) and overlayed on YT plates. Infected cells from individual plaques were tested for chloramphenicol resistance. Small cultures were grown from chloramphenicol-resistant infected cells and RF DNA was isolated as previously described for plasmid screens[37]. The RF DNA was digested with *Pst*I to determine whether the Tn*9* fragment was present, and with *Eco*RI plus *Hin*dII to determine the orientation of the inserted fragment. The two orientations (M13pCmA and M13pCmB) are shown schematically. The numbers indicate the size of the phage DNA in kilobases. To prepare M13pCmA and M13pCmB single-stranded DNA, the supernatant from a litre culture of infected cells grown in YT medium was adjusted to 0.5 M NaCl and the phage precipitated by the addition of polyethylene glycol to a final concentration of 4%. Precipitated phage were collected by centrifugation and resuspended in 10 mM Tris-HCl, *p*H 7.4, 10 mM $MgCl_2$. After a low speed spin (10,000 r.p.m. for 10 min) to remove cellular debris, the phage was lysed by heating in 0.5% SDS, 50 mM EDTA for 10 min at 65 °C. The phage DNA was extracted with phenol followed by extraction with phenol–chloroform and precipitated with 2.5 volumes of 95% ethanol. The DNA was further purified by centrifugation for 3 h in a 5–20% neutral sucrose gradient as described in the legend to Fig. 4. For use as a template, 0.1 pmol of DNA was used and the reactions carried out as described in the Fig. 4 legend. The arrows indicate the direction of chain extension after annealing with primers. *Fig. 5b*, Autoradiogram of a sequencing gel utilising M13pCmA or M13pCmB templates. pDV802 or pDV803 (6 pmol) were cleaved with *Pst*I plus *Eco*RI in H buffer containing 50 mM NaCl. The DNA was precipitated with 2.5 vol ethanol and resuspended in 30 μl of distilled water. 2.5 μl (0.5 pmol) of this DNA was mixed with 0.1 pmol of template (M13pCmA or M13pCmB) prepared as described above. After boiling for 3 min in a sealed capillary, annealing and chain elongation were carried out as described in the Fig. 4 legend. After incubation with *Pol*I and a 5 min chase with 1 μl of 0.5 mm dATP, 0.2 μl (10 units) of *Eco*RI (panels *A* and *B*) was added and the incubation continued at 37 °C for 5 min before addition of the dye mix. Electrophoresis on a 8% polyacrylamide–7 M urea gel was as described in the legend to Fig. 4. *Panel A*, M13pCmA template, pDV802 cleaved with endonucleases *Pst*I plus *Eco*RI as primer. Sequence begins at nucleotide 412 and proceeds to left (complement to strand shown, Fig. 6). *Panel B*, M13pCmB template, pDV803 cleaved with endonuclease *Pst*I plus *Eco*RI as primer. Sequence begins at nucleotide 470 and proceeds to the right (strand shown in Fig. 6). *Panel C*, M13pCmB template, 105-base pair *Alu*I generated DNA fragment primer. After extension and chase, 0.2 μl *Pvu*II was added to release the extended chains. Reaction conditions and primer purification were as described in the legend to Fig. 4. Sequence begins at nucleotide 373 and proceeds to the right (strand shown in Fig. 6).

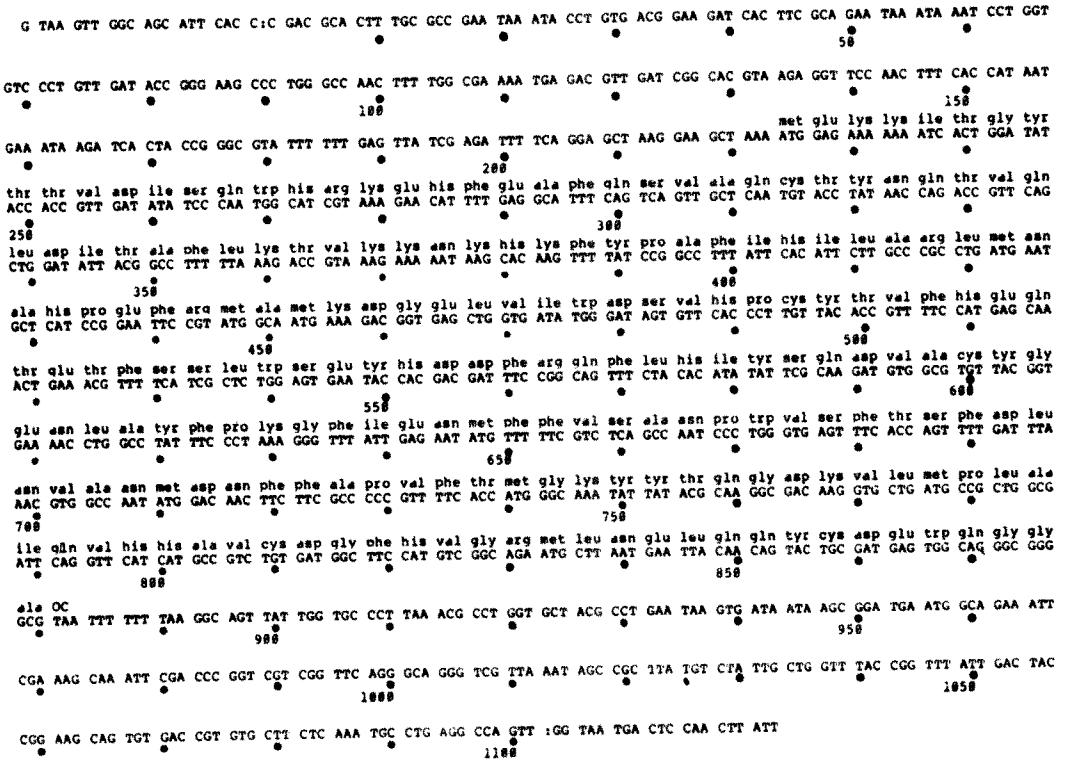

Fig. 6 Nucleotide sequence of the 1,102 base-pair region of Tn*9* between the direct repeats of IS*1*. The amino acid sequence of chloramphenicol acetyl transferase predicted from the nucleotide sequence is indicated above the respective codons. Numbering of nucleotides beginning at the left end of IS*1* (designation of Ohtsubo and Ohtsubo, ref. 15) is as shown. The junctions with IS*1* are indicated by a colon (:). 20 nucleotides from both the left and right ends of the IS*1* sequences present in Tn*9* are also shown.

one of the small putative peptides coded for by this region or by the CAT gene itself. If the CAT gene is involved in fusidic acid resistance, the biochemical basis for such an effect is obscure[33].

The complete nucleotide sequence of a transposon encoding a heat stable toxin from *E. coli* (Tn*1681*) has recently been completed (M. So, F. Heffron and B. McCarthy, personal communication). Although the IS*1* sequences are directly repeated in Tn*9*, this arrangement does not seem to be required for transposition as Tn*1681* is bounded by inverted repeats of IS*1* (ref. 34). A comparison of the internal sequences of Tn*9* and Tn*1681* bounded by the IS*1* sequences reveals no significant homology. Furthermore, there is no apparent relationship between the sequence at both internal IS*1* junctions in either Tn*9* or Tn*1681*. Although the putative protein described above could be involved in transposition, we feel this is unlikely since IS*1* itself is transposable and, in the case of Tn*1681*, no protein initiating within the internal sequences of Tn*1681* and extending into IS*1* can be predicted from the nucleotide sequences. Taken together these data suggest that in transposons bounded by insertion sequences, like Tn*9* and Tn*1681*, the information required for transposition resides within the flanking insertion sequences. In contrast, the internal regions of transposons like Tn*3* (encoding ampicillin resistance), which are not flanked by insertion sequences encode functions necessary for their own transposition[35]. In either case, a contribution of host functions to the transposition process is not ruled out.

This work was performed during a sabbatical at the University of California, San Francisco, in the Howard Hughes Medical Institute, Department of Biochemistry and Biophysics. We are grateful to Herb Boyer for laboratory facilities and for encouragement. We thank G. Nigel Godson for instruction in the dideoxy sequencing techniques, W. V. Shaw for providing amino acid sequence data prior to publication, Keith Backman for helpful discussions, Dan Ray for M13pbla6, Joachim Messing for providing protocols for the M13 method, Hugo Martinez for help with computer analysis and Pat Clausen for typing the manuscript. This work was supported in part by NIH grants GM20160 and AI11489. D.V. is the recipient of NIH Career Development Award GM00090.

Naturally occurring isolates of chloramphenicol-resistant bacteria commonly synthesise chloramphenicol acetyltransferase (EC 2.3.28; CAT) in amounts which are sufficient to account for the resistance phenotype and often harbour plasmids which carry the structural gene for CAT[1,2]. The finding of CAT in such diverse prokaryotes as *Proteus mirabilis*, *Agrobacterium tumefaciens*, *Streptomyces* sp., and a soil *Flavobacterium* has led to speculation concerning the origin and evolution of the more commonly observed CAT variants specified by plasmids in clinically important bacteria[2]. To provide a more solid basis for studying the evolution and spread of CAT within prokaryotes we chose to determine the complete amino acid sequence of a type I variant of CAT, the variant known to be associated with most F-like plasmids conferring chloramphenicol resistance. The sequence has been determined by combining the results obtained from manual and automated sequential degradation with those obtained by mass spectrometry of peptides generated by enzymatic digestion. The directly determined primary structure is identical with that predicted by the DNA sequence analysis[3] of the chloramphenicol resistance transponson Tn*9* known to specify a type I variant of chloramphenicol acetyltransferase.

CAT catalyses the acetylation of chloramphenicol to yield as the inital product 3-acetoxychloramphenicol which is devoid of significant antibiotic activity[4]:

chloramphenicol + acetyl-S-CoA → 3-acetoxychloramphenicol + HS-CoA

The plasmid-borne chloramphenicol resistance conferred by CAT in *Escherichia coli* and other related Gram-negative bacteria is a constitutive property of such strains whereas staphylococci synthesise CAT only after exposure to the antibiotic or closely related compounds including a gratuitous inducer which neither serves as a substrate for CAT nor is an antibiotic[5]. Three reasonably well defined and divergent types of CAT have been shown to be mediated by plasmids in Gram-negative bacteria whereas staphylococcal plasmids appear to specify at least four closely related variants[6,7].

All CAT variants studied to date appear to exist in solution as tetramers of four identical subunits[8]. The CAT monomers of all variants possess molecular weights in the range 22,000–24,000 by SDS-polyacrylamide gel electrophoresis. In the light of the calculated molecular weight for the complete 219 amino acid primary structure of the enzyme described below, it seems likely that the expected monomeric molecular weights of most if not all CAT variants will need to be revised upwards.

The yield of pure protein was maximised without recourse to recombinant technology by taking advantage of several intrinsic advantages of the system. High level chloramphenicol resistance mutants can be isolated by selection for other plasmid-linked drug resistance markers, yielding high copy number plasmids[9]. Furthermore, the expression of CAT is known to be subject to cyclic AMP-mediated catabolite repression and, hence, growth of bacterial cells on glycerol rather than glucose can lead to up to fivefold increases in yield of CAT[10]. Finally, the development of a reproducible high capacity affinity chromatographic method for the purification of CAT has given almost quantitative recovery of electrophoretically homogeneous material in a single purification step[11]. One gramme of pure CAT specified by plasmid JR66b was used for most of the studies described. Supplementary information has been provided by structural studies on smaller amounts of a closely related type I variant specified by plasmid R429 (ref. 12).

The initial approach to determining the complete covalent structure of CAT took account of several preliminary observations. The protein was known to contain not less than seven methionines, one of which was N-termional and unblocked. Although tryptic digests of the reduced and carboxymethylated protein yielded useful peptide maps, there were regions of structure not likely to be represented in soluble peptides. By contrast and as expected, digests of CAT with chymotrypsin and elastase went smoothly. The overall plan was therefore as follows: (1) determine the N-terminal amino acid sequence by automated Edman degradation; (2) prepare and sequence fragments isolated after cleavage at methionines with cynaogen bromide, using both automated Edman degradation and enzymic sub-digestion followed by manual 'dansyl' Edman methods; and (3) explore the use of mass spectrometry (MS) to determine the amino acid sequence of fragments generated by chymotrypsin, elastase and subtilisin. A particular advantage of the use of mass spectrometry was not only the relative speed with which the sequence of many small (three to nine residue peptides can be determined but also the attraction of 'mixture analysis' to get sequence information from column or paper fractions containing several peptides[13]. In addition to these three main approaches we also took advantage of the results obtained by dansyl Edman and automated sequence analysis of certain tryptic peptides and results of manual sequencing of chymotryptic or elastase peptides to extend the information from the mass spectrometry results. The techniques used have been described in detail elsewhere[13–18].

The complete amino acid sequence of CAT is shown in Fig. 1. The data have been presented in a manner which, although unconventional, may help to show (1) the amount of redundant information insuring accuracy throughout most of the structure, (2) the regions where overlaps or redundancy are limited, and (3) the very large fraction (182 residues or 83%) of the structure which was determined by mass spectrometry. In addition, it may be useful to note that the heavy dark line above the sequence indicates the structure also determined unambiguously for the type I CAT specified by plasmid R429. The sole differences detected between these two proteins thus far have been the tighter binding to affinity resins of the enzyme encoded by R429 and the amino acid difference at residue 162, the substitution of Ala for Asn.

Several regions of the structure were particularly troublesome. The N-terminal sequence analysis by Edman degradation using both liquid ('spinning cup') and solid phase techniques gave a sharp drop in signals after Gln 15, probably due to cyclisation and blockage. The crucial chymotryptic peptide spanning the region from His 17 to Phe 25 was in low yield and contained Arg. Although sequenced by the dansyl-Edman approach, it was only correctly placed in the sequence when it became obvious that it was contained in the C-terminal part of the elastase fragment spanning Asp 12 to Ser 27. The 'expected' L4 tryptic peptide (Glu 20 at N-terminus) was never isolated and CB-2 was a low-yield 66-residue fragment which was known only by its analysis, and by N- and C-terminal sequences.

A second region of the structure which gave rise to difficulties until the late stages of the project was the two amino acid overlap at 162–163, determined both by dansyl-Edman and mass spectrometry on the elastase fragment Asn 162 to Val 170.

Our search for ambiguities and errors in overlapping peptides in the regions mentioned was prompted by access to the DNA sequence data of the Basle group[26] for the region of their transposon which corresponded to the first 142 amino acids of

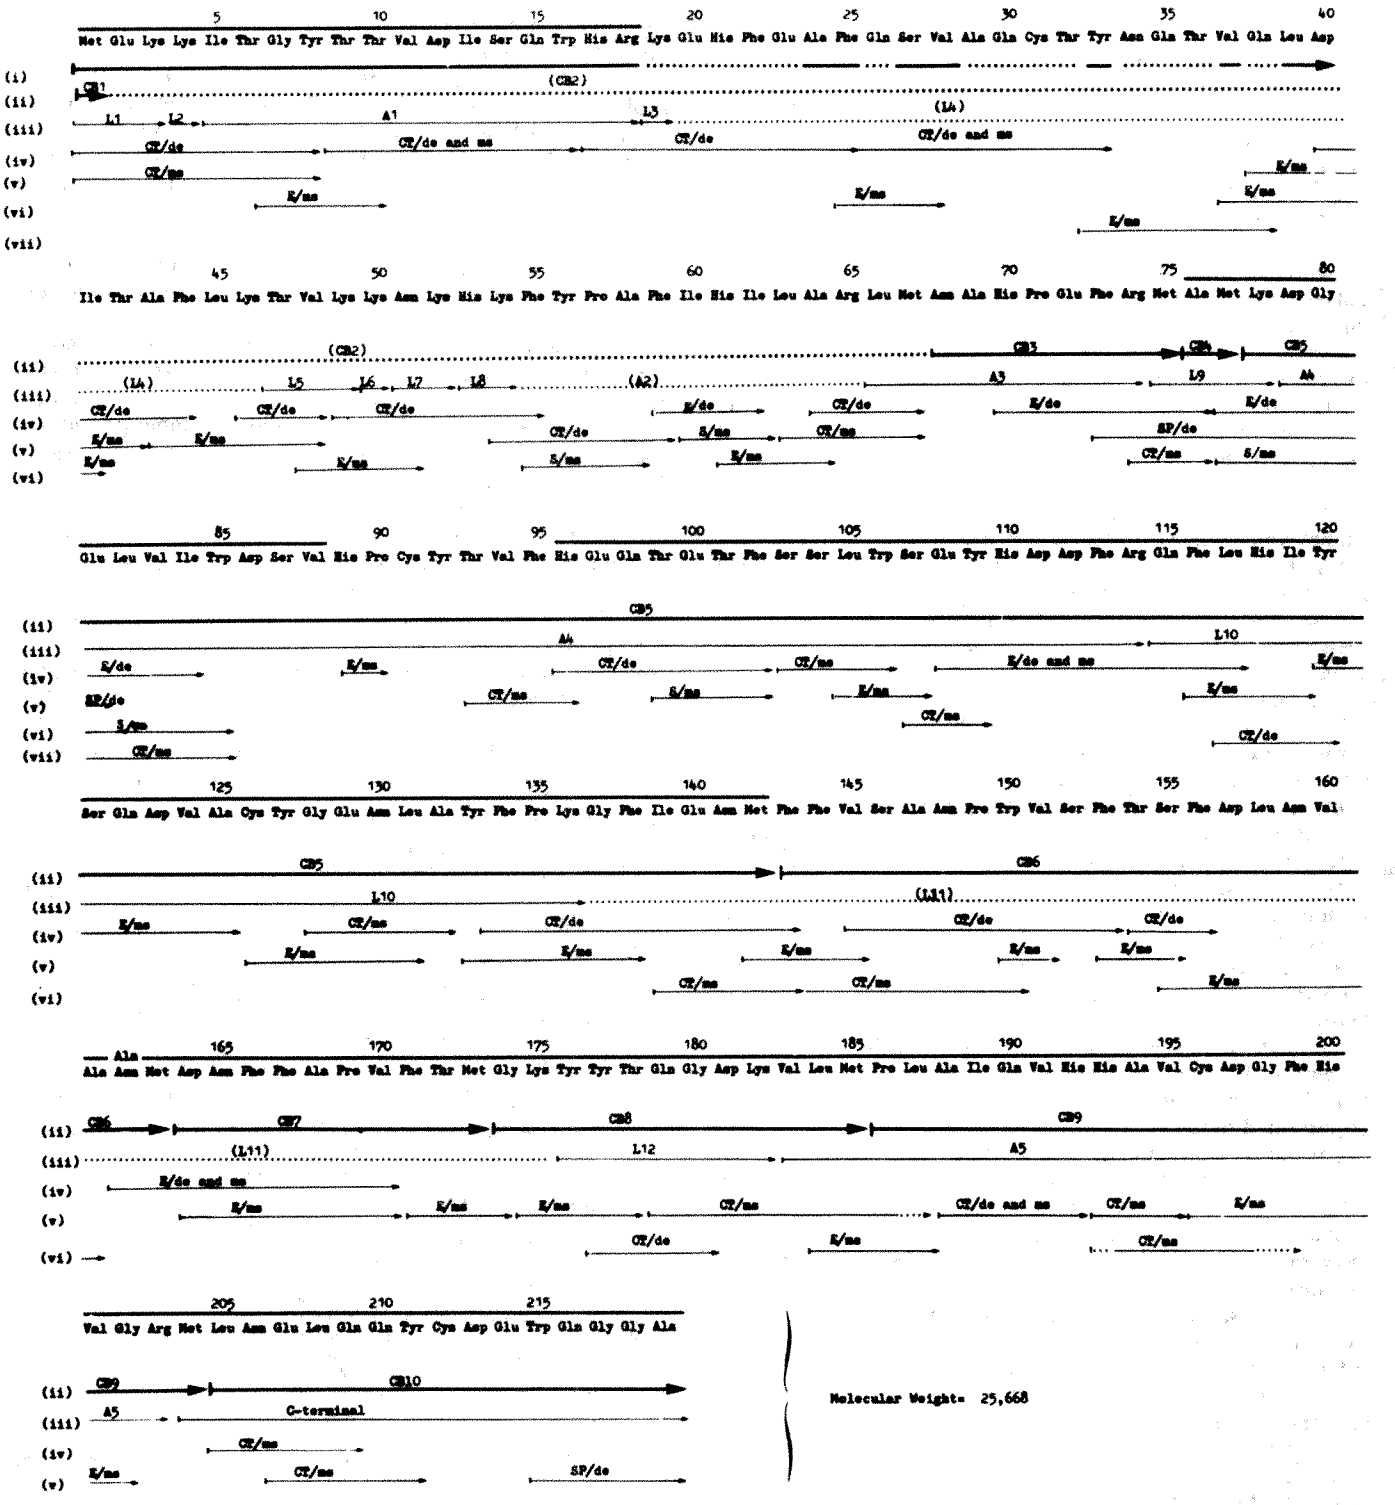

Fig. 1 Amino acid sequence of chloramphenicol acetyltransferase specified by plasmid JR66b. Line (i) indicates the results of automated Edman degradation to residue 40. Dotted underlining indicates ambiguous results or no signal on thin layer, gas chromatography, or back hydrolysis of PTH amino acids. Line (ii) shows cyanogen bromide fragments which were sequenced either by automated Edman degradation or subdigestion with proteases to yield smaller peptides which were sequenced by the dansyl-Edman technique. Line (iii) shows the tryptic fragments and lines (iv–vii) indicate peptides generated by digestion of the protein with chymotrypsin (CT), subtilisin (S), elastase (E), or staphylococcal protease (SP) and sequenced by mass spectrometry (ms) or the dansyl-Edman method (de). All cyanogen bromide digests were performed on *S*-cysteinyl[^{14}C]carboxymethylated protein and the fragments were purified by a combination of gel filtration in 20% formic acid or 6M guanidine hydrochloride and DEAE-cellulose chromatography. One chymotryptic digest was performed on performic acid oxidised protein and one on enzyme which had been *S*-aminoethylated with ethylene imine. The elastase and staphylococcal protease digests were performed on ^{14}C-carboxymethylated protein. Peptides from chymotrypsin and elastase digests were purified by Dowex 50 ion-exchange chromatography using a pyridine-acetate eluant or by DEAE-cellulose chromatography with a linear gradient of ammonium bicarbonate. High voltage paper electrophoresis and chromatography were used for purification of pooled column fractions after removal of salt by lyophilisation or gel filtration on Sephadex G-10. The numbering system for tryptic peptides takes into account hypothetical peptides which were never isolated (dotted lines). The same convention was used for cyanogen bromide fragments. The heavy line above the amino acid sequence indicates the extent of sequence analysis performed on the CAT specified by plasmid R429, all of which is identical with that of plasmid JR66b save for Asn 162 which is Ala in the R429 variant of CAT.

CAT. Re-alignment of the peptides in the regions noted above yielded the primary structure shown in Fig. 1.

Although the data summarised in Fig. 1 are presented in such a way as to summarise the evidence from which the structure has been deduced, we have drawn attention to regions which may be of functional importance. In the native enzyme the chloramphenicol binding site seems likely to include portions of the structure near Cys 31 as well as the segment from His 192 to Cys 196 (ref. 19). Studies done on a staphylococcal variant of CAT, which shows a high degree of conservation in the latter region but less than 50% homology elsewhere, have implicated His 192 on the basis of experiments with alkylation by iodoacetamide and diethylpyrocarbonate inhibition[17]. The protection afforded by chloramphenicol to inhibition at all three residues is not seen with acetyl-S-CoA. In the fully folded native structure, the coenzyme-binding domain may exist within the N-terminal one-third of the polypeptide. The evidence on this point is both circumstantial and indirect; the truth will be known with certainty on the completion of high resolution X-ray diffraction studies which are in progress[20]. However, we note that there is a potential adenine nucleotide binding site in the N-terminal one-third of the polypeptide where application of the secondary structure parameters of Chou and Fasman[10] yields a desired domain consisting of alternating β structure and α-helix[22].

The matter of the points of contact between subunits of the CAT tetramer has recently been approached in the light of earlier studies on the ease with which very stable hybrid CAT tetramers can be generated *in vivo* and *in vitro*[12]. It seemed likely that salt bridges between monomers might be involved and that a search for 'buried' lysine residues might reveal one or more which, especially if found consistently among CAT variants, might be prime candidates for sites of contact between subunit interfaces. The strategy used was an extension of that described previously[23] and involved treatment of the native tetramer with nonradioactive methyl acetimidate followed by removal of the reagent, unfolding of the protein in guanidine hydrochloride and treatment with ^{14}C-labelled methylacetimidate to label any lysine residue previously shielded from solvent and unlabeled reagent. A unique amino group was modified by the radioactive imidoester, that of Lys 136 (L.C. P., unpublished data).

The amino acid sequences of most proteins—in the absence of further information on secondary or tertiary structures or collateral data on related proteins—are not particularly provocative, and the structure for CAT is no exception. Although much of the primary structures of two other plasmid coded CAT variants are known (*E. coli* type III and *Staphylococcus aureus* type C), an assessment of homology would be premature, apart from that which has already been made concerning the putative chloramphenicol binding site. Similarly, X-ray diffraction studies have not yet proceeded to a stage where useful inferences may be drawn.

The completion of the nucleotide sequence of Tn*9* by Alton and Vapnek[3] and by the Basle group[26] and the rapid progress made by other groups on analogous or homologous chloramphenicol resistance transposons have reinforced the points made by Sutcliffe that DNA sequence analysis offers compelling advantages in terms of time and resources as compared with protein sequencing[24]. On the other hand, the availability of limited amino acid sequence data on a structural gene of interest may be of considerable assistance as a guide to ambiguities in reading frame and is essential for anticipating post-translational modifications[25]. The evidence presented in this communication, that of the companion paper[3] and that of Marcoli *et al.*[26] indicate that in the case of the type I variant of CAT the results of the two approaches give identical results. Further studies on the CAT 'family' of proteins are now likely to proceed more rapidly as nucleotide sequence analysis replaces amino acid sequencing as the primary tool for generating primary structures for evolutionary studies and for the interpretation of electron density maps. However, we wish to stress the continued importance and necessity of protein chemistry for studies of catalytic function, subunit interactions, and ligand binding.

This work was initiated at the MRC Laboratory of Molecular Biology, Cambridge where W.V.S. and B.D.B. were visiting scientists. Much of the mass spectrometry work was done in the University Chemical Laboratory, Cambridge. We are grateful to both institutions for assistance and support. John Bridgen and John Walker were especially helpful with automated N-terminal sequence analysis. Subsequent studies were supported by the MRC in the form of a project grant (Leicester) and a programme grant (Imperial College). We thank F. Bolivar for base sequence data for the regions flanking the *Eco*RI site (Glu 72/Phe 73), information which first alerted us to an overlap error. We are particularly grateful to T. Bickle, S. Iida and R. Marcoli for early discussions of their proposed structure for the transposon derived from plasmid NR1, and we thank N. K. Alton and D. Vapnek for sharing their data before submission for publication.

Note added in proof: The primary structure of a transposable element smaller and analogous to that specifying the type I variant of CAT has now been determined[26]. Knowledge of the amino acid sequence of CAT and the nucleotide sequence of Tn*9* is likely to be particularly useful in the light of recent independent experiments by two groups which show that the gene product of Tn*9* is expressed well in yeast (*Saccharomyces cerevisiae*) when the chloramphenicol resistance determinant is part of a cointegrate composed of the yeast 2-μm plasmid and an *E. coli* vector (J. D. Cohen, R. Eccleshall, R. D. Needleman, H. Federoff, B. A. Buchferer and J. Marmur; and C. Lichtenstein and C. Scazzocchio; personal communications to W.V.S.).

E. coli ribosomal RNA contains sequences homologous to insertion sequences IS*1* and IS*2*

Perry Nisen & Lucille Shapiro

Department of Molecular Biology, Division of Biological Sciences, Albert Einstein College of Medicine, Bronx, New York 10461

The insertion sequence (IS) elements, IS*1* and IS*2*, present in multiple copies in the *Escherichia coli* chromosome[1–3], are transposable genetic elements of known nucleotide sequence[4,5]. These elements can modulate gene expression[6–7], but it is not known whether they normally function in genetic control. To

0028–0836/79/510872—03$01.00

© 1979 Macmillan Journals Ltd

determine whether IS elements could exert control through specific RNA transcripts, we hybridised λNNC$_{1857}$r14 (carrying IS*1*) and pBR322 (carrying a portion of IS*2*) to Northern blots[8] of *E. coli* RNA. Regions of homology between the IS elements and ribosomal RNA were observed. Computer analysis of reported nucleotide sequences detected large segments of homology between the IS elements and both 23S and 16S rRNA. Additional homologous sequences in ΦX174 and a leader region of a ribosomal protein gene cluster were also detected. The homologous sequence between IS*2* and 16S rRNA is the same sequence in ΦX174 DNA which codes for the ends of the *E* and *D* gene and the start of *J*. The partial IS sequences may represent silent evolutionary remnants or they could modulate the expression of genes carrying these sequences.

IS elements are specific segments of DNA which can undergo *rec*A-independent translocation between DNA sequences with no apparent homology. These elements can modulate gene expression, cause polar mutations when integrated into proximal regions of operons, and act as vehicles for chromosomal rearrangements[6,7]. They inactivate genes into which they insert, and reactivate them on precise excision. Two insertion sequence elements, IS*1* and IS*2*, which are present in multiple copies in the *E. coli* chromosome[1-3], have been entirely sequenced[4,5]. IS*1* contains several translation stop signals in all three reading frames and causes polar mutations when inserted in either orientation. Integration of IS*2* in one orientation can cause initiation of transcription of a proximal gene presumably because the IS sequence contains a promoter[10]. Integration of IS*2* in the opposite orientation causes transcription termination, possibly due to the presence of a *rho*-sensitive transcription termination signal[11]. IS*2* also contains several translational stop signals in all three reading frames[5].

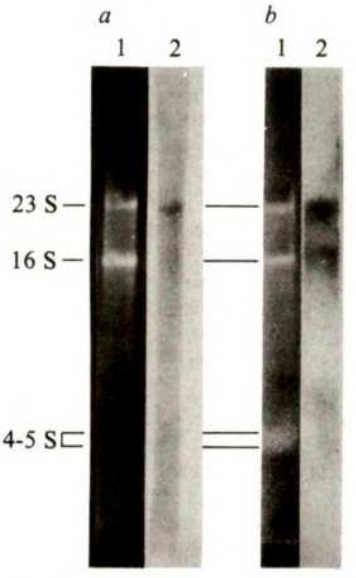

Fig. 1 Hybridisation of IS*1* and IS*2* to *E. coli* RNA. Whole cell RNA from an RNase$^-$ strain of *E. coli* K12 (Miles) was treated for 30 min at 37°C with 10 μg ml^{-1} of RNase-free DNase (Worthington) and then inactivated by heating to 65°C for 3 min. The RNA was then separated into its component size classes by 2% agarose gel electrophoresis in 20 mM phosphate buffer, *p*H 7.5. Ethidium bromide visualisation of two separate experiments are seen in *a*1 and *b*1. The RNA in the gels was blotted and bound to treated filter paper as described elsewhere[4]. Wild-type λ and λNNC$_{1857}$r14 (IS*1*) DNA obtained from purified phage particles[5], and purified plasmid pBR322 and pBR322 (IS*2*) DNA (described in ref. 9) were nick-translated by the method of Rigby *et al.*[20] using ^{32}P-dCTP (>300 Ci mmol^{-1}, NEN). These probes were hybridised to the above RNA containing filters as described[9] with the following exceptions: tRNA was used as cold carrier, and the filter paper was washed after hybridisation four times in hybridisation buffer at 37°C for 30 min, then four more times in 0.2 × SSC, 0.1% SDS at 37°C for 30 min. Wild-type λ DNA and pBR322 (without the IS*2* insert) did not hybridise to the filters. Autoradiograms of hybridisation of λNNC$_{1857}$r14 (IS*1*) and pBR322 (IS*2*) are seen in 1*b* and 2*b*, respectively. The predominant 23S, 16S and 4–5S rRNA size components are indicated.

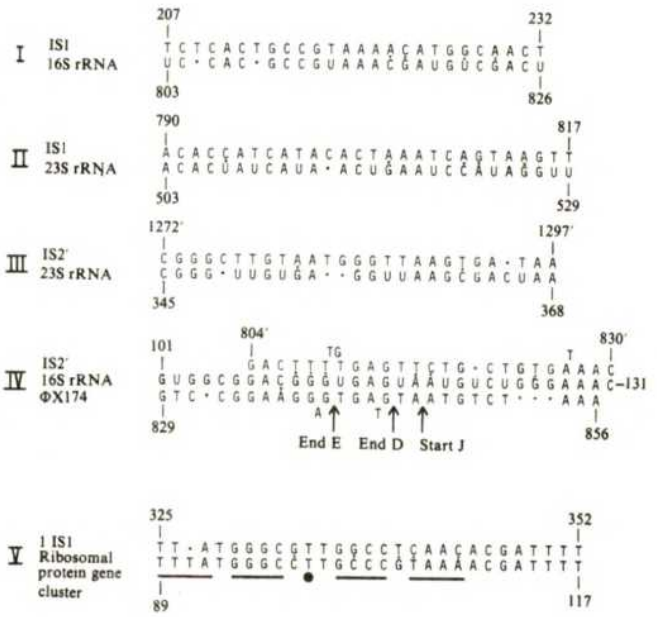

Fig. 2 Nucleotide sequence homologies detected by computer analysis. The computer program described by Korn and coworkers[13], as modified by Friefeld and Brutlag, was used to compare the nucleotide sequences of IS*1* (ref. 4) and IS*2* (ref. 5) to a portion of 23S rRNA, 16S rRNA[12], ΦX174 DNA[17], and a 3,000-base pair ribosomal protein gene cluster[18]. The numbers correspond to the coordinates from the published sequence. Primes correspond to the complementary strand of the reported sequence in inverted order. Dots indicate mismatches. The sequences shown are all considered statistically significant by the criteria and calculations defined by Brutlag.

There has been speculation concerning the role of IS elements in gene expression and evolution[6,7], but it is not clear whether these elements normally function in genetic control. Further, it is not known whether these elements act only at the DNA level (that is, promoter sequences, sequences inducing polarity), or can control gene expression at the post-transcriptional level. If portions of the IS elements exert their function through specific transcripts, then regions of homology between the IS elements and *E. coli* RNA should be detectable. To examine this possibility, labelled probes containing IS*1* and IS*2* were hybridised to Northern blots[8] containing total *E. coli* RNA which had been fractionated by electrophoresis on agarose gels. In a previous study, regions of limited homology between IS*1* and IS*2*, not ordinarily observable by solution hybridisation techniques, were readily detected by hybridisation to DNA restriction fragments blotted to nitrocellulose filters[9]. In the present study, total *E. coli* RNA was separated into its predominant 23S, 16S and 4–5S size components by agarose gel electrophoresis (Fig. 1, lanes *a*1, *b*1) and chemically bound to filter paper as described by Alwine and coworkers[8]. ^{32}P-labelled DNA from wild-type bacteriophage λ, λNNC$_{1857}$r14 (containing IS*1*), plasmid pBR322, and pBR322 which contains two-thirds of IS*2* plus a small segment of λ DNA was then hybridised to strips of filter paper containing the separated RNA.

The autoradiograms in Fig. 1, lanes *a*2, and *b*2, show the result of the hybridisations of λNNC$_{1857}$r14 (IS*1*) and pBR322 (IS*2*), respectively, to *E. coli* RNA. IS*1* hybridised pre-

dominantly to 23S rRNA and to a lesser extent to 16S rRNA. IS*2*, however, hybridised equally well to both 23S and 16S rRNA. Due to the exceedingly short half life and unique complexity of mRNA, this experimental approach would probably not detect similar sequence homologies with the less abundant messenger RNA fractions which are present on the filter between 16S and 4–5S rRNA. λ and pBR322 probes without the IS elements, isolated in an identical manner to those containing inserts, did not hybridise to the RNA. Furthermore, the purified RNA was treated with DNase before electrophoresis to exclude the possibility of chromosomal DNA contamination.

A large portion of the sequence of the 16S and 23S rRNAs from *E. coli* is known (ref. 12 and C. Squires, personal communication). Therefore, with the aid of a computer program devised by Korn and coworkers[13] we attempted to find the regions of homology by comparing the nucleotide sequences of the IS elements with that of the RNAs. Sequences homologous to large regions of IS*1* and IS*2* (greater than 25 base pairs) were found in both 23S and 16S rRNA (Fig. 2). In addition to the sequences shown, numerous shorter regions of homology were detected between the IS elements and the 23S and 16S rRNAs. These shorter sequences were found in clusters in regions which had extensive hyphenated homology. In the case of the 23S rRNA, the regions which can form secondary structure in the RNA (inverted, complementary repeats) involve the same sequences which have hyphenated homology with the IS elements. The regions of IS*1* and IS*2* found in 23S rRNA (Fig. 2II, III) correspond to the terminal regions of these IS elements.

The portions of the IS elements present in ribosomal RNA can be viewed as nucleotide sequences that have become stably integrated over the course of evolution. The IS elements, or sequences like them, could at one time have interrupted DNA sequences coding for ribosomal RNA; the sequences remaining in the rRNA could represent remnants left behind by imprecise excision or duplication. It is also possible that IS elements which interrupt ribosomal DNA genes are partly processed out at the RNA level.

The partial IS sequences detected in this study may represent regions that have been conserved because of a required role in ribosome function. For example, homologous regions between IS elements and ribosomal RNA could modulate the translation of mRNA carrying IS elements or portions of these elements. Messenger RNA carrying IS sequences could be recognised by the ribosomes by virtue of the sequence homology between the IS elements and 23S and 16S rRNA described here. Hybridisation between the putative IS-mRNA and the ribosomal region containing IS homology could alter an essential RNA–RNA or RNA–protein interaction within a region of extensive secondary structure in the ribosome, making the ribosome either more or less efficient. One consequence of this mechanism would be to protect the cell from insertions which would adversely affect essential functions. This type of mechanism, to circumvent gene inactivation due to IS insertion, predicts that portions of IS sequences should be found in mRNA. We therefore examined other known coding sequences for regions homologous to the insertion elements to determine if regions of partial IS homology resided in specific regulatory sequences. Significant regions of homology were found between IS*2* and ΦX174 DNA and IS*1* and a ribosomal protein gene cluster, as shown in Fig. 2.

To test whether homologous sequences similar to those shown in Fig. 2 for the IS elements, rRNA, ΦX174 DNA and the ribosomal protein gene cluster could be found between any large DNA or RNA, the nucleotide sequences of IS*1*, IS*2*, 23S rRNA, 16S rRNA, the plasmid pBR322 (ref. 14), SV40 DNA[15], and two histone genes[16] were compared with each other to identify regions of homology. The only significant regions of homology found, other than those shown in Fig. 2, were between IS*1* and IS*2* (ref. 9).

Homology between IS*2* and ΦX174[17] detected by computer analysis (Fig. 2, IV) was directly observed when labelled ΦX174 DNA was hybridised to a Southern blot containing IS*2* DNA. The region of the ΦX174 chromosome which is homologous to a 30-base pair nucleotide sequence in IS*2* DNA corresponds to the terminus of the overlapping *D* and *E* genes continuing through to the start of the *J* gene. As shown by Sanger and coworkers[17], this sequence contains a ribosome-binding site which is complementary to the 3′ end of 16S rRNA. Remarkably, the homologous sequence between ΦX174 DNA and IS*2* overlaps the region of homology between IS*2* and a region near the 5′ terminus of the 16S ribosomal RNA.

The 3,000-nucleotide sequence coding for a ribosomal protein gene cluster[18] includes the genes for ribosomal proteins L11, L1, L10, L7/L12, a portion of the gene for the β subunit of RNA polymerase, and two promoter regions (P_{L11} and P_β). A 95-base pair leader sequence before the first ribosomal protein (L11) structural gene contains a 23-base sequence which has dyad symmetry. A nucleotide sequence spanning the entire palindrome in this transcribed leader sequence was found to be homologous to a 29-base sequence in IS*1* (Fig. 2V). This homology is especially interesting in light of the observation made by Rak[10], who showed that *gal* RNA isolated from a mutant strain which contained an IS*2* insertion in the *gal* operon carried a short nucleotide sequence homologous to IS*2* DNA. The orientation of the insertion was such that it could act as a promoter of transcription. Because IS elements contain transcription and translation control sequences, it is possible that the type of homologous sequences found between IS*2* and the leader sequence in the ribosomal protein gene cluster represent recognition sites into which IS*1* and IS*2* can integrate and thus affect gene expression. This idea is supported by the fact that most of the IS*1* and IS*2* insertions into the *gal* operon occur in the leader sequence[19].

Several observations suggest a correlation between the potential for secondary structure in DNA and RNA and the regions containing sequences homologous to the IS elements: (1) the terminal regions of IS*1* and IS*2*, which are inverted repeats, have sequence homology with rRNA; (2) the sequence homology between IS*1* and the ribosomal protein gene cluster involves a palindrome in the leader region of the protein gene cluster; (3) the clusters of hyphenated homology between IS*1*, IS*2* and 23S rRNA correspond to the regions of putative secondary structure in the RNA. This correspondence between the location of IS sequences homologous to rRNA and the presence of secondary structure may have practical significance in the coordination of gene control throughout several levels of the regulatory hierarchy.

We thank John Sninsky, Russell Medford and Craig Squires for assistance in the computer analysis. We also thank Craig Squires for the gift of the 800 base sequence of 23S rRNA and for allowing us to analyse the unpublished region which he sequenced, M. Rosenberg for the pBR322 plasmid containing IS*2*, and Henri Buc, Ken Marians and Phil Silverman for useful discussions and critical reading of the manuscript.

Hen egg white lysozyme was the first enzyme whose structure was determined by X-ray crystallography[1]. The proposed mechanism[2-4] based on this structure involves the distortion of the saccharide residue (2-acetamido-2-deoxy-D-muramic acid, NAM) in the natural substrate[5] (an alternating β(1→4) linked oligomer of 2-acetamido-2-deoxy-D-glucose (NAG) and NAM residues) bound to site D in the binding cleft. The importance of substrate distortion has prompted numerous enzymatic[6], chemical[7], theoretical[8-12], and physical[13] studies, but there is little direct crystallographic evidence on the conformation of a NAM residue bound at site D. We now present the X-ray structure of the non-hydrolysed[13] trisaccharide NAM-NAG-NAM bound in subsites B, C, D. Our interpretation of the 2.5-Å resolution difference map does not involve distortion of this residue in site D. Comparison with the structure of the δ-lactone derived from tetra N-acetylchitotetraose ((NAG)$_3$NAL) bound to lysozyme[14] suggests we may be looking at a Michaelis complex.

Crystals of native hen egg white lysozyme (Sigma, lot L-6876) were grown by a vapour diffusion technique[15]. The crystals of lysozyme with the NAM-NAG-NAM(MGM) trisaccharide bound were grown by co-crystallisation from a solution of 8 mg of MGM and 15 mg lysozyme in 0.5 ml of 4% NaCl buffered with 0.1 M NaOAc at *p*H 4.5. The native and MGM-bound lysozyme crystals displayed remarkably different habits thus giving an early indication that MGM had been incorporated into the tetragonal crystals of lysozyme in spite of the relatively small binding constant, $3.6 \times 10^2\ M^{-1}$ (ref. 13). The unit cell dimensions of the native hen egg white lysozyme crystals are $a = b = 79.08$ (2) and $c = 38.02$ (1) Å, whereas those for the crystals of MGM bound lysozyme are 78.97 (2) and 38.25 (1) Å.

The structure factor amplitudes for both the native and the enzyme–trisaccharide complex were brought to the absolute scale using the scale factors determined from Wilson-type plots of the corrected intensity data[16]. The appropriately scaled data sets thus had an agreement factor of 0.120 ($\Sigma||F_{MGM}| - |F_N||/\Sigma|F_N|$) for 3,652 common reflections. The phases for the reflections of native lysozyme for the calculation of the difference map were those from the refined tetragonal structure which had a conventional R of 0.23 (refined phase angles supplied by Ms D. Grace). Initial examination of a difference mini-map contoured at intervals of 0.03 e Å^{-3} starting with ±0.10 e Å^{-3} confirmed binding of the substrate MGM to sites B, C and D of lysozyme. Detailed analysis of the map and fitting of the model to the electron density were carried out on an MMS-X interactive graphics system devised by David Barry of Washington University. The model of MGM used for fitting was constructed by docking the atomic coordinates of two crystal structures: β(1→4), α-*N*,*N*′-diacetylchitobiose (monohydrate) by Mo and Jensen[17] and *N*-acetyl-α-D-muramic acid by Knox and Murthy[18]. The atom numbering scheme for MGM is given in Fig. 1*a*.

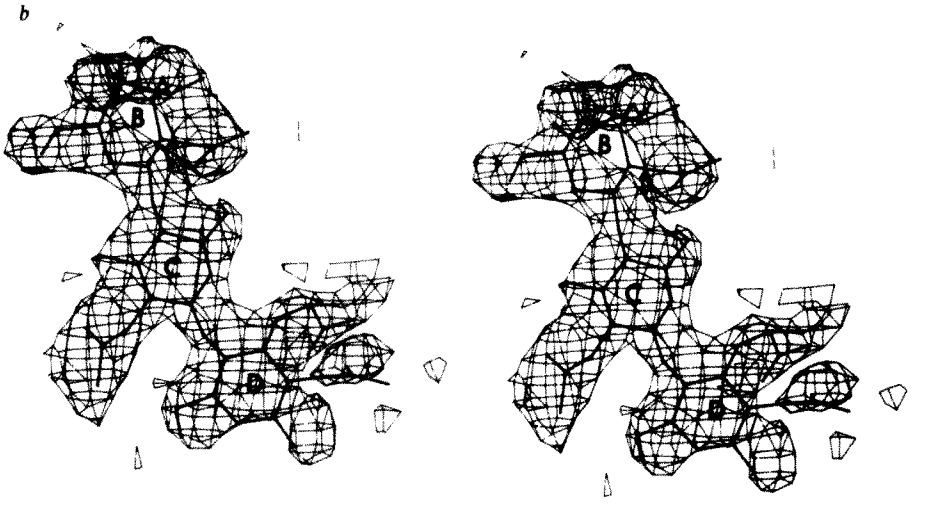

Fig. 1 *a*, The atomic numbering of the molecule of the trisaccharide, NAM-NAG-NAM, that was used in this study. Crystals of the NAM-NAG-NAM bound form of lysozyme were grown by co-crystallisation of MGM and lysozyme. Intensity data were collected from a crystal of native lysozyme and from a crystal of the MGM bound form on a Packer FACS-1 diffractometer[19]. Data from 10.0–2.5 Å resolution were measured from two symmetry equivalent (hkl and khl) reflections of each crystal. After correction of each data set for absorption[20] (maximum correction 1.31 for the native crystal; 1.51 for the MGM bound crystal), radiation damage[21] (maximum decay correction at $2\theta = 36°$ was 14% for native and 25% for the substrate bound crystal) and Lorentz-polarisation correction[22], the two symmetry equivalent reflections were averaged. The symmetry equivalent agreement indices for the intensity data thus measured are 2.86% for the MGM/lysozyme crystal and 2.30% for the native crystal. *b*, Stereoview of the difference electron density distribution ($|F_{MGM}| - |F_N|$), α_N with the fitted model of NAM-NAG-NAM superimposed. The sugar residues are labelled B, C and D to correspond to the binding sites on the lysozyme molecule[1-4]. This and subsequent figures were produced on an MMS-X interactive graphics system at the University of Alberta.

The model was initially positioned in the electron density by making use of prominent features of the well-defined density associated with the ring in site C, that is, C_6–O_6 and the 2-acetamido group (Fig. 1*b*). In this and all subsequent manipulations of the model into the electron density, only allowed rotations about single bonds were used. Ring puckers were all left in the $^4C_1$ chair conformation for the final fitting procedure. Attempts were made to fit the alternative conformations for the sugar residue in site D, which were discussed by Ford *et al.*[14] into the electron density associated with the trisaccharide MGM. All conformations other than the $^4C_1$ chair for this residue fit less well. In these latter trials, atoms C_1 or O_1 were positioned too far out of the electron density contour surface.

Fitting of the lactyl moieties of both rings B and D was problematic. Simple rotations about permissible bonds produced no better fit for either group. The bond angles at O_3 and C_9 were increased to try to move the lactyl groups into the flattened density. However, no improvement of fit was achieved, so these groups were left with standard bond angles and lengths.

The difference electron density map in the regions of the gluco-pyranose rings in sites B and D is affected by the displacement of several water molecules from the active site on trisaccharide binding. This phenomenon was also observed by Ford *et al.*[14] in the $(NAG)_3NAL$ difference map. Using the coordinates of water molecules associated with lysozyme as deposited in the Brookhaven Data Bank, we find that there is a water position 1.15 Å from C_2 of ring B and a second water position 2.11 Å from C_8 of ring D. Displacement of these two water molecules results in the poor distribution of electron density near these two atoms of MGM. A total of 10 water molecules are probably displaced by MGM upon binding to lysozyme; the distances between nearby atoms of the trisaccharide and these water positions in the native structure vary from 0.8 to 2.1 Å.

A second major feature of the difference map is a concerted shift of the main chain and side chain atoms from Gly 71 to Leu 75, which is relayed from the active site region via a hydrogen bonding network which includes Ser 72 O, Ser 60 O, Asn 59 Oδ1 and Arg 61 N. Concommitant with the binding of trisaccharide, the indole ring of Trp 62 moves towards site B and Trp 63 towards site C into a possible H bonding position with the carbonyl oxygen atom of the 2-acetamido group of NAG. A small shift of Trp 108 away from the substrate binding region is also suggested by this difference map. The magnitude of the main chain movement was obtained by fitting the difference density with the affected residues as a rigid unit on the graphics system. The difference in the coordinates between the native conformation and the shifted position was 1.8 Å. Similar conformational changes in these same regions of the lysozyme molecule have been described[23]. The binding of several acetamido monosaccharides have elicited movements of up to 1.0 Å in the region of amino acids 70–76. The shifts described by Perkins *et al.*[23] are, however, considerably smaller than the 1.8 Å movement indicated for those residues as a result of MGM binding.

The conformation of the active site of lysozyme with MGM bound is illustrated in Fig. 2. The most intimate contact between the substrate and the enzyme occurs in site C with the nitrogen of the 2-acetamido group hydrogen bonded to the carbonyl oxygen of Ala 107. Other stabilising hydrogen bonds and close contacts between MGM and lysozyme are listed in Table 1. This table also contains, for comparative purposes, those close contacts between lysozyme and the tetrasaccharide lactone[14]. The lactyl side group of the sugar in site B is in close contact with the native position of the guanidinium group of Arg 125 of a neighbouring molecule (related by $\frac{1}{2}-y, \frac{1}{2}+x, \frac{3}{4}+z$). However, there is clear indication in the difference map of the disruption of the intramolecular ion-pair between Asp 119 and Arg 125 which is present in the native lysozyme structure but prevented from forming when MGM is bound. Coordinates for the fitted model of MGM have been deposited with the Brookhaven Data Bank.

Catalysis by hydrolytic enzymes is described most simply as the lowering of the activation energy barrier of the rate limiting step by the enzyme providing a surface complementary to the substrate geometry at the transition state. How this lowering of the activation energy barrier is achieved is the subject of much discussion. It is quite likely that there are a number of factors involved, some more important than others. The lysozyme mechanism has run successively through several of these factors[3,4,9,10], and it has been suggested that electrostatic stabilisation is the most important contributor to the rate enhancement[11,12]. Stabilisation of the positively charged carbonium ion intermediate of the NAM residue in site D of lysozyme is made by the carboxylate ion of Asp 52, with little distortion of the glucopyranose ring in site D away from the $^4C_1$ chair conformation. On the other hand a crystallographic study of the tetrasaccharide lactone, NAG_3NAL, complexed to lysozyme[14] shows that the δ-lactone is in a conformation close to a sofa and in this conformation the ring atoms C1, C2, C4, C5, O5 are coplanar. It would appear that the lactone does mimic the previously proposed[4] carbonium ion intermediate[14]. The measured association constant of $3.3 \times 10^6\ M^{-1}$ for the lactone is also supportive of this view[24].

The relationship of the binding of the transition state analogue[14] (NAG_3NAL) to the binding that we observe for the trisaccharide MGM is shown in Fig. 3. Also included in Fig. 3 are the positions of the two catalytic residues Glu 35 and Asp 52. It is evident from this Fig.3*a* that the whole trisaccharide penetrates much less deeply into the active site cleft of lysozyme than does NAG_3NAL. The root mean square deviation of the 43 common atoms between these two molecules in their respective binding modes is 1.23 Å (sites B, C and D). The view in Fig. 3*b*

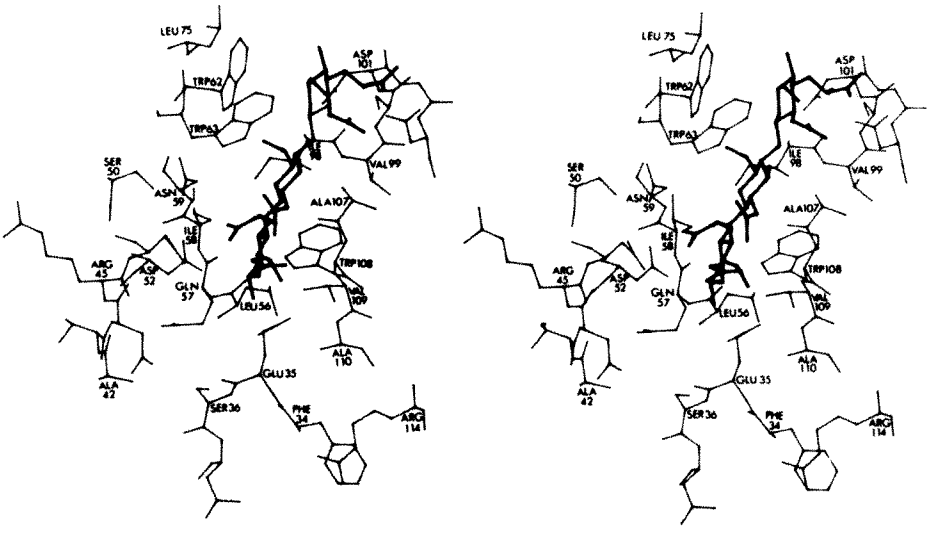

Fig. 2 The active site region of lysozyme with NAM-NAG-NAM bound (heavy lines).

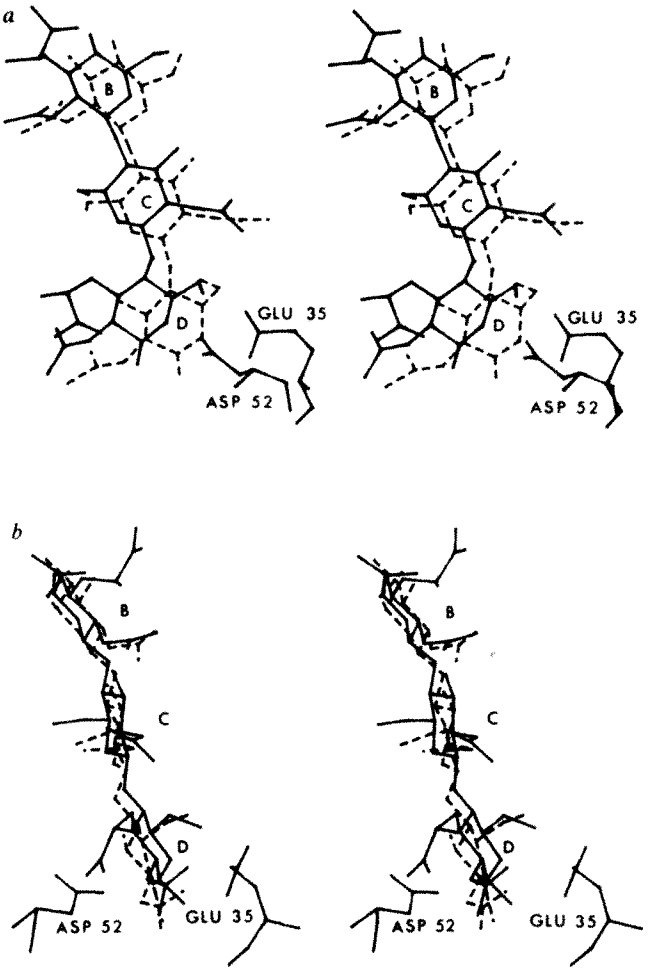

Fig. 3 The difference in the binding modes of MGM (solid lines) and NAG_3NAL (dashed lines) to the active site cleft of lysozyme. Only those residues in sites B, C and D of the tetrasaccharide NAG_3NAL are indicated. The active site residues Glu 35 and Asp 52 have been included to establish the relative orientation of these saccharides to the lysozyme molecule. Comparison of the two orthogonal views *a* and *b* shows that the tetrasaccharide transition state analogue NAG_3NAL penetrates more deeply into the cleft than does MGM. The NAM residue in site D is even further out of the binding site than the lactone ring.

indicates that there is little relative displacement in a direction perpendicular to the opening of the cleft. The NAM residue in site D is even further out of the cleft than the corresponding atoms of the lactone. On this basis we suggest that the binding orientation we observe for MGM may be characteristic of an initial Michaelis complex with the enzyme. Holler *et al.*[25,26] have observed the formation of stable productive complexes of chitohexose with lysozyme and have suggested that these complexes are subsequently transformed into reactive complexes. It seems clear that the productive binding and conversion to a reactive complex can only be achieved with the additional binding energy provided by the interaction of two more hexose units to sites E and F on lysozyme. Formation of this reactive complex is therefore associated with general acid catalysis by Glu 35 and electrostatic stabilisation[12] of the ensuing transition state carbonium ion by Asp 52.

The mode of binding we observe for MGM is consistent with a number of facts. The association constant determined by Patt *et al.*[13] is considerably smaller than that of the lactone. Part of this stems from the fact that in the lactone, site A is also occupied by a NAG residue. The remaining differential must stem from the observed differences in the binding modes as described. In the solution NMR study of the binding of MGM to lysozyme[13], it was concluded that there was no distortion of the saccharide bound in site D. The coupling constant studied, however, corresponds to the glucopyranose ring of the NAM residue in site D having the α-anomeric configuration at C1 (approximately 66% of the substrate molecules are α (ref. 27)). Binding of the β monomer could not be observed because the chemical shift of the β-anomeric proton is near the solvent peak in the spectrum. The α-anomeric configuration requires an axial hydroxyl group. However, there is no electron density which would correspond to an axial hydroxyl group (Fig. 1*b*). Thus, it would appear that the active site of lysozyme in the crystal is capable of preferentially binding the β-anomer in site D. Examination of Fig. 2 shows that if an axial OH were present in the *N*-acetylmuramic acid in site D there would be close contacts with the side chains of Asn 46 and Asp 52 which could be relieved, presumably, by a further rotation of the sugar ring out of its observed binding site.

Table 1 Comparison of close contacts between lysozyme and inhibitors*

Site	Protein atom	Substrate atom	Distance with MGM	Distance with NAG_3NAL†

Collagen molecules in native 66.8 nm (*D*) periodic fibrils are widely believed to be assembled into discrete, rope-like sub-structures, or microfibrils[1–17]. Several types of microfibril have been proposed (2, 4, 5, 7- and 8-stranded), mainly on the basis of information contained in the medium angle X-ray diffraction patterns of native tendon fibres[1,5–7]. These patterns show a series of equatorial and near-equatorial Bragg reflections which indicate that the collagen molecules are arranged on a three-dimensional crystalline lattice. The 4-stranded[11], 5-stranded[4–6] and 8-stranded[7,8] microfibrils are *D*-periodic with approximate diameter 3.8 nm, and these and the 2-stranded[10] model are supposed to be packed on a three-dimensional lattice whose basal unit cell, (approximately) perpendicular to the fibril axis, is tetragonal (or quasi-tetragonal) with side *a*, $a\sqrt{2}$ or $2a$, where *a* is ~3.8 nm. In this paper we describe a re-interpretation of the X-ray data[5,6] which leads to a new model for the crystalline regions of the fibril, based on quasi-hexagonal molecular packing without microfibrillar sub-structures, and hence having the character of a molecular crystal[18].

The crystallographic implications of combining hexagonal molecular packing[1,19–25] with the necessity for intermolecular $n \times D$ staggers[26,27] have been discussed[28,29]. Structures with regular D (and $4D$) or $2D$ (and $3D$) staggers in the three principal directions give rise to several types of crystallographic unit cells[29]; that suggested by McFarlane[28] has Bragg plane separations showing some agreement with the observed X-ray diffraction row line spacings[29]. However, some strong X-ray reflections are not indexed and, for those that are indexed, the discrepancies between observed and calculated spacings are greater than for the tetragonal indexing schemes. We now show that this type of model can be modified to give a good fit with the X-ray diffraction pattern. The X-ray pattern shows the most intense Bragg reflections on row line spacings $1/1.369\ \mathrm{nm}^{-1}$, $1/1.328\ \mathrm{nm}^{-1}$ and $1/1.264\ \mathrm{nm}^{-1}$ and, if it is assumed that these three spacings correspond to the principal Bragg plane separations in a slightly distorted (quasi) hexagonal packing scheme (Fig. 1), the agreement between the positions of the row lines predicted by the resulting unit cell and the observed data is excellent (Table 1). The unit cell is $a = 2.667$ nm, $b = 3.903$ nm, $\alpha = 104.58°$ and 17 of the 19 observed spacings are indexed with a standard deviation between observed and calculated reciprocal (or diffraction) spacings[17] of $0.004\ \mathrm{nm}^{-1}$ (compared with $0.010\ \mathrm{nm}^{-1}$ for the tetragonal indexing[6] of the same spacings). The two other, non-trivial combinations of the three principal quasi-hexagonal spacings give rise to unit cells which do not correspond so well to the observed data. The new unit cell predicts fewer unobserved row lines, in the range of the observed data, than any of the 5.4 nm or larger tetragonal cells. Furthermore, the strong intensity on the three row lines of approximate spacing $1/1.3\ \mathrm{nm}^{-1}$ is a natural consequence of the three principal Bragg plane separations in the quasi-hexagonal lattice.

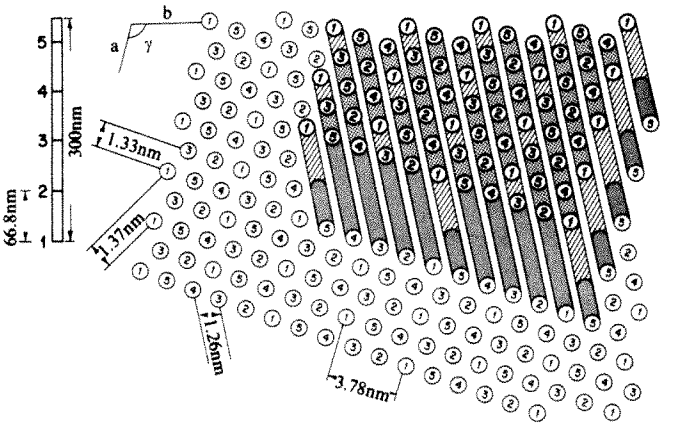

Fig. 1 Possible structure in one region of a collagen fibril, shown in projection down the fibril axis. Numbers refer to molecular segments (see upper left) in one 66.8 nm (D) thick transverse section. Thick shaded lines show molecular tilt and connectivity between upper (bold type) and lower (regular type) surfaces of the section. The molecular polarity and sign of the tilt (~5°) are arbitrary. In this example the lateral shift of the unit cell origin in height D is $\Delta a = a/10$, $\Delta b = -3b/10$. The same unit cell dimensions could also arise by regular combinations of two $1D$ (and $4D$) staggers and one $2D$ (and $3D$) stagger in the three principal directions, as well as by more irregular patterns of intermolecular $n \times D$ staggers.

The fanning of the near-equatorial reflections in the X-ray diffraction pattern indicates that the collagen molecules are inclined at a small angle to the fibril axis, either by tilting of straight molecules or by super coiling[5]. In the present model we propose straight molecular tilting, in such a way that the axes of the molecules lie in the 1.264 nm separated Bragg planes (Fig. 1). The molecules then appear tilted, by about 4°, when viewed perpendicular to the fibril axis along either the 1.369 nm or 1.328 nm separated Bragg planes. The tilting then accounts for the observed intense equatorial $1/1.264\ \mathrm{nm}^{-1}$ reflection and the intense off-equatorial reflections on the $1/1.369\ \mathrm{nm}^{-1}$ and $1/1.328\ \mathrm{nm}^{-1}$ row lines. Since the diffraction pattern arises from a large number of azimuthally disorientated fibrils, the off-equatorial reflections appear symmetrically on either side of the equator.

In general, hexagonal molecular packing of straight tilted molecules with intermolecular $n \times D$ staggers implies a lateral

shift in the unit cell origin in height D when viewed in projection down the fibril axis. This corresponds to lateral (perpendicular to the fibril axis) shearing of the three-dimensional unit cell and, for a given molecular tilt, the direction and extent of shearing is determined by the unit cell contents. Since lateral shearing of the unit cell in real space (the structure) corresponds to axial shearing (parallel to the meridian) of the reciprocal cell in reciprocal space (the diffraction pattern), reflections on the various row lines will be displaced parallel to the meridian. This effect could account for certain row line reflections indexing as non-integral orders of D, as is observed, for example, on the 1/3.8 nm^{-1} row line[5,6], though more detailed calculations will be necessary to account fully for features such as this. Lateral shearing and molecular tilt are illustrated in Fig. 1.

Table 1 Indexing of observed rat tail tendon row line spacings[6] with unit cell based on quasi-hexagonal molecular packing

Equatorial reflections have been observed on the 1/1.748 nm^{-1} and 1/0.964 nm^{-1} row lines. We note that these spacings index as $(1, \bar{2})$ and $(1, \bar{4})$ respectively in the present unit cell (Table 1), and thus correspond to Bragg planes which are almost parallel to the 1.264 nm separated Bragg planes $(1, \bar{3})$. Lattice sampling of the tilted molecular transform on these row lines would therefore be expected to give reflections very close to the equator, and these reflections may appear equatorial as a result of specimen disorientation (1.5°). This model therefore gives explicit account of the equatorial or off-equatorial occurrence of the most intense reflections in the near-equatorial part of the X-ray diffraction pattern.

The preceding discussion has assumed that the row lines are parallel to the meridian of the X-ray pattern. The data from native fibres, however, shows a small angular splitting for several row lines which indicates axial shearing in the structure[5–7,17]. From the identical angular splittings (±3°) of both the meridional and 1/3.8 nm^{-1} row lines[17], this shearing must be centred about the a axis. These data are only consistent with tetragonal lattices if there is no intensity on two of the four predicted 1/3.8 nm^{-1} row lines[17], whereas no such problem arises for the quasi-hexagonal model, in which only two 1/3.8 nm^{-1} row lines are predicted.

Observations in the region of the 1/0.95 nm^{-1} layer line (from the collagen triple helix) allow the relation between the molecular tilt and the axial shear to be specified. For native fibres, the intersection of the inner 1/3.8 nm^{-1} row line with this layer line occurs at a smaller distance from the equator than the intersection of the outer row line. This implies that the row lines are inclined in a direction opposite to that of the molecular tilt, as projected on to the plane of the axial shear. This interpretation is confirmed by the behaviour of these reflections during the so-called orthomorphic transition[5,17], in which the angular splitting of the row lines is reduced. The transition is accompanied by a shift towards the equator of both reflections representing the intersections of the 1/3.8 nm^{-1} row lines with the 1/0.95 nm^{-1} layer line, as predicted.

Density measurements offer a possible method of discriminating between the different molecular packing models[29]. These data are somewhat confused, however, by the relative insensitivity of the high angle equatorial X-ray spacing to the water content, in the region of 1/1.3 nm^{-1} (that is, when the 3.8 nm lattice is observed)[30,31]. Since it is difficult to imagine how water could enter the fibril without altering the equatorial X-ray spacing this observation has been interpreted as representing an increase in the interfibrillar water content[30]. Thus, taking a lower limit for the water content at an equatorial spacing of 1/1.31 nm^{-1} (that is, the centre of the '1.3 nm triplet') of 0.6 g water per g collagen[31], and assuming an average dry collagen density[30,32,33] and intrafibrillar water density of 1.36 g cm^{-3} and 1 g cm^{-3} respectively, the proportion of the intrafibrillar volume occupied by collagen in native rat tail tendon fibrils is approximately 55%. Table 2 shows that the relative exclusion volumes of the various packing models are distributed over a wide range, with the (quasi) hexagonal models showing the best agreement with the observed data. Independent support for hexagonal packing has been obtained using a molecular probe technique[24].

Table 2 Relative exclusion volumes for the different packing models

Basal unit cell			Model	Volume of fibril occupied by collagen
a (nm)	b (nm)	γ(deg)		
3.847	3.847	90	Tetragonal packing of 5-stranded microfibrils[6]	37%
5.440	5.440	90		37%
7.694	7.694	90		37%
7.56	7.55	90	Tetragonal packing of 5-stranded microfibrils[17]	38%
2.7	4.12	109	Hexagonal packing of molecules[27]	57%*
2.667	3.908	104.56	Quasi-hexagonal packing of molecules	54%
2.62	4.02	109	Hexagonal packing of molecules[28]	55%*
5.5	5.5	90	Tetragonal packing of molecules[18] or 2-stranded microfibrils[10]	72%*
3.49	3.84	90	Tetragonal packing of 8-stranded microfibrils[7,9]	82%*

* Assuming the c axis is perpendicular to the a–b plane and equal to $n \times 66.8$ nm.

It should be emphasised that here we account only for the positions of the sharp Bragg reflections in the near-equatorial part of the X-ray diffraction pattern. The breadth of these reflections measured in a direction parallel to the equator indicates that the lateral extent of long-range order is ~100 nm (ref. 5). However, at least 50% of the intensity scattered by the specimen in the near-equatorial region lies between the Bragg reflections in the form of continuous diffuse scatter. The profile of this diffuse scatter[39] falls sharply away from the origin and

reaches a broad maximum at about $1/1.3\ nm^{-1}$. Since fibril diameters in adult rat tail tendon are in the range 8–550 nm (ref. 34), it may be concluded that some fibrils or parts of fibrils are crystalline and other fibrils or parts of fibrils are disordered. Alternatively the disorder may exist within the crystalline lattice itself. As the Bragg reflections show very little increase in breadth (as measured parallel to the equator) with increase in distance from the origin, this and the form of the diffuse scatter are indicative of a mixed crystal[35]—a crystal in which the crystal lattice is well developed but throughout which the unit cell contents vary. Variation in the azimuthal positions of the molecules in the unit cells would cause diffuse scattering. To determine whether this variation is static or dynamic requires measurement of inelastically scattered radiation in the Rayleigh or Brillouin regions[36] or measurements of nuclear magnetic resonance[37] which already have been interpreted as suggesting dynamic azimuthal movement of the molecules in wet tendon.

Therefore, based on a new interpretation of the X-ray diffraction patterns, we propose that, in the collagen fibrils of tendon, the molecules are tilted to the fibril axis and packed on a quasi-hexagonal lattice that is both laterally and axially sheared. Discrete, rope-like, microfibrillar sub-structures within the fibril are not required by the X-ray data, though the unit cell does contain the minimum D-periodic descriptive unit[38]. The data do not preclude specific cross-linking patterns which may define minimum structural units[3,11].

We thank Drs Romaine R. Bruns, Jerome Gross and Jean-Claude Jesior for encouragement, and MGH Medical Arts Department for help with the illustration. D.J.S.H. was supported by an EMBL Fellowship and by USPHS Research Grants AM3564 and EY02252. This is a publication from the Robert W. Lovett Memorial Group for the study of Diseases Causing Deformities (Mass. General Hospital and Harvard Medical School).

X-ray diffraction from the side-by-side model of DNA

R. J. Greenall, W. J. Pigram & W. Fuller

Department of Physics, University of Keele, Staffordshire, UK

An intriguing topological problem posed by the double-helical Watson–Crick[1] model of DNA is that of unwinding the intertwined strands during replication. Several workers have recently proposed novel side-by-side (SBS) structures for DNA[2–6]. In all these models the two strands are joined by complementary Watson–Crick base pairs and the antiparallel polynucleotide strands alternate between short segments of right- and left-handed helix, thus both reducing the amount of intertwining and alleviating the unwinding problem. We show here that there are unacceptable discrepancies between the observed diffraction pattern of B-DNA[7] and that calculated for the original SBS structure[2]. We also describe a simple modification of this model which resolves some of the more serious discrepancies. However, the agreement is still markedly inferior to that obtained for a Watson–Crick model of DNA.

The model of Rodley *et al.*[2] is the only SBS structure for which detailed coordinates have been published. This model can be considered as most similar to the B conformation of DNA and Rodley *et al.* claim that it can account for patterns of the B type. The B conformation has been observed in both crystalline fibres of lithium (LiDNA) and semicrystalline fibres of sodium DNA (NaDNA). After allowance has been made for the effects of molecular packing, the X-ray scattering from a DNA molecule in NaDNA is, within the limits of the data from these fibres, essentially identical to that from one in LiDNA, indicating a very similar if not identical molecular structure. There is, therefore, a compelling requirement that any SBS model be capable of accounting not only for the data from semicrystalline patterns but also the more extensive and precise data from crystalline fibres.

Rodley *et al.* proposed their model as typical of a whole family of SBS structures, the members of which might differ, for example, in the number of nucleotide pairs in the right- and left-handed regions. However, the crystalline B X-ray data are compatible with the orthorhombic space group $P2_12_12_1$. The symmetry elements of this group when combined with the non-space group systematic absences (when $h+k$ is odd and $l=3n$, where n is integral) indicate that each DNA molecule must contain at least one diad axis per five nucleotide pairs perpendicular to the helix axis and orientated along the a or b axis. This extra symmetry element requires that the number of nucleotide pairs in the right- and left-handed segments be equal.

In contrast to the claim by Rodley *et al.*, the value of the reliability index (for the agreement between the SBS model and the observed diffraction data) calculated by Arnott[8] suggests that the SBS model is in substantially worse agreement with observed data than the best model of the Watson–Crick type. It is not clear that a single parameter such as the reliability index is the best way of comparing models of this kind and we compare below the full molecular Fourier transforms of the SBS and Watson–Crick models. This approach allows the regions of the diffraction pattern where the most significant discrepancies occur to be identified and provides an essential basis for any consideration of possible structural refinement of the SBS model.

The model of Rodley *et al.* does not completely solve the unwinding problem as it is still helical. With a minimal distortion of the original coordinates, the structure may be treated as a 10-fold right-handed helix with 10 nucleotide pairs per residue and a pitch of 345 Å. There is 2-fold rotational symmetry within each residue so that the structural asymmetric unit consists of

© 1979 Macmillan Journals Ltd

five nucleotide pairs. The diffraction from such a structure is confined to layer planes with spacing $1/345$ Å^{-1}. Both the method of calculating the Fourier transform[9] and the correction for the effect of water in the fibre[7] have been described elsewhere.

A detailed comparison of the diffraction calculated for the SBS model proposed by Rodley *et al.* and that observed for the B form is illustrated in Figs 1 and 3. The diffraction pattern in Fig. 1 is in very close agreement with unpublished calculations of D. R. Davies (personal communication). It is immediately clear that this particular SBS model cannot account for the X-ray diffraction from crystalline fibres of LiDNA. This is because the translational repeat along the helix axis for the SBS model is 345 Å, whereas that required by the X-ray data is 34.5 Å (the value is actually 33.7 Å but this difference is not relevant to the argument). The only possibility for removing this major discrepancy would lie in the extremely unlikely event of a model of this type having a Fourier transform on all layer planes for which $l \neq 10p$ (where p is any integer, including zero) which was accidentally zero. Figure 1 shows that such a fortuitous occurrence is not the case for the published model coordinates.

The translational repeat of the SBS model would, however, be reduced to 34.5 Å (and the predicted diffraction thus confined only to layer planes which are actually observed) if the rotation per residue were 0° instead of 36°. A model with no net rotation may be thought to be biologically more attractive as the polynucleotide chains do not then intertwine at all. We have, therefore, applied a uniform distortion to the published SBS model to reduce the net rotation to 0°. This was achieved by reducing the atomic ϕ coordinates within the qth nucleotide of the repeating unit by $\frac{35}{10} \times (q-1)°$. This is a crude way of modifying the coordinates but it is quite satisfactory for examination of the calculated diffraction expected from this sort of model. The modified model can be regarded as a helical structure with one residue per helix pitch. As for the original SBS model, the residue consists of 10 nucleotide pairs with 2-fold symmetry. The transform of this model is plotted in Fig. 2.

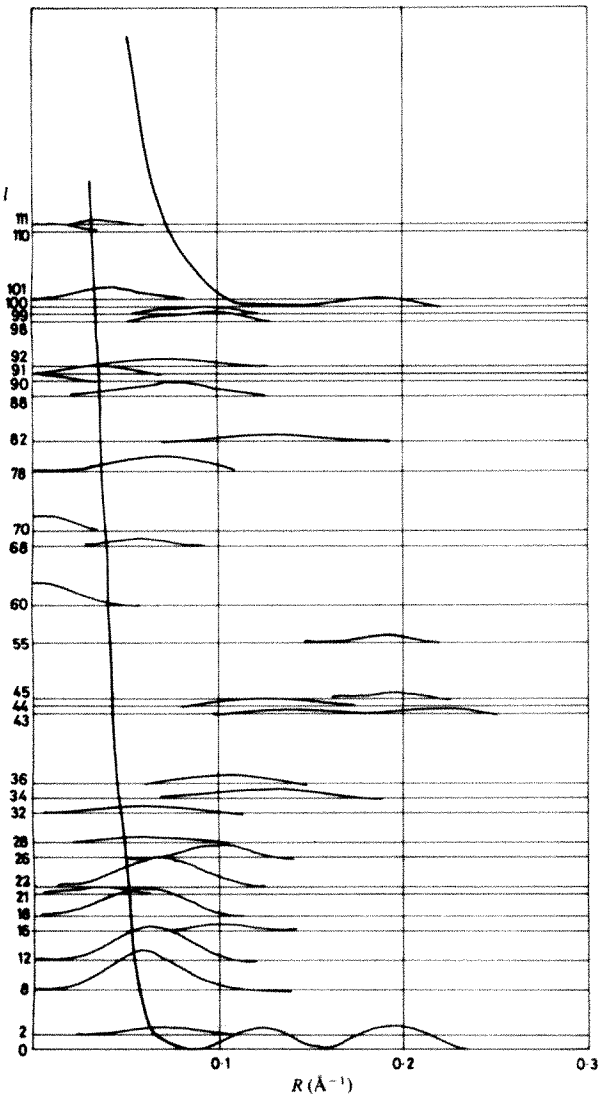

Fig. 1 Cylindrically averaged squared Fourier transform for the side-by-side model for DNA proposed by Rodley *et al.*[2]. The transform on each layer plane l is plotted as a function of the distance R from the centre of the plane.

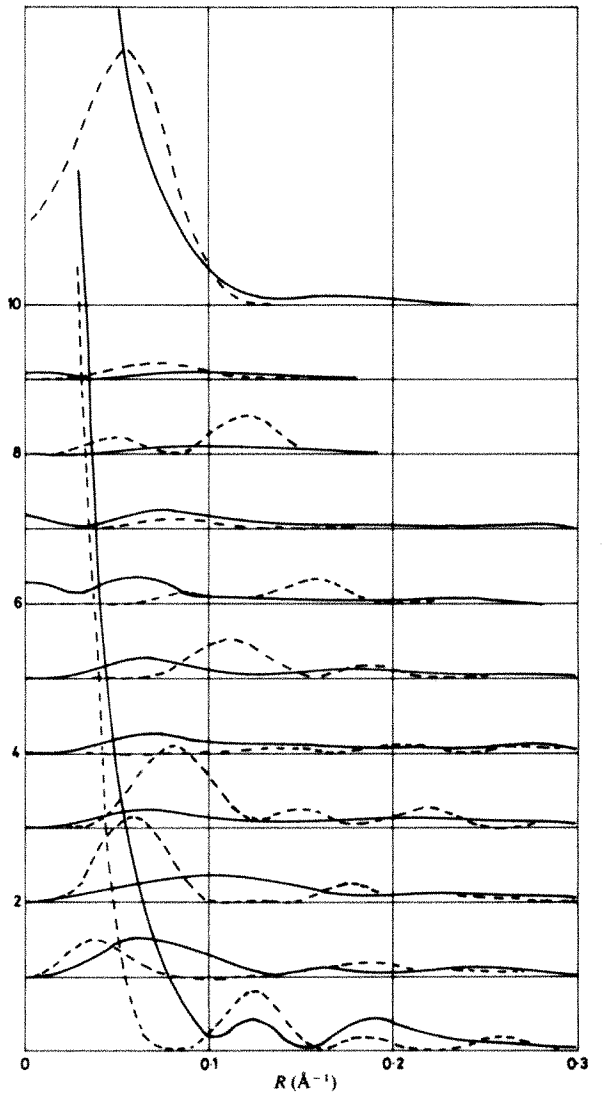

Fig. 2 Comparison of the cylindrically averaged squared Fourier transform of a distorted simplified version of the original side-by-side model (solid curve) with that of the Watson and Crick model for DNA described by Arnott and Hukins[10] (broken curve).

Figure 3 represents the level of agreement which was obtained between observed and calculated diffraction in the initial refinement of the Watson–Crick structure of crystalline LiDNA. The dashed curves in Fig. 2 represent the calculated diffraction for a further refinement of this structure using the linked-atom least-squares technique[10]. While there are significant differences between the diffraction calculated for these two

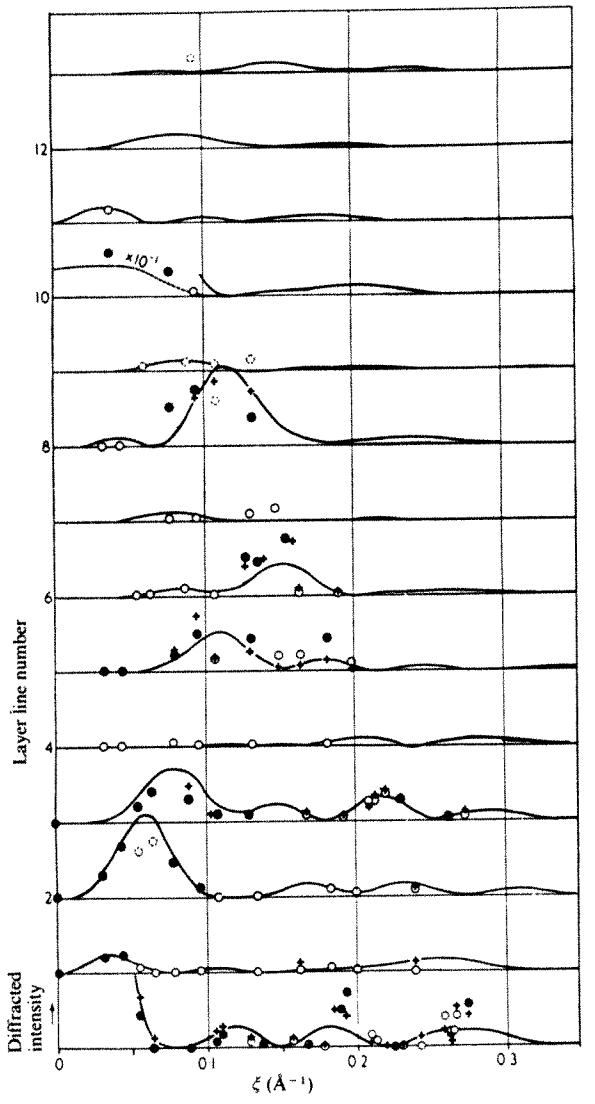

Fig. 3 Comparison of the cylindrically averaged squared Fourier transform of the Watson and Crick model for DNA refined by Langridge *et al.*[7] with the observed intensities. Observed intensities in order of decreasing reliability are indicated by ●, ○ and ◌. ξ is the distance from the centre of the layer line and is equivalent to R in Figs 1 and 2.

Watson and Crick models, the differences are not large and for both models the calculated diffraction is similar to that observed. Even the most superficial examination of Figs 1–3 reveals that the diffraction calculated for the two SBS models differs markedly from that observed.

A particularly serious deficiency of the original SBS model is the occurrence of diffraction on layer planes which are neither observed nor predicted by the Watson–Crick models, that is on $l = 8$, 12, 18, 22, 26, 78 and 88 in Fig. 1. There is no doubt that the quality of the X-ray diffraction patterns from crystalline fibres of LiDNA is sufficient for the original SBS model to be eliminated on the basis of the non-observation of these layer planes. The SBS model also predicts substantial meridional diffraction on layer planes $l = 60$, 70 and 90 (corresponding to $l = 6$, 7 and 9 in the normal B-DNA nomenclature). This is also at variance with the observed diffraction. In addition to predicting diffraction which is not observed, the SBS model fails to predict the strong diffraction which is observed on layer planes $l = 10$, 20, 30, 50, 60 and 80 ($l = 1$, 2, 3, 5, 6 and 8 in the normal nomenclature).

It can be seen from Figs 2 and 3 that while the distorted SBS model only predicts intensity on those layer planes for which diffraction is actually observed, the magnitudes of these predictions are seriously in error. Specifically, substantial meridional diffraction is predicted but not observed on layer planes $l = 6$, 7 and 9. Furthermore, the distorted model is seriously in error in its prediction of the relative intensity of diffraction on the various layer planes. These discrepancies are particularly serious on $l = 2$, 3 and 8 where the overall calculated intensity is much less than is observed and on $l = 4$ for which substantial diffraction is predicted where the observed intensity is essentially zero.

We may conclude that there are major and quite unacceptable discrepancies between the observed diffraction from the B form of DNA and that calculated for the SBS model proposed by Rodley *et al.*[2]. Although some of the more serious discrepancies can be removed by the simple distortion of the original model described here, the degree of agreement between observed and calculated diffraction is still very poor and very much inferior to that reported for the best models of the Watson–Crick type. It should also be emphasised that DNA can change reversibly within a fibre from a conformation that gives the semicrystalline B pattern to one that gives a fully crystalline A pattern[11]. This change is easily explained in terms of the Watson–Crick model by an increase in the number of nucleotide pairs per pitch from 10 to 11. Even if an SBS model could be found to account for the B diffraction data, it would also need to be capable of undergoing a stereochemically plausible transition to account for the A diffraction pattern.

This work was supported by the SRC.

Errata

The authorship of the article 'Crust of oceanic affinity in Iceland', *Nature* **281**, 347 (4 October) emerged incorrectly as a result of a misunderstanding between us and our typesetters on the telephone. It should have read:

Scientific Party, Iceland Research Drilling Project (I. L. Gibson, editor).

We regret this error.

In the letter 'Chlorophyll and nitrate fine structure in the southeastern Bering Sea shelf break front' by R. L. Iverson *et al.*, *Nature* **281**, 664–666, the units mentioned in the legends to Figs 3 and 5 should read: (μg atoms NO_3–N l^{-1}).

In the obituary to Dr Scott Mazzur, *Nature* **280**, 708, the new antigenic marker mentioned in the penultimate paragraph is the 'l' antigen, not the 'e' antigen as shown.

Synopses of the British Fauna (New Series) No. 17
edited by D. M. Kermack and R. S. K. Barnes

British Brachiopods

Keys and Notes for the Identification of the Species

C. Howard C. Brunton and Gordon B. Curry
January 1980, vi+64pp., £4.80 $11.50 0.12.357550.8

Today Brachiopods can be regarded as 'living fossils' found inter-tidally and in deeper water, from below antartic ice to tropical reefs. *British Brachiopods* deals with the British represenatives of this group of marine animals. Although less diverse today than in past ages, there are 21 distinct species found in the waters around the British Isles, all of which are described in this synopsis. Often called 'lamp-shells', brachiopods have been confused with bivalve molluscs. The book shows how this confusion can be avoided as the orientation of the shells is quite different in the two groups of animals. This synopsis will be of great interest to zoologists, palaeontologists and naturalists, and will encourage the search for these living remnants of a great fossil record.

Interferon Volume 1

Editor-in-chief: Ion Gresser
Board of editors: K. Cantwell, E. de Maeyer, M. Landy, M. Revel and J. Vilček

December 1979/January 1980, xii+164pp., £9.80/ $23.00 0.12.302250.9

INTERFERON has been introduced to provide a much-needed forum specifically for investigators from all disciplines working on interferon. This publication is neither a journal reporting the latest experiments nor an 'annual review', although it is intended that it will appear once a year. Rather the focus will be primarily on 'position papers' by international experts which will reflect the major issues and dominant themes in interferon research. The style will be personal and informal, and contributors will be encouraged to interpret for a wide audience their ideas, current work, aims and problems, to discuss and clarify controversial points, and to speculate on the prospects of future work. For anyone concerned with interferon this publication is a vital new source of information on the progress made, current issues and the goals still to be attained.

Experimental Archaeology

John Coles

December 1979/January 1980, c320pp.
Hardback: £10.80/ $25.00 0.12.179750.3
Paperback: £4.80/ $11.50 0.12.179752.X

This book picks out the major trends in experimental archaeology but the choice of work described is selective and represents the author's interest in archaeological experiment as an important means of retrieving and explaining evidence about early societies. The first chapter is an historical treatment of experimental archaeology, questioning the evidence and devising new approaches. The following chapters look at ocean voyages, the production of food and the building of houses, the manufacture and use of tools and weapons, achievements in arts and music, the erection of monumental structures for the dead and, finally, modern attempts to experience 'life in the past'.

Aspects of Consciousness

Volume 1: Psychological Issues

edited by Geoffrey Underwood and Robin Stevens
January 1980, xvi+252pp., £12.40/ $29.00

The two editors of this book are both psychologists, one with leanings towards the cognitive approach, the other following the physiological approach. This has resulted in a well-balanced book with diverse opinions represented as how best to describe consciousness. It also helps to indicate the common ground held by cognitive and physiological explanations in a variety of closely associated areas of research. This volume of *Aspects of Consciousness* brings together a variety of discussions on mental processes. They range across a broad spectrum of topics which are of current interest in psychology. Chapters on traditional subjects such as memory and thinking, discussions on relationships between sensory deprivation and consciousness, hypnosis which can be considered an altered state of consciousness and time perception. Theoretically interesting aspects of consciousness are also covered in chapters on the development of consciousness and absent-minded behaviour.

Energy Risk Management

edited by G. T. Goodman and W. D. Rowe

December 1979/January 1980, c400pp., £14.80/ $34.50 0.12.289680.7

The topics discussed represent selected thematic contributions made at the International Review Seminar held in September 1978, by the International Institute for Energy and Human Ecology of the Royal Swedish Academy of Sciences, and the Swedish Energy Research and Development Commission. Risk assessment problems are considered under five separate themes. The first part of the book broadly reviews the risk assessment approach — its advantages and its drawbacks — and highlights the more important problems for detailed treatment in the remaining four parts. The second part examines some of the special problems connected with risk data and their interpretation, while the third part deals with the difficult question of the so-called "real" risk assessment as opposed to perceived or intuitive reaction to risk by the public.

Behçet's Syndrome

Clinical and Immunological Features

edited by T. Lehner

December 1979/January 1980, xii+324pp., £16.40/ $38.00 0.12.442680.8

Behçet's syndrome is the term used to describe a combination of clinical features that almost always include oral ulceration and are associated with genital ulceration, skin lesions, arthritis, inflammation of the eye, and vascular and neurological manifestations. The aim of this book, which records the proceedings of a conference sponsored by the Royal Society of Medicine in London, is to assist the large number of specialists who may encounter one or more of the manifestations of Behçet's syndrome to make a correct diagnosis. The contributors describe in detail the various clinical manifestations, discuss the diverse therapeutic approaches and deal at length with recent advances in the immunological investigation of Behçet's syndrome.

Cognitive Processes in Spelling

edited by Uta Frith

January/February 1980, c550pp., £17.00/ $39.50 0.12.268660.8

The book opens up a new field of study on cognitive-linguistic skills, their development and their abnormalities. Dealing with English orthography — which is highly complex and therefore an ideal testing ground — it analyses many different aspects of the subject, including both word production and word recognition in spelling. It looks at spelling, as a skill and as a problem, in children, adult illiterates and highly practised spellers as well as in children with special problems such as dysphasia, deafness and dyslexia. Collections of spelling errors from normal and abnormal samples are provided for the reader to analyse, as well as new diagnostic tests. The comprehensive bibliography will be a useful guide to further research.

A Volume in the Mathematics in Science and Engineering Series

Applications of Functional Analysis and Operator Theory

V. Hutson and J. S. Pym

December 1979/January 1980, c400pp., £17.00/ $39.50 0.12.363260.9

This book guides the non-specialist through the beginnings of the subject towards both the principal achievements in linear theory and to certain areas of current concern in nonlinear theory — arguably the area where in practice functional analysis makes its most important contribution. The book has two aims. Firstly, through a careful selection of material, it provides essential abstract techniques for applications. In order to make this material more accessible the work contains more explanation than is normal in standard functional analysis texts. Secondly, the text shows how the abstract theory will work in practice. Gradually the theory is exploited to tackle problems which occupy a central position in applications. The book concentrates on what might roughly be described as "the solution of equations".

Advances in Microbial Physiology Volume 20

edited by A. H. Rose and J. Garreth Morris

January/February 1980, x+368pp., £19.60/ $45.50 0.12.027720.4

This series presents critical review articles on all aspects of the physiological and biochemical activities of organisms. *Advances in Microbial Physiology*, spanning the area between microbiology and biochemistry, is able to deal with subjects of interest in both fields which previously have received little attention from reviewers.

Contents

W. Ford Doolittle: The cyanobacterial genome, its expression and the control of that expression.
M. Young and J. Mandelstam: Early events during bacterial endospore formation.
Hiroshi Nikaido: The outer membrane of gram-negative bacteria.
Stephen A. Morse, Anthony F. Cacciapuoti and Paul G. Lysko: Physiology of *Neisseria gonorrhoeae*
Author index. Subject index.

Fibrous Proteins: Scientific, Industrial and Medical Aspects Vol. 1

edited by D. A. D. Parry and L. K. Creamer

January/February 1980, xviii+508pp., £19.80/ $46.00 0.12.545701.4

This is the first of two volumes based on the "International Conference on Fibrous Proteins: Scientific, Industrial and Medical Aspects", held at Massey University, Palmerston North, New Zealand, from 12-16 February, 1979. Fifteen eminent scientists were invited to present reviews of the current state of progress in their respective specialist fields. These reviews have been collected together in this volume, presenting the most comprehensive résumé of the subject available. The scientific, industrial and medical aspects of each of the following four subject areas are considered: muscle and meat, collagen and leather, keratin and wool and finally, "other fibrous proteins" such as elastin, fibrinogen and silk. The conference coverage ranged from the protection of wool from the degradative effects of bright sunlight, to recent advances in the sequencing and secondary structure of collagen.

Renewable Energy

Brent Sorensen

December 1979/January 1980, xviii+684pp., £19.80/ $46.00 1.12.545701.4

Bent Sørensen provides a much-needed source of reference for the facts, methods, principles and interrelations in the renewable energy field. The book discusses the origins of the renewable energy resources and gives models for assessing the environmental impact of their use. It estimates how much there is of each, and how efficiently energy can be extracted by different means, by evaluating the principal methods of converting renewable energy. It further discusses the composition and operation of energy systems, including renewable energy converters, storage facilities and an eventual fuel-based back-up system, and gives examples of system simulations. Finally, the adaption of economic theory to allow a fruitful socio-economic discussion of long-range energy planning alternatives is investigated.

Plants and Islands

edited by D. Bramwell

January/February 1980, x+460pp., £24.00/ $55.00 0.12.125460.7

Many scientifically valuable plants and animals are under serious pressure from the activities of man. This book is based on a symposium entitled Plants and Islands, held in Las Palmas de Gran Canaria in April 1977. Its aims are to draw attention to the scientific importance of islands, to review the present state of knowledge of insular floras, and to emphasize the necessity for further research on the taxonomy and biology of island plants, before it is too late. This book brings together, for the first time, the opinions of specialists on the origins, evolution, systematics and conservation of insular floras on a world scale. It will therefore provide a most useful source of reference for biologists interested in evolution, biogeography and conservation.

The Physiology and Pathophysiology of the Skin Volume 6

edited by A. Jarrett

December 1979/January 1980, c320pp., £27.20/ $63.00 0.12.380606.2

Volume 6 of this much-praised series continues the tradition of earlier volumes by providing reviews of literature within the broad field of dermatology. The range of topics already covered is extended by this volume to include, in three sections, the mucus membranes, the action of vitamin A on mucus membranes and the skin, and transepidermal water loss. Dermatologists, anatomists and physiologists, as well as those working in the fields of dentistry, gynaecology and food science, will benefit immensely from this comprehensive review. Medical and biological librarians and research workers in all these subjects will also welcome the recent findings described in this work, some of which are reported for the first time.

Form and Function in Birds Volume 1

edited by A. S. King and J. McLelland

December 1979, xii+470pp., £28.00/ $64.50 0.12.407501.0

This extensively illustrated, three-volume work is intended to provide a definitive account of avian morphology, surveying the principal anatomical features and showing how they work. The survey is not confined to the domestic species but covers birds generally. Evolutionary factors influencing avian morphology have been included where they help to clarify avian form. The overriding objective has been to show why birds are built as they are, rather than to provide an encyclopaedic catalogue of descriptive anatomy. The authors, drawn from Europe and North America, have adopted individual approaches in their chapters, placing varying emphasis on physiology, comparative vertebrate anatomy, and gross and microscopic anatomy; for purposes of continuity, however, the editors have tried to establish a reasonable uniformity of style. The anatomical terminology is based on the *Nomina Anatomica Avium*.

Nomina Anatomica Avium

An Anatomical Annotated Dictionary of Birds

edited by J. J. Baumel

January/February 1980, c600pp., £28.00/ $64.50 0.12.083150.3

The vast amount of anatomical detail and variety of form to be found in avian species has always suggested the need for a codified scheme of names for the various systems and anatomical parts of birds. With this in mind, the International Committee on Avian Anatomical Nomenclature was established in 1971 with a membership that soon grew to include some 80 eminent avian scientists. Their objectives in compiling the *Nomina Anatomica Avium* were to improve communication among avian scientists and to advance our anatomical knowledge of birds. To this end they adopted the universally acceptable language of Latin, chose one name where two or more are in current use, produced new names where none was available, replaced names that were grossly defective or inappropriate and codified the prevailing usage of satisfactory names.

Tropical Botany

Proceedings of a Symposium held at the University of Aarhus, 10-12 August 1978

edited by Kai Larsen and B. Holm-Nielsen

December 1979/January 1980, xii+452pp., £28.80/ $66.50 0.12.437350.X

This book contains a series of papers on tropical botany covering a rich field of knowledge, from plate tectonics and palynology and their importance for understanding the evolution of floras, to topics such as dispersal, evolution of species and pollination biology. For the first time all these subjects have been drawn together in relation to tropical vegetation, the most endangered plant community on the world's surface today. Contributors include outstanding botanists from major botanical centres such as the Royal Botanic Gardens, Kew, London; the Smithsonian Institution and The New York Botanical Garden; Laboratoire Phanerogamie, Paris; the Rijksherbarium, Leiden; and the Universities of Tokyo and Kyoto in Japan.

Advances in Electronics and Electron Physics No. 52

Seventh Symposium on Photoelectronic Image Devices

edited by B. L. Morgan and D. McMullan

January/February 1980, xvi+532pp., £32.60/ $75.50 0.12.014703.3

This well established publication is now edited to a different brief, resulting in a shorter but more concise and authoritative work. The Seventh Symposium was held at the Imperial College, London in September 1978. These symposia are the most important international conferences in this rapidly developing field. The papers give an account of the state of the art in detection and analysis of images by photoelectronic devices. Recent developments in television camera tubes and image intensifiers are included as well as the very important progress now taking place in solid-state detectors such as charge-coupled diode arrays and charge-injection devices. Professor Wilcock has written an introductory paper giving an overall view of the changes which have taken place in the field of photoelectronics during the last twenty years.

Proceedings of the Serono Symposia Series No. 15

Haemostasis and Thrombosis

edited by G. G. Neri Serneri and C. R. M. Prentice

December 1979/January 1980, xiv+800pp., £35.00/ $80.50 0.12.516150.6

This book is the edited proceedings of the first Florence Conference on Haemostasis and Thrombosis. This was a major meeting where specialists in the field of thrombosis and haemostasis convened to discuss advances in both the clinical and biochemical aspects of the subject. The wide range of topics discussed included blood coagulation — in particular fibrinogen and factor VIII biochemistry, interactions between platelets and vessel walls, fibrinolysis and its inhibition, effects of oral contraceptives, platelet pharmacology, and the current forms of treatment of clinical vascular and thrombotic disorders. This volume will provide a most useful source of reference for research workers in this area while physicians, surgeons and biochemists working in allied areas, will find here a comprehensive review of this important subject.

The Neurobiology of Dopamine

edited by A. S. Horn and B. H. C. Westerink

January/February 1980, xviii+724pp., £36.00/ $83.00 0.12.354150.6

The book ranges widely in its coverage, from the comparatively simple chemistry of the dopamine molecule to the complexities of its role in human mental illness. Between these extremes there are sections on the analysis of dopamine and its metabolites, on its biosynthesis, anatomical distribution and synaptic activity, and on the neurophysiology, behavioural functions and clinical aspects of dopamine containing systems. Each contributor has treated his topic at a level which will be comprehensible to those who are not specialists in that particular discipline. Anyone working on dopamine can now consult this book to learn of the full range of research recently carried out on all aspects of its neurobiology.

Modern Physics in Chemistry Vol. 2

edited by E. Fluck and V. I. Goldanskii

January/February 1980, xiv+638pp., £37.00/ $85.50 0.12.261202.7

Like its predecessor, this second volume aims to emphasize the contributions that the techniques described have made to the solution of chemical, physico-chemical and biological problems, rather than to detail methodology. The techniques offered apply to such fields as X-ray photoelectron spectroscopy, neutron diffraction, secondary ion-mass spectrometry, Mössbauer spectrometry and nuclear magnetic resonance spectroscopy. Some of the chapters deal with methods which have already found broad applications and here their authors draw the reader's attention to potential usage as well as providing references for more established modes of employment. Others cover methods — such as X-ray photoelectron spectroscopy and secondary ion-mass spectrometry — which have not yet found an entrance into chemistry on a broad scale and these chapters should break new ground.

Applied Fibre Science
Volume 3

edited by F. Happey

December 1979/January 1980, xx+552pp., £37.80/ $87.00 0.12.323703.3

Applied Fibre Science is the first work to provide a comprehensive survey of the methods used to study polymers and fibres, the appropriate areas of application of these methods and the present state of knowledge. The full range of polymers and fibres is covered, including the man-made and natural fibres used in the textiles, paper and other industries, the polymers produced in the plastics industry, as well as biopolymer research and its development in the field of molecular biology. Experts in the particular fields, selected on an international basis, have contributed to the work, giving it the broadest authority. Volume 3 is mainly concerned with the work that has been done on specific types of polymers and fibres.

Organophosphorus Reagents in Organic Synthesis

edited by J. I. G. Cadogan

January/February 1980, c580pp., £38.80/ $89.50 0.12.154350.1

In addition to the considerable practical importance of organophosphorus compounds for their own sake, for example as pesticides, antioxidants, or plasticizers, they have enormous value as general reagents in organic synthesis. It is to provide a summary of these applications that this monograph has been written. Considering the voluminous amount of literature on organophosphorus chemistry, it is all the more surprising that no such work of reference has yet been published. All researchers engaged in organic synthesis, industrial laboratories and university chemical libraries are bound to find this an invaluable work of reference.

Announcing a New Journal from Academic Press

European Heart Journal

The Journal of the European Society of Cardiology

Editor in Chief: D. G. Julian

Coronary Care Unit, Freeman Hospital, Newcastle upon Tyne, England

Assistant Editor: E. Sandoe

Medical Department B, Rigshospitalet, Blegdamsvej 9
2100 Copenhagen, Denmark

Proposed Editorial Board

H. Bleifeld, H. Denolin, Peter Harris, Paul G. Hugenholtz, Paul R. Lichtlen, J. Linhart, F. de Padua, P. Puech, A. Reale, Marko Turina, Lars Wilhelmsen.

Publication: Bi-monthly

Subscription: Volume 1, 1980
£23.00 (UK) $58.00 (overseas)

The journal is primarily intended for the publication of original work in cardiovascular medicine and surgery but important components of the journal will be reviews and notes in relation to recent developments in the field, for example, new drugs and techniques. It will publish reports from the European Society of Cardiology and its Working Parties and also from other supranational bodies such as the World Health Organization. Although published in English, it will be an international journal with its base in Europe. There will be periodic reviews of the non-English language literature from Europe and correspondence and book reviews will be regular features. *European Heart Journal* will prove an invaluable source of information for all those concerned with cardiology and it will take its place alongside other journals on this subject as an authoritative and scholarly work.

Contents of Volume 1 will include:

R. Michels, M. Haalebos, P. P. Kint, F. Hagemeiger, K. Balakumaran, M. Brand, P. W. Serruys, E. Bos and P. G. Hugenholtz: Intra-aortic balloon pumping in severe angina and infarction

G. R. Sutherland, R. H. Anderson, R. Heslope and S. Hunter: The value of sub-xiphoid approach in ultrasonic examination of the atrioventricular junction

Also: Report of the Working Party on Thallium and Blood Pool Imaging Collaborative Trial in the Prevention of Coronary Heart Disease, by the WHO European Collaborative Group.

Nitrogen-15 Nuclear Magnetic Resonance Spectroscopy

by **G.C. Levy**, *Florida State University*
and **R.L. Lichter**, *Hunter College, City University of New York*

This describes the characteristics and methodology, treating in detail ^{15}N chemical shifts, spin-spin (scalar) couplings, and relaxation parameters. In order to serve the needs of a wide variety of readers, the book is organized so that the qualitative discussions are followed by more extensive and quantitative treatments. It includes major developments appearing before February 1979, with several scientists providing previously unpublished material.

October 1979 — 232 pages
0471 02954 8 — $23.50/£10.75

The Molecular Basis of Optical Activity: Optical Rotatory Dispersion and Circular Dichroism

by E. **Charney**, *National Institutes of Health, USA*

A demonstration of how the phenomena of optical activity are treated by spectroscopists and theoreticians. Bridging the gap between chiroptical observations and underlying physical laws, this book emphasizes the treatment of optical activity as absorptive processes in which the radiation-molecule interaction results in a transition which carries the molecule from one quantum state to another.

Information Theory as Applied to Chemical Analysis

by **K. Eckschlager**, *Czechoslovak Academy of Sciences*
and **V. Stepanek**, *Technical University of Prague*

The first comprehensive monograph on the evaluation of results and methods in analytical chemistry by means of information theory. Treating chemical analysis as a process of obtaining information about the chemical composition of the analyzed sample, it discusses basic information concepts as well as most applications to chemical analysis. It covers probability theory, information measures and transmissions, statistical inference, and recent results in various analytical procedures utilizing information theory. Many examples illustrate both theoretical and practical discussions. *(Chemical Analysis Series No. 53)*

December 1979 — 204 pages
0471 04945 X — $25.95/£11.90

Handbook of Analytical Derivatization Reactions

by **D.R. Knapp**, *Medical University of South Carolina*

The author brings together practical information which has been previously available only in numerous separate sources. He begins with an overview of analytical derivatization methods which are organized according to the sample to be derivatized. A discussion of methods includes derivative type, reagent, sample type, reaction, and typical procedure with comments and references for each.

November 1979 — 762 pages
0471 03469 X — $46.50/£21.50

Chemodynamics: Environmental Movement of Chemicals in Air, Water, and Soil

by **L.J. Thibodeaux**, *College of Engineering, University of Arkansas*

This reviews existing knowledge in the natural and engineering sciences to determine the rates, lifetimes, routes, and reservoirs of chemicals moving through the environment and to estimate the level of exposure to susceptible living and nonliving targets. It uses simple models and ideas as guides in constructing integrated environmental and ecosystem models for simulating chemical movement and fate. Numerous problems from current literature are included.

December 1979 — 528 pages
0471 04720 1 — $39.50/£18.00

Soil Chemistry

by **H.L. Bohn**, *University of Arizona,*
B.L. McNeal, *Washington State University,*
and **G.A. O'Connor**, *New Mexico State University*

The authors examine inorganic soil chemical processes and apply processes to "problem" soils, as well as issues of localized and global nutrient availability and cycling. They discuss the relationship of soil to living organisms, the hydrosphere, and the atmosphere. Elements are organized into broad behavioural groups.

November 1979 — 346 pages
0471 04082 7 — $26.50/£12.50

Economic Mineral Deposits 3rd Edition

by **M.L. Jensen** and **A.M. Bateman**, *University of Utah*

A thoroughly revised, updated examination of the broad spectrum of world mineral deposits, with a vast amount of statistical data on production, reserves, and mineral resources. It contains new chapters on mineral economics and exploration and the newly recognized bacteriogenic and exhalative volcanogenic processes. Previous chapters on structural geology, geophysical techniques, extractive metallurgical processes, and ground water supplies have been eliminated while there are new tables and illustrations, and metric units of measurement.

December 1979 — 604 pages
0471 01769 8 — $28.75/£12.00

Resource Recovery and Recycling

by **A.F.M. Barton**, *Murdoch University, Western Australia*

Beginning with an explanation of the philosophy of resources recycling and the factors influencing its feasibility, this describes the physical, chemical and microbiological methods of separation and recovery. It presents applications in detail for postconsumer waste, including municipal waste, and for industrial and agricultural materials. Also considered are the thermodynamics of recycling. *(Environmental Science and Technology Series)*

September 1979 — 432 pages

Longing for simplicity

P. D. Moore

Plant Strategies and Vegetation Processes. By J.P. Grime. Pp.222. (Wiley: Chichester, UK, and New York, 1979.) £11.50.

IF there is one straw for which all biologists grasp, it is a clear conceptual framework upon which to hang the varied observations which form the raw material of biological research. No biological mind has equalled that of Darwin when it comes to the discovery of common denominators within disparate facts, but many have used a similar approach with varying degrees of success. In a science in which laws are statistical and exceptions are often commoner than the rule, it takes a brave man to make firm statements concerning the way in which living organisms are structured or behave in relation to their environment. That such statements are readily latched on to by the academic masses is evidenced by the current popularity of such concepts as *r* and *K* selection, or island biogeographic theory. We all long for simplicity in nature and embrace it firmly when it is shown to us.

J.P. Grime of the University of Sheffield is one of those people who has actively sought simple statements which can be made about nature and in particular about the various strategies which have evolved within the Plant Kingdom and which confer certain advantages upon those species possessing them. He conceives of three basic strategists: competitors, stress tolerators, and ruderals. He defines competition as the tendency of neighbouring plants to make use of the same resources; the competitor strategist is thus a species which, as a consequence of robust stature, fast growth rate and optimal timing of canopy expansion, is well fitted to obtain at least its fair share of those resources. Stress is defined as the external constraint upon the growth of part or all of the plant; the stress tolerator is thus a species which can continue its growth in conditions which might be expected to curtail the growth of others. Ruderal species are characteristic of disturbed habitats, where disturbance is defined as an interruption to plant biomass accretion. On the basis of this view of plant species, Grime proposes that three selective forces, *C* selection, *S* selection and *R* selection, are operative which had led to the evolution of the observed strategies. In attempting to reconcile this system with the currently prevailing *r*–*K* selective spectrum, Grime proposes that *R* selection is equivalent to *r* selection, *S* selection to *K* selection and that *C* selection occupies the intermediate part of the continum.

Having three, rather than two, defined endpoints in a classificatory scheme means that a simple one-dimensional ordination of species along a line is no longer appropriate and that, instead, one must think in triangular terms (an analogous model to the triangle of texture in pedology). In this way we can admit such bastard strategists as "stress-tolerant ruderals" and even "*C*–*S*–*R* strategists" which combine some features of all strategy types.

This system Grime regards as appropriate for any consideration of plants in their established phase. Upon it one must superimpose a further set of subdivisions based upon regenerative strategies, such as vegetative spread, soil seed banks, and so on. Having thus defined and explained his terms, the author then proceeds in the second part of the book to put them to the test, applying them to a consideration of various features and processes found in vegetation, such as dominance, coexistence and succession.

The real test of the value of this novel concept of vegetation is, of course, whether it assists in the explanation and understanding of observed phenomena. In this respect there are many pleasing features about Grime's model. One of its most successful applications, to my mind, is in the explanation of the high species density found in calcareous grassland, where low phosphorus and nitrogen availability can be regarded as a stress which limits the development of *C* strategists and permits the proliferation of *S* strategists and various non-competitive intermediate types.

Perhaps the least satisfactory aspect of the system is the loose definition of stress. The problem here is that what represents a stress for one species may be beneficial for another (take water-logging, for example). As most ecologists think of species as possessing bell shaped performance curves along environmental gradients, stress really has to be defined separately for each taxon, in terms of its optimum and performance limits. It cannot be defined in general terms.

Grime claims that his model is consistent with Odum's suggestion that the greatest diversity occurs in the middle range of a physical gradient, but this is not so. Odum considered that where conditions were least extreme, diversity would be highest. Grime claims that in such locations the *C* strategists would have a hey-day and plant species density would be low. Higher diversities would thus be achieved as one moves out from the centre towards physical extremes (there must be a better expression than "stress-gradient" for these axes). In this respect Grime's view seems to accord with reality more closely than Odum's.

This book is stimulating, refreshingly novel, controversial, perhaps a little oversimplified in places, but has one most valuable feature: it forces the reader's mind along new paths. He may not always completely agree with the author's views and conclusions, but he is sure to benefit from examining them. This freshness of approach, coupled with a concise and lucid style make this book a valuable tool for teachers of plant ecology. □

P.D. Moore is Senior Lecturer in Plant Ecology at King's College, University of London, UK.

Large scale magnetic fields

Cosmical Magnetic Fields. By E.N. Parker. Pp. 841. (Clarendon/Oxford University Press: Oxford, 1979.) £45.

ALTHOUGH the same basic physical principles apply to cosmical magnetised plasmas as to those produced in the laboratory, very significant differences arise in their application. Trapping of plasma in the laboratory is carried out with magnetic fields anchored to rigid conductors, and the aim is to produce equilibrium configurations. Astrophysical fields are trapped by gas, however, and gravitational forces give rise to magnetic buoyancy: dynamical activity seems to be the norm, rather than stable equilibrium, because of this absence of anchoring. These magnetic fields play important roles in determing conditions throughout the Universe, as they control the production and flow of the cosmic radiation, affect the accumulation of interstellar gas into clouds, and determine the radiation intensity of bremsstrahlung sources. It is clear that theoretical work would have been aimed entirely at understanding equilibrium configurations of magnetised plasmas in the cosmos if spatially unresolved sources had been the only ones

which could be studied. Observations of the Earth's magnetosphere and of the Sun demonstrate clearly that such studies are, however, too restricted: examination of these objects shows changes in magnetic structure in progress on a whole range of timescales which includes the 22 year magnetic cycle of the Sun and flares lasting minutes. These observations have provided an invaluable stimulus to the theoretician, though it is unfortunately the case that the changes observed are usually so complicated that it is difficult to decide which particular processes cause them.

Although many papers present detailed treatments, books on this rapidly developing subject have tended to illustrate the application of magnetohydroynamics by treating the basic concepts only. Thus, they have tended to provide brief idealised models of the solar dynamo, solar fluxes, sunspots, and the Earth's magnetosphere. Such treatments have been welcome because they provide insight into the basic problems, but it is necessary for workers to understand magnetic configurations more fully if they are to explain detailed changes in the radiation intensity from pulsar magnetospheres, accretion disks, supernova remnants, and so on. This book by Professor Parker is therefore invaluable because it illustrates clearly how largescale magnetic fields develop.

As mentioned earlier, observations of magnetic configurations on the Sun have stimulated theoretical work. Parker has been in the forefront of this work on interpretation for many years and his papers provide considerable insight about what is happening at various features. This book now provides a more systematic discussion with a series of chapters explaining the various configurations and processes. It must be stressed, however, that the author points out the relevance to non-solar studies, where applicable, and there are chapters devoted to magnetic fields of planets, and the field of the Galaxy.

The book begins with a chapter on the role of magnetic fields in the astronomical universe. This is followed by chapters on the nature of magnetic fields, the basic equations, magnetic stress and energy, and so on. One striking feature observed in high resolution photographs of the Sun is the non-uniformity of the atmospheric plasma, which generally shows a filamentary character. This reflects the presence of flux tubes as opposed to an 'equilibrium', large scale, continuous distribution treated in most theoretical work. Parker examines the formation of these tubes, their stability, and twisting of the structures. Magnetic buoyancy of the tubes and the activity which arises at the solar surface (and even within galactic structure) due to the absence of anchor points are also discussed.

Considerable attention has been given over the years to magnetic configurations where rapid relaxation of stress produces solar flares. This topic is discussed in chapter 15, but Parker also considers magnetic reconnection in any general topology where non-equilibrium fields have formed. The diffusion of flux through fluids of high electric-conductivity was once regarded as too slow for reconnection to be significant, but this has had to be reconsidered following laboratory studies of instabilities.

There are also chapters (18 and 19) dealing with formation of magnetic flux, which is a continuing process, as the primordial field has not remained trapped withing many of the regions which are accessible to observation.

Parker states in the preface that he intended individual sections to be intelligible without too much reference to earlier chapters. To this end, he begins most chapters with a concise and well-referenced discussion which places the particular problem in context. This is followed by a detailed analysis, and the chapter is terminated with a descriptive summary outlining the application of the work. Anyone wishing to follow the calculations will certainly require considerable knowledge of the techniques normally used in the field, but the assumptions made, and the conclusions reached, are set out qualitively in a clear, readily assimilated form. It is hardly the case, as the blurb states, that the non-scientist will find the material readable.

There has been a general reluctance to use SI units in astronomy, but the use of practical units in electromagnetism makes the SI system extemely attractive. In fact, the younger generation of scientists (in British Universities and schools, at least) are not familiar with gaussian units. The reviewer suspects that the adoption of SI by an author of Professor Parker's standing could have accelerated its adoption considerably. He is disappointed that the opportunity has been missed (while recognising that others will disagree), but regards the book as a valuable and stimulating contribution. **W.M. Glencross**

Social behaviour in insects

Social Insects. Vol.I. Edited by Henry R. Hermann. Pp. 437. (Academic: New York and London, 1979.) $36; £23.40.

GIVEN the role that the social insects (termites, ants, social bees and wasps) have played in the generation of sociobiological theory, a multivolume treatise which summarises our state of knowledge is indeed a welcome addition to the literature. This is the first of three multi-authored volumes. Volume 3 will be devoted to particular groups of insects, with chapters on honey bees, army ants, and so on. Volume 2 and this volume are more heterogeneous in content, with 2 covering communication, general reproductive behaviour, defensive mechanisms, pre-social insects, social spiders, and the systematics of social Hymenoptera and Isoptera.

The present volume consists of eight chapters, held together it seems only by the fact they they all deal with social insects. The authors represent not only a wide array of data, but an incredible diversity of opinion on certain key areas, an example being the "colony as superorganism" concept. I will return to this later.

Chapter 1 (by H.R. Hermann) serves to introduce the series. Hermann provides a brief review of animal behaviour studies and of the various social insects. It is suggested that studies of the genesis of insect social behaviour may be lumped into three categories . . . termed "genetic-behavioral", "serial-behavioral" and "anatomical". The "genetic-behavioral" approach refers to the kin-selection theory of W.D. Hamilton. "Serial-behavioral" and "anatomical" include phylogeneic sequences for the generation of highly social from less social forms. Here are discussed the excellent works of H.E. Evans and C.D. Michener. Although I found it hard to follow all the arguments, the section should be a good introduction to this literature. The conclusion which emerges? I quote from page 16: "Based on the various hypotheses summarized above, phylogeneticists are in obvious disagreement about phyletic associations and the sequence of events that led to a eusocial state in hymenopterous groups". I quote this to emphasise also the word hymenopterous. Isoptera receive barely a mention in this chapter. The chapter concludes with a review of various social traits, such as social dominance and territoriality.

Hamilton's kin-selection theory has been the major stimulation to recent work on the social insects, and this volume includes not just one, but two chapters devoted to genetical approaches to social behaviour. C.K. Starr is more biological, while R.H. Crozier goes more into the formal population genetics. Both chapters pretty much ignore the termites, in favour of the Hymenoptera, with their exotic male haploid (haplodiploid) method of sex determination. There is much overlap in the two chapters but this is a benefit as kin-selection theory is not so well defined as the popular literature would suggest. Both chapters provide good reviews of possible pathways for the evolution of helping or altruistic behaviour. Both provide discussions of haplodiploidy and its possible implications for eusocial behaviour. Crozier explains that haplodiploid population genetics is essentially the population genetics of sex-linked genes and discusses the implications of this for a variety of genetical problems.

These two chapters also treat R.D.

Alexander's "parental manipulation" theory for the origin of eusocial behaviour, but they both make the mechanism seem less likely or more difficult to achieve than is really necessary (see Charnov, *J. theor. Biol.* **75**, 451, 1978, for discussion). Finally, both chapters discuss the recent work of Robert Trivers and Hope Hare on sex ratio evolution within eusocial societies. Crozier's discussion is more detailed, with development of theory and plots of original data. Starr's discussion of the major prediction of the Trivers–Hare theory is incorrect. At the bottom of page 58, he lays out the conditions for the worker's equilibrium investment ratio to be 3:1. The statement should be that the workers lay none of the male eggs, rather than all of them, as he claims. These discussions of the Trivers–Hare theory should be supplemented with readings from more recent literature, omitted from this volume. I suggest particularly Alexander and Sherman (*Science*, **196**, 494; 1977) and Evens (*Bioscience*, **27**, 613; 1977). I found both these chapters quite thought provoking and it is nice to have all this 'genetical stuff' in one place. It should greatly facilitate the intellectual battles which make sociobiology so much fun: I challenge any first year graduate student to resolve the apparent theoretical conflict of Scudo and Ghiselin versus Levitt (see Table 5, page 266 in Crozier).

A short chapter by Carpenter and Hermann discusses the fossil evidence on the social insects. C. Baroni Urbani has contributed a very interesting chapter on applications of the concept of territoriality (a defended area in addition to the nest) to social insects. There seems to be good positive evidence for colony level territoriality in termites and ants. In ants much of the active defense is over food sources, so the territory becomes a defense of certain situations rather than a defense of a certain space or area. Territoriality seems to be rare in bees and wasps, with the exception perhaps of males and their mate search behaviour. Recent work by Johnson and Hubbel (*Ecology*, **55**, 120; 1974), however, has shown defense of food sources by stingless bees (not cited by the author).

G.C. Wheeler and J. Wheeler discuss their several (about five) decades of research into larvae of social Hymenoptera. The chapter contains detailed morphological descriptions and some astute suggestions as to the adaptive significance of various structures. They conclude with discussion on the role of larvae in the colony life. I was also charmed by G.C. Wheeler's following disclaimer "At this point I had better make my customary and necessary disclaimer: I am not related to William Morton Wheeler (the great ant biologist) — that is, not genetically. We were, however, closely related academically. G.C. Wheeler is close to defining a "cultural coefficient of relatedness" roughly defined as the fraction of ideas shared in common by two people. This seems to me to be a useful extension of kin-selection theory.

D.H. Kistner has provided a fascinating discussion of social insect symbionts — the other insects and mites which are found associated in various ways with insect colonies. His discussion of the means by which these guests deceive their hosts, the extent to which some are integrated into the colony life (and others are not, but still manage to keep from being killed) and the evidence on the phylogenic evolution of associations deserves careful study by all students of social behaviour and evolution.

M.V. Brian's chapter on "Caste Differentiation and Division of Labor" is a most imposing document. One hundred pages long with about 400 references, it documents what is known about the proximate control mechanisms for caste structure in all groups of social insects. This chapter fascinated me, both for what it left out as well as what it contained. Let me explain with reference to the concept of "colony as superorganism", a concept which appears throughout this volume. The question is: To what extent may we usefully consider a colony to be a single organism, with the queen as gonads and workers and larvae as somatic tissue geared up to aid the queen's reproduction? Hermann and Starr call it an outmoded and discarded concept. Crozier recognises that the analogy clearly breaks down at times (witness the queen-worker conflict notions of Trivers and Hare) but he is still willing to study theoretical models which explicitly assume it. He cites cogent criticism of the concept by Mary Jane West-Eberhard; criticism directed at E.O. Wilson, whose recent book, *Caste and Ecology in the Social Insects* (Princeton University Press: Princeton and Guildford, UK) with George Oster (for review, see *Nature*, **280**, 519; 1979) certainly does treat the colony as the unit of natural selection. If these authors seem to celebrate the demise of this concept, the chapters by Wheeler and Wheeler, and Brian clearly disagree. This brings me back to Brian's chapter. An excellent discussion of the proximate control mechanisms for caste structure, the chapter never mentions the fact that the reproductive interests of workers and queen must often diverge. Where their reproductive interests do not coincide, we might expect the mechanisms controlling worker behaviour to reflect this conflict and its resolution. Brian presents several instances of caste determination which could be usefully viewed in this way — from the perspective of conflict between workers and queen.

Clearly the authors of this volume (as well as E.O. Wilson and M.J. West-Eberhard) are in conflict over the superorganism concept. If it seems unresolved at present, so be it. Contrary to much popular opinion, the selective forces involved in generation and maintenance of social behaviour of insects are not yet clear. This volume represents very well the present search for underlying principles.

Eric L. Charnov

Eric L. Charnov is Associate Professor of Biology at the University of Utah, Salt Lake City, Utah.

Electron image processing

Image Analysis, Enhancement and Interpretation. By D.L. Misell. Pp.305 (North-Holland: Amsterdam, New York and Oxford, 1978.) Paperback $60; Dfl. 135. *Computer Techniques for Image Processing in Electron Microscopy.* By W.O. Saxton. Pp. 289. (Academic: New York and London, 1978.) £15.15.

THESE two books are the first single-author volumes to be devoted wholly to electron image processing, the practical importance of which has become gradually more apparent during the present decade. Despite the similarity in their titles, however, the books are very different in approach and intent. Saxton's is an advanced text, intended for readers already working in the field of digital image processing or for beginners about to immerse themselves in it. Misell's, on the other hand, is addressed to practising microscopists who wish to understand enough about image processing to know whether it could be useful to them. They may be biologists or materials scientists and much of each chapter is therefore written as qualitatively and unmathematically as possible; furthermore, what mathematical reasoning *is* given is cocooned in verbal explanation and definition. Saxton's book requires the mathematical sophistication associated with a degree in physics. One might thus say that Saxton's text is written for students eager to master what he has to offer, whereas Misell's is for an audience reluctantly obliged to acquire some familiarity with this young subject.

Turning to the contents, these too are by no means the same. Misell devotes considerable space to optical methods of processing images, and the book is therefore extensively concerned with periodic specimens. His book opens with a general account of the relationship between a specimen and its electron image, followed by a chapter on optical and computer image analysis, with particular attention to helical structures. A chapter follows on image processing; superposition and filtering techniques being explained in detail. Two chapters are then devoted to contrast enhancement. The first deals with instrumental techniques: defocusing, energy-filtered images, the use of STEM, dark-field and "optical shadowing",

among others. The second describes some simple computer procedures such as subtraction of pairs of images (one highly defocused), and histogram modification. In a final chapter, the author discusses the interpretation of images of various kinds and their reliability.

Misell has gone to great lengths to present all this material simply, with the result that most of the qualitative description will not be found difficult to follow even by readers unfamiliar with the jargon of the subject. The usefulness of the more mathematical parts of the text is much more questionable, however: on p41, for example, it is assumed that the reader will need to be told that "The i which precedes η in Eq. (3.12) is used mathematically to denote a phase shift in the exponential" and that $i = \sqrt{-1}$ (though this is not the first appearance of i). A few pages later, however, he is expected to be able to cope with two-dimensional Fourier transforms in vector notation, convolutions, delta functions and the like. The section on image analysis contains much helpful guidance on indexing diffraction patterns but not really enough to learn the subject: too little for the newcomer, too elementary for the instructed. This criticism is true of much of Misell's book: as a qualitative account of electron microscopy, biased towards periodic biological specimens, it is very clear and contains an immense amount of information; but as soon as an attempt is made to become more exact, it is unsuitable for those with little mathematical background and too elementary for those who may wish to implement the various techniques. Nonetheless, it was certainly well worth making the effort to write a text at this level and much of it will be found extremely helpful.

Saxton's book covers very different ground. An opening chapter is again devoted to generalities about electron image formation, and a short chapter sets out the properties of the discrete Fourier transform. The next five chapters, the heart of the book, are concerned with the question of determining the wave function of which the recorded image indicates only the modulus, the phase being lost. This problem is still being actively explored, though less energetically than during the first few years after the publication of the Gerchberg–Saxton algorithm, the first solution proposed, in 1972. The final three chapters are concerned with the hardware and programming of image processing, and include a description of the high-level language devised by Saxton to simplify the task of image processing on a large IBM computer. However, in view of the numerous subsequent developments and the introduction of a much-improved minicomputer version of the language (SEMPER) by Horner and similar languages in other image processing centres, this material has already drifted somewhat out-of-date. It is surprising that Misell does not deal with this topic at all, for potential users of digital techniques with no time or desire to learn much computing would surely be delighted to learn that simple languages are being devised to enable them to perform advanced processing almost effortlessly.

Saxton's book thus deals very fully with two branches of digital electron image processing: phase determination and picture handling. It is essential reading for anyone studying electron image interpretation, the phase problem in particular, and indeed, the analogous problem that arises in many other fields, optical coherence theory for example. It has the merit that not only is the theoretical support set out fully but numerical methods and computational trials are also described at length. Complicated though the subject is, Saxton has succeeded in writing a clear and highly readable acount and it is unfortunate that much of the intricate work from the Groningen group led by Professor H.A. Ferwerda appeared too late to be fully integrated into the text.

Both books are well-produced, and Misell's is particularly well illustrated, many of the images having been taken specially for this volume. One minor criticism of the latter is the use of "rad" as a radiation unit as well as "radian" — as SI is adopted everywhere else, why is radiation dose not given in grays? The severest criticism that can be levelled at Misell's volume is no fault of the author, however, for the only glaring inaccuracy occurs in the preface. There, Dr A.M. Glauert, the series editor, writes "each book . . . will also be available in an *inexpensive* edition for individual use . . ." (my italics); to describe a 300 page paperback in a successful series costing $60 as inexpensive, while a cloth-bound advanced text of much more limited appeal is priced at (only) £15.15, the series editor must somewhere have lost touch with reality.

Quantitative study of phytoplankton

Phytoplankton Manual. Edited by A. Sournia. Pp.337. (UNESCO: Paris, 1978.)

THIS book is the latest in a series of monographs on oceanographic technology initiated by the Scientific Committee on Oceanic Research of UNESCO. Although entitled *Phytoplankton Manual* the book is almost entirely devoted to marine phytoplankton, and only four pages are specifically devoted to freshwater phytoplankton.

A group of phytoplankton workers were called together, drew up the general arrangement and content of the volume and then handed over to the editor. In his introductory chapter the editor records the problems involved in drawing together such a work and he also indicates how difficult it is to get contributors to comply with deadlines. Also in the introduction the editor expresses a hope "that the present manual will provide a description and evaluation of all current methods". This is, of course, a fine objective but an impossible one as almost every worker has some refinement or variation which is considered to be an improvement for the conditions found in a particular area. This book does, however, cover another aim of the editor in that "an attempt has been made here to cover the quantitative study of phytoplankton at all stages of research, starting even before the act of collecting a sample (i.e., planning the study) and ending somewhat after the act of enumerating the organisms (i.e. interpreting the results)".

Consisting of a large number of short sections written by people with experience in working with phytoplankton, the methods are described in considerable detail and often compared with related methods, the book is a veritable mine of information. On the other hand because it does contain detailed descriptions of so many methods a young worker just starting in this field might be overwhelmed and find it impossible to decide which is the most suitable method to adopt. It should, however, prevent many of the initial errors which tend to detract from the value of the early results of inexperienced workers.

This, no doubt, will prove to be a valuable manual for all workers in marine phytoplankton, but I imagine a comparable one for the freshwater phytoplankton will also be required. If this book leads to a more uniform approach to the sampling, counting, statistical treatment and calculation of biomass of marine phytoplankton samples, it will have served a useful purpose.

The volume is clearly printed with few errors; it is strongly bound, although a more water-resistant cover may have been an advantage for a laboratory manual. There is an adequate list of references, a list of manufacturers of apparatus and a rather sparse index, but as the editor points out, with a chapter on "How to Use the Manual" the index does not need to be comprehensive. The price for a book of this size and containing so much practical information is extremely reasonable.

Thermodynamics and statistical mechanics

Thermodynamics and Statistical Mechanics By P.T. Landsberg. (Oxford University Press: Oxford, 1979.) £9.75.

IN this book, Professor Landsberg brings together thermodynamics and statistical mechanics to provide a coherent account of these interrelated branches of physical theory. The two subjects are treated sequentially in the text — a wise decision, as attempts to develop the two side by side usually result in the essential structures of both becoming obscured. The value of classical thermodynamics lies in what it can do without invoking microscopic models and it is best learnt by confining discussion initially to the macroscopic level. The terms of reference of Professor Landsberg's book are those of the physicist. In addition to including those topics common to most standard texts, there are chapters on fluctuations and transport properties, sections on negative temperatures and critical exponents, and introductions to irreversible thermodynamics and the theory of chemical reactions. The text also deals with subjects of current interest such as conversion and conservation of energy, black holes, and the early stages in the formation of the Universe.

Thermodynamics and statistical mechanics are both well established subjects so that any new text can only find justification if it has special merit in excellence of exposition or in its choice of emphasis. This book has some attractive features: sections containing core material are distinguished so that the reader may restrict his study to the central development if he wishes; worked solutions are given to the problems; and there are references to papers and comments on a selection of other books so that topics of interest may easily be pursued. The text is at its best (and it is then very good) in some of the sections dealing with particular applications; examples are the expanding universe, negative temperatures, and energy conversion. The general exposition, however, is unsatisfactory. Professor Landsberg states that he is fascinated by the relationship between physics and mathematics; this fascination, however, has unfortunate consequences in the text. The language used in the basic development of the subjects is highly formal, and mathematical structure frequently precedes physical explanation of what the structure is being erected for. As a result, one sometimes has the impression that physical results are eventually produced rather like rabbits from a conjurer's hat. It was diverting to discover that the phase rule is the same as the Euler formula relating the number of vertices, edges and faces of a convex polyhedron; but knowledge of the fact gave me no new insight into the physical world. Is it necessary or even helpful to the typical student to be faced with density matrices, Hessian determinants, Pfaffians and the signs of symbolic logic? It is, in fact, difficult to imagine the kind of student who, coming with little previous knowledge of thermodynamics and statistical mechanics, could find this a good book through which to learn them.

There are other grounds for criticism. It is surprising to find no mention of thermodynamic temperature, no formal definition of the kelvin, no mention by name of the principle of equal *a priori* probability. It is confusing to find both chemists' wavenumber $(1/\lambda)$ and physicists' wavenumber $(2\pi/\lambda)$ used in different parts of the text. It is disconcerting to find important results such as the Maxwell Relations or general equilibrium conditions derived in problems at the ends of chapters. It is irritating to find the Carnot cycle being used in the text before it is defined, again in a problem.

The book is also disappointing as regards its production. Oxford University Press has chosen, presumably in order to keep down costs, to use photographic reproduction of typescript. This can give a text of entirely acceptable appearance providing that the typescript is meticulously prepared. Here, however, alterations are frequently all too visible; in some cases corrections have been made and symbols inserted in ink by hand; and, in at least one place, there is a gap in the text where words have been deleted.

There is some very good material in Professor Landsberg's *Thermodynamics and Statistical Physics*; but the style of his exposition will make it inaccessible to most students. It is a book to be dipped into by those who already know the subject, not a book to learn it from.

C.J. Adkins is Lecturer in Physics at the Cavendish Laboratory, University of Cambridge, UK.

Obesity models

Animal Models of Obesity. Edited by M.F.W. Festing. Pp. 258. (Macmillan: London, 1979.) £17.50.

SYMPOSIA proceedings are all too often fabulously expensive and hopelessly delayed in publication, so that their only logical home is the library of a well heeled insititute of scientific history. This volume — subtitled *MRC Laboratory Animals Centre Symposium No 1* — is the exception to that rule. Though not cheap, it is, by today's standards reasonable in price, and, to judge from its plastic dustcover, the publishers see its home as much in the laboratory as the library. And there it will be found, for it is an authoratative text which covers a major experimental field in nutrition and is likely to be the only repository for a great deal of useful technical information, like Derek Miller's recipes for energy-dense diets, or David Lovell's outstandingly lucid guide on husbandary techniques for colonies of genetically obese rodents. But it is more than a technical guide, it is a unique review of a fast growing field, and one in which biochemists, geneticists, immunologists and nutritionists all meet, to exchange information and to generate ideas.

The book succeeds in giving the impression of interaction, both because of Dr Festing's careful editorial guidance, reflected in, for example, the frequent cross references between chapters, and because the symposium on which it was based was a fairly parochial, virtually all-British affair, in which all the contributors have closely followed each other's work. This parochiality is a trait which I find stengthens, rather than weakens, the feeling of a debate, and it is made possible by the fact that Britain is a leader in obesity research.

The symposium was orignally entitled *Genetic Models of Obesity in Laboratory Animals* but the change in title here is more than justified by the extent to which a number of authors, particularly Miller, Stock and Rothwell, James *et al.* and Garrow, have turned away from the simple gentic models such as the *ob/ob* or *db/db* mouse and the Zucker rat, and studied 'dietary-induced obesity': that in which no simple genetic component can be discerned. It may be, as many authors claim, that these are more appropriate models for the study of obesity in man, which is, after all, the justification for all the work.

At the same time, however, the simple genetic models have a scientific attraction which increases with every new defect they are shown to possess. This volume brings out the multitude of differences that the single Mendelian recessive *ob/ob* gene gives rise to, and in reading it, it is difficult to resist playing the game that so obviously fascinates many of the authors: to fit this metabolic mélange into the single enzyme defect that genetical orthodoxy requires. The man who solves that puzzle will perform a scientific feat that is in no way diminished by the fact that it will not provide a cure for obesity. It is a prize which is there for the grabbing, and anyone who wants to pursue it could do no better than to start with this eminently readable text.

John Rivers

John Rivers is a Lecturer in Nutrition at the London School of Hygiene and Tropical Medicine, London, UK.

Chemistry of metal complexes

Metal Complexes in Organic Chemistry. By R.P. Houghton. Pp.308. (Cambridge University Press: Cambridge, 1979.) Hardback £21; paperback £7.50.

I ENJOYED reading this book; it is written in a concise manner and is a mine of useful information. Its complex chemistry is a little thin in places, but perhaps the dose is correctly adjusted to the organic chemists whom the book addresses. The author has done a remarkably fine job in bringing together and systematising the vast variety of interesting organic reactions made possible or more specific, catalysed, inhibited or altered in direction by the action of metal containing compounds.

The book is aimed at "advanced undergraduates, graduates at the start of a research career in organic chemistry and practising organic chemists who wish to learn more about the chemistry of metal complexes". It is an excellent book for that purpose, and must represent an enormous amount of work on the part of its author. Its main deficiency is a lack of reference to recent primary literature, obviously a matter of policy, but it does give reference to some 125 well chosen reviews.

In 308 pages it is quite impossible to catalogue all of the organic reactions mediated by metal complexes. Nevertheless the author has made a very comprehensive survey of reaction types -except olefin polymerisation, but Ziegler polymerisation of olefins does receive brief mention (page 244). Each type of organic reaction is profusely illustrated by examples, well set out in display formulae. This means that a mere inorganic chemist such as your reviewer was never at a loss to understand the nature of the organic materials mentioned in the text, even in the very few cases where the name did not convey to him the essential chemical structure intended — for example, "methylmagnesium carbonate" on page 104 is not the probably hypothetical MeMgO.CO.OMgMe, but methyl methoxymagnesium carbonate, MeOMgO.CO.OMe.

The first and second chapters are concerned with general principles of complex chemistry in their application to the explanation of organic reactions mediated by metal complexes. They are very useful chapters with emphasis on electronic effects relating mainly to σ- and π-donation by ligands, π-donation by the metal atom, relative metal-ligand affinities, steric effects, and coordination saturation. They indicate how these affect the egress of organic reagents to the metal, whether as strongly or weakly bound ligands, and how the reagents are polarised or otherwise activated to chemical attack. The rationalisation of the complex chemistry which is desired for the purpose of this book is good. It is only deficient in taking no account of ligand field theory, especially to explain the stabilisation of the higher valent states of such metals as iron, cobalt and nickel, for example, by thio and non-π-donor ligands (page 47) and in the explanation of differences between the light and the heavier transition metals. Some short outline of ligand field effects, with a reference to appropriate reviews by the late Sir Ronald Nyholm or L.E. Orgel would have been appropriate here.

The types of reactions covered in the text are much too numerous to mention in this review. They range from the venerable Fredel-Crafts alkylations catalysed by aluminium chloride to the recently developed homogeneous hydrogenation, carbonylation and decarbonylation catalyses based on the heavier Group VIII metal complexes with tertiary phosphines, carbon monoxide (and so on) as ligands. The use of metal complexes in organic chemical synthesis ranges from the simple separation and purification of organic products as ligands, through mediation in organic reactions by shifting equilibria in favour of the desired product, through ester hydrolyses, bond cleavages especially of the CH bond, subsititutions, isomerisations especially of alkenes, hydrogenations, additions and eliminations of various sorts. They are all there, with a strong emphasis on explanations in terms of established physical-organic chemical mechanisms. These are clearly set out and copiously illustrated.

Although I sense that the author lacks some feel for inorganic chemistry, for example, as in his assertion that aluminium chloride exists as Al_2Cl_6 molecules in the *solid* state (page 127) and his formulation of $[ReCl_3(NMe)(PEt_2Ph)_2]$ with a non-bonding electron pair on the nitrogen atom (page 96), the book is a text which I strongly recommend. It is well researched, organised and printed. It summarises beautifully the types of interesting organic reactions which occur on metal complexes and has a very useful 10-page index. At present-day prices it is good value at £21. I congratulate the author and his publisher on a unique and well produced book in an area of chemistry which has been surprisingly slow in catching the imagination of organic chemists.

Joseph Chatt

Joseph Chatt is Director of the ARC Unit of Nitrogen Fixation and Professor of Chemistry at the University of Sussex, Brighton, UK.

Neurophysiological offerings

Studies in Neurophysiology. Presented to A.K. McIntryre. Edited by R. Porter. Pp.440. (Cambridge University Press: Cambridge and New York, 1979.) £32.50.

THIS book, as it proclaims on its cover, is a collection of offerings from his former collaborators and students to a much-loved and respected Australian neurophysiologist, Professor A.K. McIntyre. Professor McIntyre was successively head of the Department of Neurophysiology at Otago and the Department of Physiology at Monash, which quickly grew into a hugely successful venture. The success of these two departments can quickly be appreciated by a glance down the star-spangled list of contributors to this book, many of whose names would be recognised (with enthusiasm, one hopes) by any undergraduate student of neurophysiology.

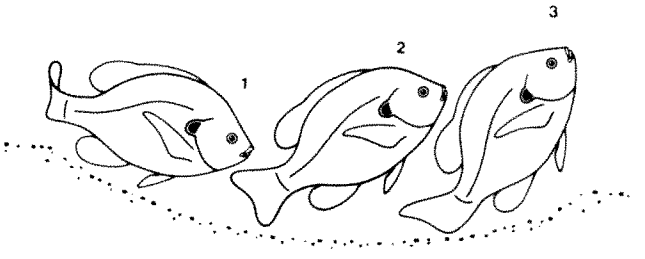
As an offering to Professor McIntyre, it must have given great pleasure; but how does it rate as a book about neurophysiology? The main difficulty in compiling such a book for publication as opposed to presentation is obviously to keep a coherent thread running through it, and to achieve consistency of style among the many contributions. Many of the individual contributions are, as one would expect, excellent. There are, for example, clear and elegant reviews of such topics as the vesicle hypothesis (Katz), the mechanism of excitation of carotid body chemoreceptors (Eyzaguirre & Fidone) and the functional significance of changes in extracellular potassium concentration in the central nervous system (Somjen). Other authors have chosen to give much more specialised and technical accounts of particular research projects (for example, Laporte on muscle spindle innervation, and Mubbard on the effects of angiotensin on brain neurones).

Towards the end another abrupt gear change takes place with a long and heady philosophical article by Trevarthen called 'Self-organising systems in psychobiology' (Typical headings: Is a mind biology possible?; Anatomies of imagery and intention; Normal duplicity of brains) which is followed by an essay on Claude Bernard and the *milieu intérieur.*

Though good in places, without a doubt, this collection amounts overall to an indigestible motley which might have been better kept as a private retirement present than expensively dressed up for publication. Unless you are in a sentimental mood, the outlay would be hard to justify.

H.P. Rang

H.P. Rang is Professor of Pharmacology at University College, London, UK.



New Books in . . .

Biology

M. H. A. Keenleyside

Diversity and Adaptation in Fish Behaviour

1979. 67 figures, 15 tables. XIII, 208 pages
(Zoophysiology, Volume 11)
Cloth DM 69,–; approx. US $ 38.00
ISBN 3-540-09587-X

The book investigates the behaviour of fish and the influence it has on their adaptation to a wide range of marine and freshwater habitats around the world. Topics under discussion are locomotion, feeding, anti-predator behaviour, the organization of fishes within groups, and reproduction. Separate chapters are included on spawning site selection and preparation, breeding and parental care. The book demonstrates the great variability within each of these categories, relating it to the ecological setting of the fish. The first comprehensive work of its kind, this book will be appreciated by ethologists, physiological ecologists, and fisheries biologists.

L. J. Fritschen, L. W. Gay

Environmental Instrumentation

1979. Approx. 76 figures. XVI, 216 pages
(Springer Advanced Texts in Life Sciences)
Cloth DM 42,–; approx. US $ 23.10
ISBN 3-540-90411-5

Up to now, students and specialists in forestry, ecology, agronomy and biological sciences have had to acquire their knowledge of the instrumentation needed for environmental measurements from numerous, scattered sources. *Environmental Instrumentation* presents this information in a unified, systematic treatment.
The introductory chapters provide an overview of measurement fundamentals and a review of the physical foundations of energy transfer and D.C.circuits. This is followed by a thorough discussion of the measurement of temperature, heat flow, radiation, humidity wind speed and pressure. The final chapter treats digital data acquisition, signal and noise.
Environmental Instrumentation is intended for all those interested in the interaction of biological organisms and meteorological factors. It can be used either as a text for senior level or graduate students or as a reference for environmentalists.

Springer-Verlag
Berlin Heidelberg NewYork

D. M. Gates

Biophysical Ecology

1979. Approx. 163 figures. Approx. 640 pages
(Springer Advanced Texts in Life Sciences)
Cloth DM 79,50; approx. US $ 43.80
ISBN 3-540-90414-X
Distribution rights for India: Narosa Publishing House, New Delhi, India

Biophysical Ecology presents an analytical treatment of the processes by which a plant or animal interacts with its environment. These processes include energy exchange, gas exchange, and chemical kinetics. A plant or animal interacts with its environment by processes which originate outside the organism, flow through the surface of the organism, and ultimately elicit responses through metabolic processes within the organism.
Energy exchange between an organism and the environment involves radiation, convection and evaporation or latent heat. Radiative exchange includes short-wave radiation such as solar, skylight, reflected a sunlight, and long-wave radiation from thermal emission by the ground surface, vegetation, clouds, and the atmosphere. A detailed description is given of the geographical, seasonal, and diurnal dependencies of short and long wave length radiation. The spectral properties of organisms and the environment are described. Analytical models of whole leaf photosynthesis and respiration are presented here for the first time.
Biophysical Ecology will be indispensable to advanced students in all life sciences. It is designed to provide an understanding of the ecology of organisms based on fundamental scientific principles.

Membrane Biochemistry

A Laboratory Manual on Transport and Bioenergetics

Editors: E. Carafoli, G. Semenza
With contributions by numerous experts
1979. 45 figures, 4 tables. X, 175 pages
DM 27,–; approx. US $ 14.90
ISBN 3-540-09844-5

The editors of this book, themselves well-known experts in the field, have assembled a broad spectrum of experiments in membrane transport and membrane bioenergetics. Basic techniques, as well as new and more sophisticated procedures are described in detail, with special attention paid to those which can be applied to a wide range of projects. The methods presented enable even readers with little knowledge of membrane biology to carry out correctly the most important experiments in the field.
The experiments reported have all been successfully tested in the Advanced Courses 29, 41, 45 and 52 of the Federation of European Biochemical Societies for Membrane Biochemistry, Transport and Bioenergetics, organized by the editors at the Swiss Institute of Technology, Zurich, between 1975 and 1978.

Geology

D. A. Ross

Opportunities and Uses of the Ocean

1979. Approx. 145 figures. Approx. 320 pages
Cloth DM 39,50; approx. US $ 21.80
ISBN 3-540-90448-4

Contents: Opportunity of the Ocean. – How the Ocean Works. – The Legal Aspects of the Ocean. – Marine Shipping. – Resources of the Ocean. – Pollution of the Ocean. – Military Uses of the Ocean. – Coastal Zone Divisions, etc. – Innovative Uses of the Ocean. – References.

AMBIO A JOURNAL OF THE HUMAN ENVIRONMENT

Now distributed for the Royal Swedish Academy of Sciences by Pergamon Press

Launched in 1972, AMBIO is already recognized by many as the leading interdisciplinary periodical in the environmental sciences.

Now, with the aim of broadening an already international coverage and readership, AMBIO will be published and distributed through a joint arrangement between the Royal Swedish Academy of Sciences and Pergamon Press.

Regular issues contain general articles on current environmental problems and challenges and reports on original research in the field. Special issues give a more comprehensive treatment of some topical subjects, e.g. issues are planned on the Baltic and threatened ecosystems.

" . . . The most authoritative journal of its kind on international environmental problems."
GILBERT F WHITE, *President, Scientific Committee on Problems of the Environment, I C S U*
" . . . AMBIO is the best magazine of its kind."
IGNACY SACHS, *Centre Nationale de Recherche sur L'Environnement*
"It conveys the message on crucial environment issues in the most accurate and well-presented way."
MOSTAFA K TOLBA, *Executive Director, UNEP*

FREE SPECIMEN COPY AVAILABLE ON REQUEST
Published 6 issues p.a.
Annual subscription (1980) US$60.00 Two-year rate (1980/81) US$114.00 Individual rate US$25.00

Prices include airmail postage and insufance and are subject to change without notice.

THE MACMILLAN DICTIONARY OF ASTRONOMY

Valerie Illingworth

This Macmillan Dictionary reflects the explosive growth of astronomy in the last few years. It contains up-to-date references to the many exciting developments and discoveries that have been made in these years as well as to established theories.
It is a concise and comprehensive work; fully cross-referenced, it contains illustrations and diagrams making it the ideal personal reference book for both the specialist and the interested layman.
£8.95 0 333 13263 1

obituary

Samuel A. Goudsmit, 1902-1978

On 4 December 1978 the world of physics lost one of its most unusual and interesting members when Professor Samuel A. Goudsmit died of a heart attack on the campus of the University of Reno, Nevada. His career was as varied as the times in which he lived; and the changes in science and scientists are accurately mirrored in his actions and his life.

Samuel A. Goudsmit was born in The Hague, The Netherlands, on 11 July 1902; he lived and grew up in a middle class family of merchants. At an early age he showed extraordinary mental agility. He was exceptional in solving puzzles of all kinds. When a young man in high school Goudsmit happened to get a hold of a cheap spectroscope (it presumably belonged to his older sister) and after examining the brilliant spectral colours, Goudsmit was hooked, and spectroscopy and the physics going with it became not only his interest, his hobby and his profession, but a lifelong passion.

Because of his interest first in spectroscopy and later in physics as a whole he started his studies at the University of Amsterdam. After receiving an intermediate degree he went on to obtain his PhD at the University of Leiden. Although Goudsmit's performance was brilliant (with some notable exceptions when he had no interest in the subject) he was considered somewhat of a failure by his family. Physics at that time was a calling, not a profession; with the certainty that there would be no jobs after completing the degree, it was reasonable that Goudsmit's family had a difficult time understanding his devotion to physics. In spite of his unquestioned early successes he was considered as a bit of a misfit.

At the university Goudsmit did well — in physics he did exceptionally well. He was only 19 years old when he pointed out in a paper, (*Naturwiss* **9**, 995, 1921), that the Sommerfeld formula for x-ray doublets was equally valid for alkali doublets. The knowledge, but perhaps even more, the scientific maturity necessary for that observation is highly unusual for a beginning student.

In Leiden, Goudsmit came under the spellbinding influence of Ehrenfest. Ehrenfest was impressed by Goudsmit's talent and interest. The combination of Ehrenfest's insistence on precision and clarity and Goudsmit's natural flair for physics led to Goudsmit's surprisingly rapid development as a scientist. It is therefore understandable that when another one of Ehrenfest's students, George Uhlenbeck, returned to Holland (from a sojourn in Italy) Goudsmit was given the task of bringing Uhlenbeck's knowledge of contemporary physics up to date.

It was in discussions between these two young men, still students, in 1925 that they introduced the notion of "spin". It may well be that by now the familiarity with this concept has blurred the unusual character of their proposal. It took a great deal of knowledge and even more courage to systematically explore and analyze the consequences of this idea. Although Ehrenfest continually encouraged them; the novelty and boldness of this step should certainly be kept in mind.

In 1926 both Uhlenbeck and Goudsmit were offered instructorships at the University of Michigan. There Goudsmit continued his work on the analysis of interpretation on atomic spectra. The field was summarized in an important text on atomic physics written together with Linus Pauling, *The Structure of Line Spectra* (McGraw-Hill, 1930).

Although Goudsmit had been extremely successful in the early phase of his scientific life it would be wrong to say that he was deliriously happy. His unhappiness and moodiness became more pronounced as time went on. There were many reasons for that: one was that (in part, due to his own researches) the field of physics in which he was most expert had reached a certain degree of completion; as such it was no longer in the center of interest. Although Goudsmit later worked in a number of different areas in physics, he never again felt as attuned and in control of a field, as he did in atomic spectroscopy. Although enormously talented Goudsmit often had the feeling that he did not possess enough intellectual technology to function effectively in physics. He had never been terribly interested in mathematics. (He used to say very frequently that he could only understand 2 by 2 matrices and nothing more. This is probably not true, but if it were he certainly made the absolute maximal use of the mathematics he controlled.) Goudsmit often expressed concern about his lack of mathematical ability. He felt that in order to advance in experimental physics a rather detailed understanding of accelerating machinery was essential — that knowledge he did not have either. This made it difficult to choose an effective new research area. There can be little doubt that the dramatic ending of Ehrenfest's life and the calamitous European political situation of the 1930's had a profound effect on Goudsmit. This affected everybody and in particular a sensitive person like Goudsmit. His scientific productivity obviously suffered and this in turn added to his general dissatisfaction with himself and with the world.

It cannot come as a surprise that when the Second World War broke out Goudsmit felt honour bound to take as active a part as possible. He first joined the MIT radiation laboratory and did some work on radar. Later he became the Chief Scientific Officer of the Alsos Project. This was a remarkable scientific intelligence mission; its purpose was to find the extent and status of German atomic weapons research. The results of his mission are written up in a book entitled *Alsos* (Sigma Books, London 1947) which unfortunately is out of print. It describes the mood and the atmosphere of wartime research in Germany. It is also intensely personal and written with great sensitivity — even pathos as when Goudsmit learned that his parents had been deported to an extermination camp. Only those who have suffered the trauma of tragedy and guilt which accompanies the total distruction of a family will fully appreciate the depression that is produced and only they will understand the extraordinarily painful struggle needed to keep going and in fact start anew.

After a short sojourn at Northwestern

University, 1946-1948, Goudsmit joined the Brookhaven National Laboratory in 1948. His interest and devotion to physics was as intense as ever. From 1952 to 1960 he was Chairman of the Brookhaven Physics Department; but equally important was his influence as Managing Editor of the *Physical Review*. He initiated the first letters journal, *Physical Review Letters*, still the most prestigous letter journal in physics.

Goudsmit received many honours, most of which were in connection with the discovery of spin. As expected he shared many of the honours with the codiscoverer of spin, George Uhlenbeck. They received the Research Corporation Science Award (1954), the Max Planck Medal of the German Physical Society (1965), the Karl T. Compton Award for Distinguished Statesmanship in Science, American Institute of Physics (1974) and the National Medal of Science (1977). There was also a commemorative meeting about spin and its discovery at the American Physical Society Annual Meeting in January 1976. Goudsmit and Uhlenbeck got their PhD degrees on the same day, 6 July, 1927. To express the appreciation and admiration of the Dutch scientists a special symposium was held to honour the 50th anniversary of their PhD degrees on 6 July 1977. It was a two day symposium with two highlights: the public highlight occurred when Goudsmit and Uhlenbeck received from the Dutch Government a very high decoration in recognition of their great accomplishments. This was not only a signal honour but a diplomatic feat as well, for such decorations can only be granted to Dutch citizens and Goudsmit and Uhlenbeck although born in Holland, were both naturalized American citizens.

But probably the more impressive and certainly the more touching celebration came when I walked with Goudsmit to the room where 50 years before he had taken his PhD examination. In that old room at the University of Leiden it is a tradition that after passing an examination the students write their names on a wall giving the date and type of examination. Goudsmit had bought a "magic marker" for the occasion; together we walked into the room where he had taken the examination (over the mild objection of the doorman). On the wall were hundreds of signatures. After some searching we found Goudsmit's signature for the right exam at the right time. Right above it Goudsmit wrote his signature with the black magic marker and added "Golden Jubilee of the PhD, July 6, 1977". After that we very quietly walked back. It was very clear to Goudsmit this was a significant and important event.

With the passing of Samuel Goudsmit the world of physics, indeed the whole world has lost a person of great sensitivity, understanding and talent. He was a man of fanatical honesty who detested circumlocution and vagueness. He was the exact opposite of pompous. His standards in physics and in life were extraordinarily high. He made corresponding demands on those around him — on his colleagues, on physics, and most certainly upon himself. That does not make for a terribly easy life, it does not make for a uniformly happy life, but it does mean that one can say with honesty and conviction — it mattered to the world that Samuel Goudsmit lived.

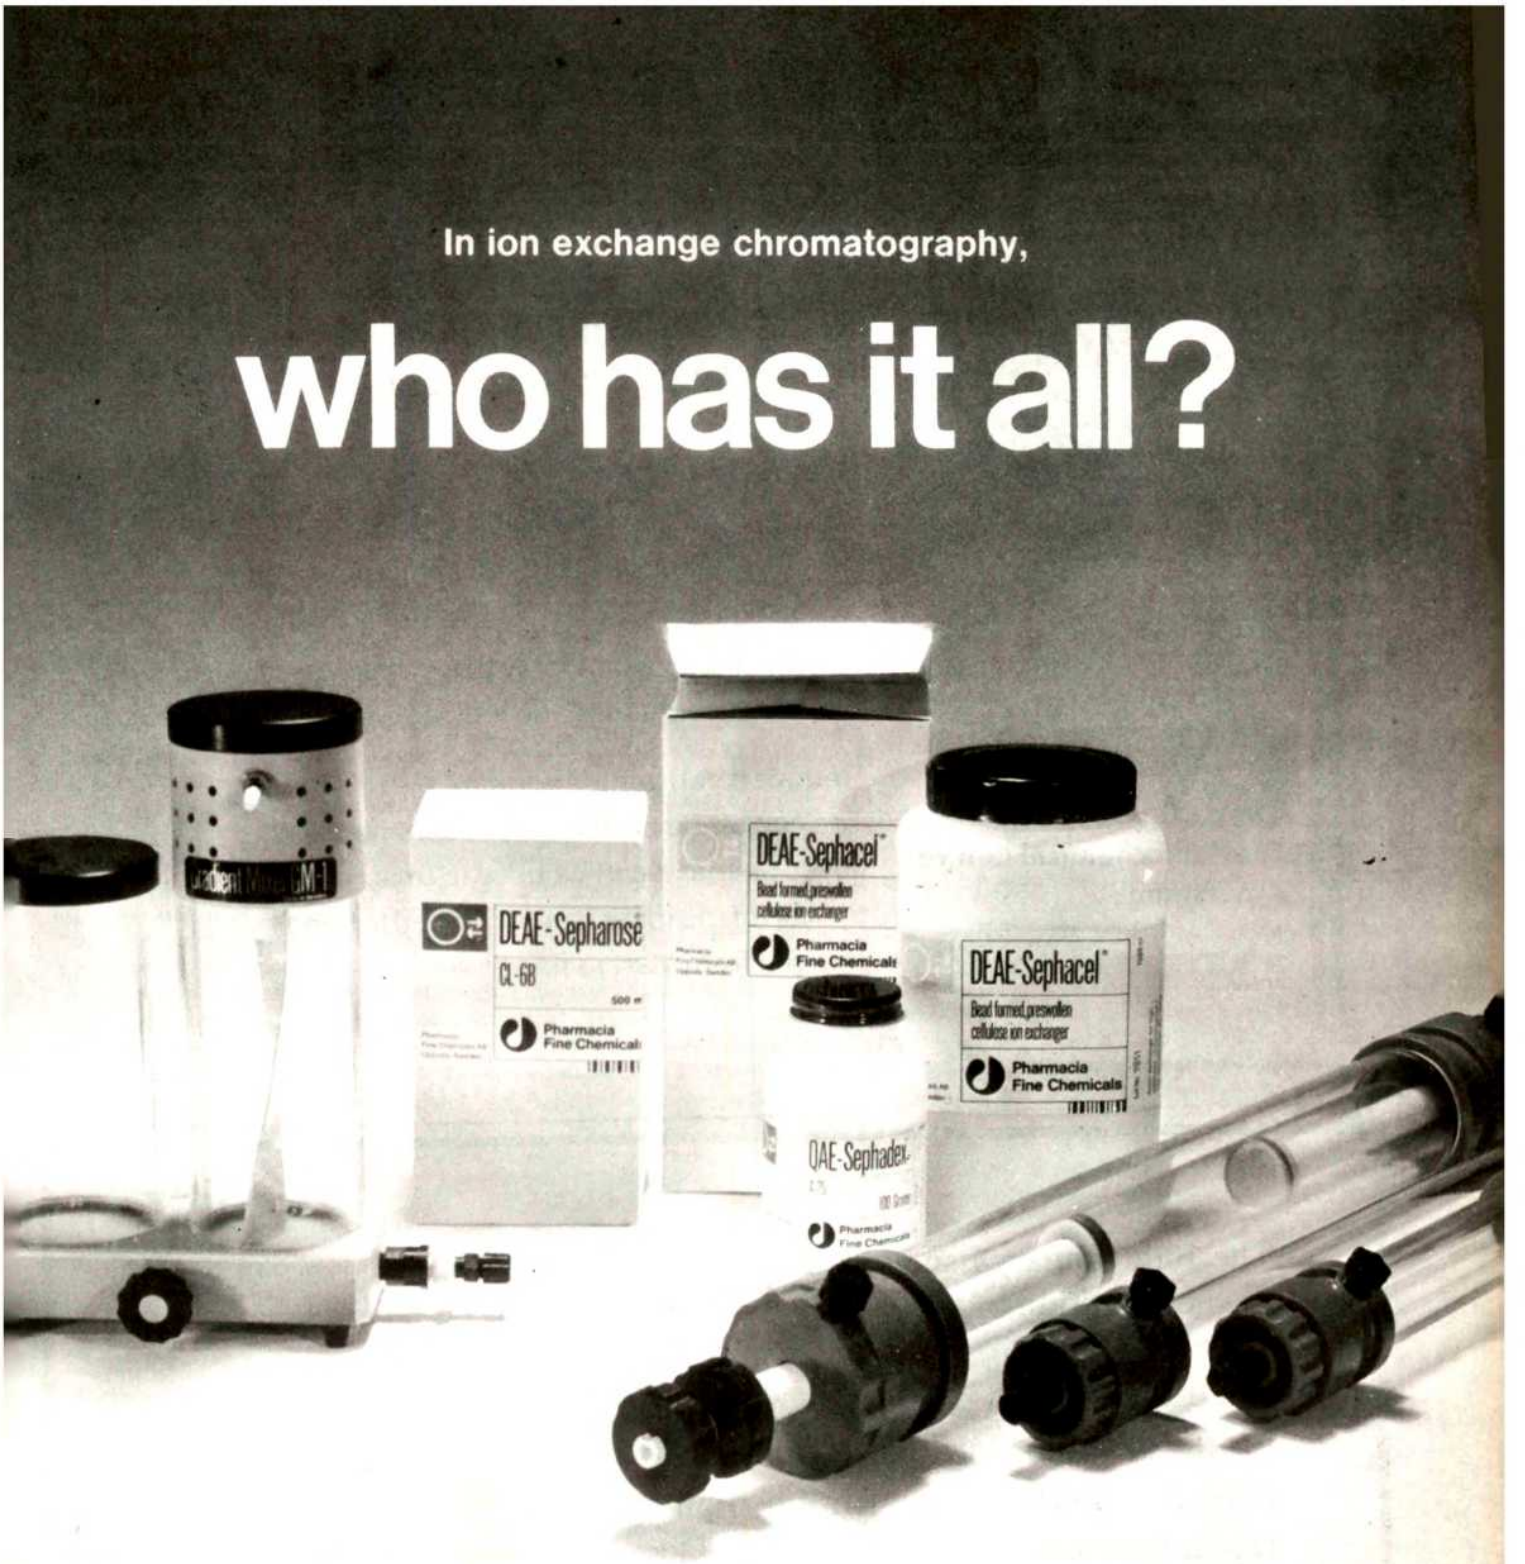
Max Dresden

R.N. Pryor

ROBERT NELSON PRYOR died of a heart attack in London on 14 July 1979, a few days short of his 58th birthday. He was at the peak of his powers and authority as a leading figure in the mining world.

Born in India while his father, a prominent mining engineer, was working in the Kolar Gold Fields, he was educated at Oundle and entered the Royal School of Mines, Imperial College, in 1939. After a year in which he played rugby for the RSM and rowed in the college first VIII, he joined the Royal Engineers and served in India and then with the Chindits in Burma. He finished the war with the rank of Captain, married the daughter of a New Zealand mining engineer, and returned to the College to obtain a first class honours degree in mining engineering in 1948.

His early career had a curious six-yearly cycle. Six years in the army and, when on graduation he went to Rio Tinto Mines in Spain, he spent six years in junior management before being made Chief Mining Engineer — a position which he occupied for six years. He then returned to the London office of Rio Tinto Zinc from where, for six years, he examined new mining projects including potash, lead-zinc, copper, nickel and pyrite in various parts of the world. In 1966 he was invited by the Spanish directors to become General Projects Manager of Rio Tinto Patiño, and in this post he supervised the launching of Cerro Colorado, the largest gold and copper mine in West Europe, and started construction of a new copper smelter and refinery at Huelva. His long and important contributions to Spanish mining did not go unrecognised, for in 1977 he became the first foreigner to receive honorary membership of the Asociación de Ingenieros de Minas de España.



In 1968 he was appointed Professor of Mining at Imperial College and brought back to his old school a wealth of experience in modern mining practice and management. As a teacher, his particular interests were in mineral production management, the design of large open-cast operations and in countering the environmental effects of mining past and future. He was much in demand as a consultant and, as his reputation grew, he became increasingly involved in recalcitrant problems, world-wide, as both technical adviser and arbiter. This heightened authority and experience was used to the benefit of his students — both undergraduate and postgraduate — and of his staff, many of whom were involved with him in the important, topical problems on which he was engaged.

In 1974 he became Head of the Department of Mineral Resources Engineering and, about the same time, began to assume the influence in professional engineering circles that culminated in his presidency of the Institution of Mining and Metallurgy and membership of the Executive Committee of the Council of Engineering Institutions. He did not spare himself, contributing in full to both organizations and serving as chairman and member of a large number of committees. Because he firmly believed that the engineering professions must come closer together, he was also an active Fellow of the Institution of Civil Engineers. He exemplified his conviction by organizing the Tunnelling '76 and Tunnelling '79 International Symposia — highly successful meetings which involved all three Institutions.

With his Presidential Address to the IMM, "Towards a Minerals Policy", delivered in June 1978, Bob Pryor embarked on what was to be his final project — to persuade the professions, industry and government of the need to take active, positive steps to ensure our vital mineral supplies. He followed this up with an informal meeting between government officials and representative mining and metallurgical experts in March 1979, and was one of the prime movers in arranging the National Symposium on the Availability of Strategic Minerals to be held in November of this year. His final contribution was an address entitled "Ensuring Access to Vital Supplies for Britain", which I read to the Parliamentary and Scientific Committee a few days after his death.

There was no badinage, no easy small-talk and certainly no flattery; but to his friends and those who enjoyed his confidence, he was the best of companions — warm and frank, interested and sympathetic, forthcoming and always sincere. Although his own standards were so high, he was in no way smug. He neither expected nor wanted others to share his views except by conviction. He was stubborn but open to reason. He was firm but generous. He had pride, but no conceit and, indeed, he was unduly diffident in some respects. He was humane and tolerant — up to a point — but he could not tolerate dishonesty. If, to these characteristics, you add intelligence, industry, an acute critical faculty, determination and a deep sense of responsibility, you have leadership. If you add courage and absolute integrity, you have a model for a complete professional engineer.

He is survived by his wife Patricia, three sons and a daughter. *M.G. Fleming*

Pharmacia has it all... ion exchangers, gradient mixer, columns

Since no single ion exchanger is best for all applications, Pharmacia now enables you to choose between three matrices: Sepharose® (cross - linked agarose), Sephadex® (cross - linked dextran), and now Sephacel® (cross - linked cellulose). Although they have different properties, they are all beaded to pack easily without generating fines.

Pharmacia also makes available the Gradient Mixer GM-1 for producing linear concentration gradients as well as reproducible pH gradients. Choose from a broad range of precisely engineered chromatographic columns for every application.

Pharmacia Fine Chemicals AB

Using Iodine-125?

New Microvial*

- reduced exposure
- reduced contamination risk

Reduced exposure

The new packaging consists of 2 parts

- An outer plastic container incorporating a steel shield
- An inner plastic vial with a conical glass insert containing the iodide solution

Reduced contamination risk

The cap of the plastic outer container is keyed so that it can be used to unscrew the cap of the inner vial — no need to handle this vial from start to finish.

Circle No. 10 on Reader Enquiry Card.

The 10th January issue of *Nature* will contain extensive coverage in the news section of the rapidly developing field of biotechnology.

Contributions will include:-
Professor Brian Hartley on applications of biotechnology;
Peter Newmark on the scientific origins;
David Dickson on patent issues raised by the new technology;
Robert Walgate on the problems that biotechnology raises for the academic community;
and Sheldon Krimsky and David Baltimore in a debate on the social and political questions.

announcements

Awards

The Council of the Royal Society has awarded the 1979 Royal Society Esso Award for the Conservation of Energy jointly to **Dr J.E. Harris** and **Dr V.W. Eldred**, for their contribution to the improvement in nuclear fuel utilisation in Magnox nuclear power stations.

Three US investigators, **Drs Solomon Snyder, Max Fink** and **Elliott Gershon**, shared the 1979 Anna Monika Foundation awards for contributions to the understanding of the biological bases of endogenous depression.

The prizewinners of the Feldberg Foundation awards for 1979 are **Dr E. Neher** and **Dr B. Sakmann, MPI** for Biophysical Chemistry, University of Göttingen and **Dr J.L. Gowans**, Secretary of the Medical Research Council and lately Director of the Medical Research Council Cellular Immunology Unit, Oxford.

The European Microwave Conference Prize of 1000 Swiss Francs for the best paper at the Brighton European Microwave Conference, has been won by **Ray Pengelly** of Plessey Research, Caswell.

Biochemical Society Awards: **Dr S.J. Singer** of the Department of Biology, University of California, San Diego, has been invited to deliver the Jubilee Lecture at the Biochemical Society Meeting in December. The Award includes the Harden Medal for 1980 for his distinguished work on the structure and function of membranes. Keilin Medal 1980 has been awarded to **Dr J. Kraut** of the Department of Biochemistry, University of California, San Diego. CIBA Medal and Prize 1979 has been awarded to **Dr J.B. Gurdons, FRS**, of the MRC Laboratory of Molecular Biology, Cambridge. Colworth Medal 1979 has been awarded to **Dr R.A. Laskey** of the MRC Laboratory of Molecular Biology, Cambridge.

Dr Heinz Karger Prize 1979 has been awarded to **Prof. Dr Louis Tobian** (USA). The Dr Heinz Karger Memorial Foundation invites the submission of papers on the following subjects: 1980 — An original research paper on 'Antibodies with Intrinsic Biological Activity'. 1981 — An original research paper on 'Intestinal Absorption of Peptides'. Applications to S Karger AG, Arnold-Böcklin-Strasse 25, CH-4011 Basle, Switzerland.

The 1979 Achievement Award for Scientific Instrument Development has been given to **Dr Harry Freeman**, of Harwell, for his work on laboratory scale heavy ion accelerators for isotope separation and ion implantation.

The British Association's trophy "to the sponsor of the British film released on or since 1 July 1977 which makes the most effective presentation to a non-specialist audience of a scientific or technological subject" was awarded to the University of Manchester/UMIST Audio-Visual Service for *Egyptian Mummies: an Investigation* and it was presented to producer Ken Wrench. Other certificates of merit went to British Airways, *Autoland*; The Central Electricity Generating Board for *Research for Power*; Dr J D Bromhall for *A Clone of Frogs*; and the Shell Company of Hong Kong Ltd for *Four Days in August*.

A new programme of research travel grants for Veterinary Scientists is being launched jointly by The Wellcome Trust of London and the Universities of Guelph and Saskatchewan in Canada.

The scheme is designed to enable Veterinary research workers in Britain/Ireland and Canada to visit each other's country to study, to learn a new research technique, and to work with colleagues with similar interests. The visits are expected to be of relatively short duration, up to three months, and the research grants will meet the costs of travel and subsistence.

Enquiries about visits to Canada from workers in Britain and Ireland should be addressed to The Wellcome Trust, 1 Park Square West, London NW1, UK. Enquiries about visits to Britain and Ireland from workers in Canada should be addressed either to The Dean, College of Graduate Studies and Research, University of Saskatchewan, or to The Dean, Ontario Veterinary College, University of Guelph.

The Directors of the Teylor Foundation and the members of Teyler's Second Society, Haarlem, The Netherlands, announce the following topic for competition for the Teyler Medal: A treatise on the mechanisms which, during morphogenesis, cause the development of genetically determined shapes of parts of organisms (such as, feathery antennae of insects, Grecian nose, and comparable structural parts of plants or micro-organisms). Entries to: The Directors of Teyler's Foundation, Damstraat 21, 2011 HA Haarlem, The Netherlands.

Three hundred National Engineering Scholarships, each worth £500 a year tax free, will be open to high calibre students starting engineering degree courses at universities, polytechnics and other higher education establishments in the academic year 1980–81. The joint Government-industry scholarship scheme is designed to encourage students of high ability to take first degree courses in engineering which tie in with a career in the manufacturing industry. Copies of the pamphlets and application forms are available from Room 7/19, Department of Education and Science, Elizabeth House, York Road, London SE1, UK.

The Advancement of Application of Agriculture and Food Chemistry Award is administered by the Division of Agricultural and Food Chemistry of the ACS and sponsored by International Flavors and Fragrances, Inc. It aims to recognise and encourage outstanding contribution(s) to pure and/or applied agricultural and food chemistry. Nomination forms from the Chairman of the Canvassing Committee, Dr Marshall Phillips, National Animal Disease Center,USDA, PO box 70, Ames, Iowa 50010.

Some hospital posts for junior doctors in Paris and Lyon are reserved specifically for foreigners and will be available from October 1980. Applicants should be at least two years post-registration, under 35 years old and speak fluent French. The posts are of one year duration. Further information from the "Service Scientifique", Ambassade de France, 41 Parkside, Knightsbrige, London SW1, UK.

Under reciprocal agreements with the Centre Nationale de la Recherche Scientifique (CNRS) and the Deutsche Forshungsgemeinschaft (DFG) the Social Science Research Council is able to recommend a number of British candidates for research visits to universities and research establishments in France or the Federal Republic of Germany during 1980/81. Candidacy is limited to social scientists with a working knowledge of French or German on the staff of universities, polytechniques, institutes of further/higher education, and independent research institutes. Further details from SSRC French/German Programmes, Research Initiatives Division, 1 Temple Avenue, London EC4, UK. Quote reference FP7 for France or DP7 for Germany.

Nominations are invited for the 1980 Rosenstiel Award in Oceanographic Science. The award recognises outstanding achievement and distinction in oceanographic science, including relevant aspects of ocean engineering where significant new principles are concerned, and aspects of atmospheric science with important implications for understanding of oceanic processes. The award is supported by the Rosenstiel Foundation through the Rosenstiel School of Marine and Atmospheric Science of the University of Miami. Applications to Dr Richard W Eppley, Institute of Marine Resources, A-018, University of California, San Diego, La Jolla, California 92093.

Meetings

9-10 January, **Medical Applications of Electroanalytical Chemistry,** Newcastle upon Tyne (Dr J.V. Dobson, The Electrochemical Research Laboratories, School of Chemistry, University of Newcastle upon Tyne, UK).

30 January, **Reliability of Semiconductor Components,** London (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

30 January, **Geology and Health,** London (Geological Society of London, Burlington House, London W1, UK).

4-7 February, **SYMPHONE,** Berlin CNES, 18 Ave Edouard-Belin, 31055 Toulouse Cedex, France).

17-21 March, **International Conference on Human Herpesviruses,** Atlanta (Tom Sellers, 107 WMCAB, Emory University, Atlanta Georgia 30322).

19 March, **Animal models for the study of Human Nutrition,** London (The Nutrition Society, Chandos House, 2 Queen Anne St, London W1, UK).

9-12 April, **3rd Annual Conference of the Portuguese Chemical Society,** Coimbra (Secretariado do 3°. Encontro Nacional de Química, Departamento de Química, Faculdade de Ciencias e Tecnologia, 300 Coimbra, Portugal).

10-12 April, **Life in the Precambrian,** Leicester (Dr T.D. Ford, Dept of Geology, The University, Leicester, UK).

13-18 April, **Introduction to Toxicology,** Loughborough (Dr G.E. Chivers, University of Technology, Loughborough, Leicestershire, UK).

14-17 April, **Low Energy Ion Beams,** Bath (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

14-18 April, **Postgraduate School on Aspects of Toxicological Testing Methods,** London (R.E. Marshall, School Secretary, Dept of Pharmaceutical Sciences, The Pharmaceutical Society of Great Britain, 1 Lambeth St, London SE1, UK).

14-18 April, **European Rocket and Balloon Programmes,** Bournemouth (Programme Advisory Committee on the ESRANGE Special Project, European Space Agency, 8-10 rue Mario Nikis, 75738 Paris Cedex 15, France).

15-17 April, **Waste-to-Energy,** Cincinnati (Ruth Anne Gibson, Battelle's Columbus Laboratories, 505 King Ave, Columbus, Ohio 43201).

23-30 April, **Remote Sensing of the Environment,** San José (J.J. Cook, Environmental Research Institute of Michigan, PO Box 8618, Ann Arbor, Michigan 48107).

24-25 April, **Grass and Grass Products in the Eighties,** Ayr (Nutrition Society, Chandos House, 2 Queen Anne St, London W1, UK).

25 April, **Aeration of Waste Water,** London (BHRA Fluid Engineering, Cranfield, Bedford, UK).

27 April — 3 May, **EUCHEM Confrence on Stereochemistry,** Burgenstock (Prof. J.D. Dunitz, Laboratorium für Organische Chemie, ETHZ, Universitatsstr. 16, CH-8092 Zürich, Switzerland).

28-30 April, **Economic Effects of Space and other Advanced Technologies,** Strasbourg (European Space Agency, 8-10 rue Mario Nikis, 75738 Paris, Cedex 15, France).

29-30 April, **Programming Microprocessors for Industrial Measurement and Control,** London (Carole Meads, Sira Institute Ltd, Soth Hill, Chislehurst, Kent, UK).

newly on the market

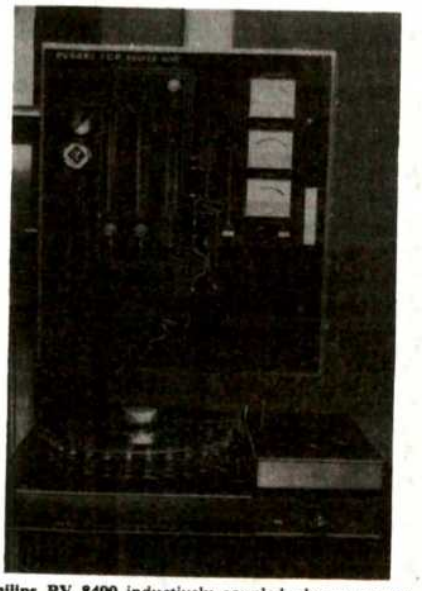
These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. For more details use the Reader Enquiry Card bound inside the journal.

X-Ray fluorescence analyser. Jobin-Yvon. The Model JY 410 Portarix from Jobin-Yvon is a portable radio isotope X-ray fluorescence analyser designed for elemental analysis of ores, steel alloys, cement and other materials, identification of foreign substances in materials and thickness measurements of coated metals both in industry and laboratories. The Portarix is a compact, light-weight and robust instrument which can be carried by one man from place to place in the field.
Circle No. 140 on Reader Enquiry Card.

Nucleonics Accessories brochure. Packard announce a new brochure giving details on their extensive range of scintillation cocktails, reagents, vials and reference materials for liquid scintillation and automatic γ-counting techniques. The brochure contains details on over 250 separate items of scintillation counting consumables.
Circle No. 141 on Reader Enquiry Card.

γ-Counters. The Philips PW 4800 series of γ-counters combine latest state-of-the-art technology with maximum reliability and minimum cost to the user. Due to the incorporation of microprocessors, performance is of a very high order. Standard features include background subtract and automatic compensation for long-term photomultiplier gain drift, using a background standard. The extent of amplification adjustment is given, with an indication if beyond set limits. Data are produced as c.p.m., % c.p.m., normalised c.p.m., and, for radioimmunoassay, % bound. With the optional integral calculator, conversion of count into disintegrations per min is automatic, after calibration with a standard. For dual label programs a similar procedure gives automatic correction for spillover between low and high energy windows.
Circle No. 142 on Reader Enquiry Card.

The Philips PW 4800 automatic γ-counter



Flashlamp system. Edinburgh Instruments. The EI-199F coaxial flashlamp system is a versatile pulsed light source designed for a wide range of applications including fluorescence, phosphorescence, photochemistry, laser simulation and fibre optic cable and detector testing. The complete system includes the thyratron gated flashlamp, high voltage power supply and triggering unit, and monitoring photomultiplier and power supply. Variable pulse widths to below 1 ns at continuously tunable repetition rates from 1 Hz to 100 Hz can be obtained. Stability monitoring of every light pulse is included, and the flashlamp's all-metal coaxial construction eliminates rf interference problems.
Circle No. 143 on Reader Enquiry Card.

Liquid scintillation counters. The Philips liquid scintillation counters, series PW 4700, have extensive measurement correction and data processing abilities, improved reliability and reduced prices. Use of microprocessors provides four measurement correction functions, which together with a random coincidence monitor, give 10 combinations. The extent of quenching for single labelled samples can be measured using either the sample channels ratio or by the external standard channels ratio. The latter method is applicable to both single and dual label samples.
Circle No. 144 on Reader Enquiry Card.

Energy-dispersive X-ray spectrometry system. Philips. Fast, simultaneous multi-element analysis capability at modest cost, without the limitation of a fixed number of measuring channels, is possible using the Philips PV 9500 energy-dispersive X-ray spectrometry system. The system permits identification and determination of all elements from sodium to uranium in solids, powders and liquids. Measurements are possible from major constituent levels down to a few p.p.m. Addition of a specially developed spectrometer unit to the recently introduced PV 9100 multi-channel analyser has produced a compact, self-contained system that is easily installed in any location. The caster-mounted spectrometer and analyser consoles can be independently sited to suit available space. No mains services other than electrical connection are required.
Circle No. 145 on Reader Enquiry Card.

Workgloves. DuPont. Parabest 'Premier' gloves from DuPont are made from Kevlar 29 fabric, a material with outstanding properties of cut, puncture and heat resistance. In addition, they offer excellent thermal insulation, and so can be used safely and comfortably in higher heat conditions and for longer working periods than is possible with leather or asbestos.
Circle No. 146 on Reader Enquiry Card.

Polarographic stand. Bruker. The Model E-2 polarographic stand from Bruker eliminates the classical problem of polarography where too many wires, tubes and electrodes have to be brought into a small cell. In this new design of stand, electrical and gas connections are short and tidy; the mercury or glassy carbon working electrode is easily inserted or removed and a stirrer is incorporated. The result is a tidy and convenient experimental set up.
Circle No. 147 on Reader Enquiry Card.

Philips PV 8490 inductively coupled plasma source unit, together with optional sample changer. This combination permits unattended batch analysis of liquids and virtually any samples in aqueous or organic solution.
Circle No. 148 on Reader Enquiry Card.

Vacuum spectrometer. A new version of the Philips PV 8350 compact vacuum optical emission spectrometer offers an extended range of excitation possibilities, including inductively coupled plasma (ICP) and glow discharge. This 1-m spectrometer permits simultaneous measurement of up to 40 elements, and is available in a variety of configurations. It may be delivered with a single excitation source, but for more varied programmes, more than one source unit can be fitted.

FROM THE MACMILLAN PRESS

New Titles

THE ECOLOGY AND CONSERVATION OF LARGE AFRICAN MAMMALS
S. K. Eltringham, with a foreword by Sir Peter Scott CBE DSC
"The flora and fauna of Africa are one of the greatest wonders of the world. Mankind has a responsibility to assure their continued existence and I believe this book will significantly help to do just that." *Sir Peter Scott*
A scholarly but readable account, summarising the findings of the many wildlife research stations at work in Africa.
£15.00 0 333 23580

EVOLUTIONARY ECOLOGY
Bernard Stonehouse and Christopher Perrins
Available for the first time in paperback
"This is a book which every keen amateur naturalist should read." *Oxford Mail.*
21 essays in honour of Dr. David Lack. They cover four main areas; Population regulation and Function of territory, Feeding adaptions and Ecological segregation, Breeding adaptions and Reproductive rates, and Behaviour, Adaption and Taxonomic relationships.
£5.95 0 333 281626

DECISION MAKING FOR ENERGY FUTURES: A case study of the Windscale inquiry.
D. W. Pearce et al.
Who decides the Scientists and Technicians or the Politicians?
Using the application by BNFL to set up an oxide fuel reprocessing plant at Windscale the authors of this study examine the ways in which our energy future is being decided.
The come to some controversial conclusions. They believe that national issues are being removed from democratic control as a result of their deliberation outside parliament and within the bureaucratic planning machinery.
£10.00 0 333 274385

A DICTIONARY OF THE ENVIRONMENT
Michael Allaby
Now in PAPERMAC
DEFINES SOME 6,000 WORDS AND PHRASES.
"The rapidly evolving vocabulary of any one of the life or earth sciences ... can be bewildering both to the lay reader and the specialist trained in another field. Michael Allaby's *A Dictonary of the Environment* attempts to cover them all, and to appeal to lay reader and scientists alike." *Richard Clarke-Nature*
£3.95 0 333 274490

To be published in February 1980

GROWTH WITHOUT ECODISASTERS
N. Polunin
The environment is under attack. Its resources have been plundered to sustain industrial and technological growth. If growth is to continue and man is to live in a pleasant and healthy environment its use must be carefully planned and controlled.
The 18 chapters in this book are based on the keynote papers, and the discussions that followed them, presented at the 2nd International Conference on Environment Future held at Reyjavik in 1977. Papers, each of which was presented by a specialist in the field, range from Fresh waters and their biota to Life-style alternatives and the Ethics of biospheral survival.

THE CHAIN STRAIGHTENERS: FRUITFUL INNOVATION – THE DISCOVERY OF LINEAR AND STEREO-REGULAR POLYMERS
Frank M McMillan
The story of the remarkable burst of scientific discovery and technological innovation that gave science mastery over the 3-dimensional structure of high polymers and the world its most useful group of plastics and synthetic rubbers. A story surrounded by controversy, where science meets big business and powerful personalities clash. This will undermine many of the conventional views of scientific innovation.
£9.00 0 333 259297

FROM DNA TO PROTEIN: The Transfer of Genetic Information
Maria Szekely
This is the first textbook which discusses gene structure on the basis of recent discoveries of overlapping and split genes and which gives a consistent image of the ways in which genetic information can be encoded into the genetic material and how it can be transfered to other materials.
A perfectly up-to-date account of our present knowledge of the structure and expression of genes in prokaryotic and eukaryotic organisms and the only available text showing the correlation between the structure and function of nucleic acids.

Recent scientific and technical books

Applied biology

CAMERINI-DAVALOS, Rafael A., and HANOVER, Bernard (ed.). Treatment of Early Diabetes. (Advances in Experimental Medicine and Biology, Vol. 119.) Pp.xvi + 532. ISBN-0-306-40194-0. (New York and London: Plenum Press, 1979.) $49.50.

COHEN, Stanley, PICK, Edgar and OPPENHEIM, Joost J. (ed.). Biology of the Lymphokines. Pp.xvi + 626. ISBN-0-12-178250-6. (New York and London: Academic Press, 1979.) $42.50.

DE THE, G., HENLE, W., and RAPP, F. (ed.). Oncogenesis and Herpesviruses III. Part 2: Cell-Virus Interactions, Host Response to Herpesvirus Infection and Associated Tumours, Role of Co-Factors. (Proceedings of the Third International Symposium on Oncogenesis and Herpesviruses, held in Cambridge, Mass., USA, 25-29 July 1977). (World Health Organization. International Agency for Research on Cancer.) Pp.xv + 583-1102½ (Lyon, France: International Agency for Research on Cancer, 1978. Distributed by WHO, Geneva; London, HMSO.).

DRAPER, Harold H. (ed.). Advances in Nutritional Research, Vol.2. Pp.xiii + 250. ISBN-0-306-40213-0. (New York and London: Plenum Press, 1979.) $27.50.

EHRLICH, Yigal H., VOLAVKA, Jan, DAVIS, Leonard G., and BRUNNGRABER, Eric G. (edited by). Modulators, Mediators, and Specifiers in Brain Function: Interactions of Neuropeptides, Cyclic Nucleotides, and Phosphoproteins in Mechanisms Underlying Neuronal Activity, Behavior, and Neuropsychiatric Disorders. (Advances in Experimental Medicine and Biology, Vol. 116.) PP.xv + 327. ISBN-0-306-40173-8. (New York and London: Plenum Press, 1979.) $35.

ELLIS, G.P., and WEST, G.B. (ed.). Progress in Medicinal Chemistry, 16. Pp.x + 292. ISBN-0-7204-0667-6. (Amsterdam, New York and Oxford: North-Holland Publishing Company, 1979.) Dfl. 130; $63.50.

EPSTEIN, M.A., and ACHONG, B.G. (ed.). The Epstein-Barr Virus. Pp.xvi + 459. ISBN-3-540-09272-2. (Berlin and New York: Springer-Verlag, 1979.)

FIELD, Tiffany Martini (ed.). SOSTEK, Anuta Miller. Infants Born at Risk: Behavior and Development. Pp.498. ISBN-0-89335-057-5. (New York and London: SP Medical and Scientific Books, 1979.) £20.25.

FUJII, Setsuro, MORIYA, Hiroshi, and SUZUKI, Tomoji (ed.). Kinins — II: Biochemistry, Pathophysiology, and Clinical Aspects. (Advances in Experimental Medicine and Biology, Vol. 120A.) Pp.xii + 610. ISBN-0-306-40196-7 (Part A). (New York and London: Plenum Press, 1979.) $59.50.

GILL, G.N. (ed.). Pharmacology of Adrenal Cortical Hormones. (International Encyclopedia of Pharmacology and Therapeutics.) Pp.xi + 243. ISBN-0-08-019619-5. (Oxford and New York: Pergamon Press, 1979.) £22; $40.

GREGORY, John D., and JEANLOZ, Roger W. (ed.). Glycoconjugate Research, Vol.2. (Proceedings of the Fourth International Symposium on Glycoconjugates.) Pp.xx + 575-1103. ISBN-0-12-301302-X. (New York and London: Academic Press, 1979.) $29.50.

HINGLEY, Marjorie. Fieldwork Projects in Biology. Pp.170. ISBN-0-7137-0964-2. (Poole, Dorset: Blandford Press, 1979) £4.95 net.

IDAIKKADAR, N.M. Agricultural Statistics: a Handbook for Developing Countries. (Pergamon International Library of Science, Technology, Engineering and Social Studies.) Po.xii + 139. ISBN-0-08-023387-2. (Oxford and New York: Pergamon Press, 1979.) Hard £10; Flexi £4.50.

INGELS Jr., Neil B. (ed.). The Molecular Basis of Force Development in Muscle. Pp.vii + 162. ISBN-0-933612-00-1. (Palo Alto, CA.: Palo Alto Research Foundation, 1979.

JELLIFFE, Derrick B., and JELLIFFE, E.F. Patrice (ed.). Nutrition and Growth. (Human Nutrition: a Comprehensive Treatise, Vol. 2) Pp.xx + 452. ISBN-0-306-40128-2. (New York and London: Plenum Press, 1979.) $37.50.

LAJTHA, L.G. (guest editor). Cellular Dynamics of Haemopoiesis. (Clinics in Haematology, Vol. 8, No. 2, June 1979.) Pp.viii + 219-528. (London, Philadelphia and Toronto: W.B. Saunders Company, 1979.) £8.25.

LEPOW, Irwin H., and CROZIER, Ruth (ed.). Vasectomy: Immunologic and Pathophysiologic Effects in Animals and Man. (Proceedings of a Workshop held at Airlie, Virginia, April 24-27, 1978.) Pp.xiv + 600. ISBN-0-12-444150-5. (New York and London: Academic Press, Publishers, 1979.) $34.

LEAVITT, Wendell W., and CLARK, James H. (ed.). Steroid Hormone Receptor Systems. (Advances in Experimental Medicine and Biology, Vol. 117.) Pp.ix + 489. ISBN-0-306-40182-7. (New York and London: Plenum Press, 1979.) $45.

LONG-TERM HAZARDS FROM ENVIRONMENTAL CHEMICALS. (A Royal Society Discussion organised by Sir Richard Doll, F.R.S., and A.E.M. McLean for the Royal Society's Study Group on Long-Term Toxic Effects, held on 13 and 14 December 1977.) Pp.vi + 197. ISBN-0-85403-110-3. (London: The Royal Society, 1979.) UK £8.75; Overseas £9.05.

McGUIRE, William L. (ed.). Breast Cancer: Advances in Research and Treatment. Vol. 3: Current Topics. Pp.xv + 271. ISBN-0-306-40228-9(v.3). (New York and London: Plenum Medical Book Company, 1979.) $39.50.

MADDRELL, Simon H.P., and NORDMANN, Jean J. Neurosecretion. (Tertiary Level Biology.) Pp.x + 173. ISBN-0-216-90758-6. (Glasgow and London: Blackie and Son, Ltd., 1979.) £8.25.

MANDAL, Anil K. Electron Microscopy of the Kidney In Renal Disease and Hypertension. Pp.xx + 452. ISBN-0306-40110-X. (New York and London: Plenum Medical Book Company, 1979.) $32.50.

MARAMOROSCH, Karl, and HARRIS, Kerry F. (ed.). Leafhopper Vectors and Plant Disease Agents. Pp.xvi + 654. ISBN-0-12-470280-5. (New York and London: Academic Press, 1979. $39.

MELNICK, Joseph L. (ed.). Progress in Medical Virology, Vol. 25. Pp.x + 179. ISBN-3-8055-2978-3. (Basel, London and New York: S. Karger, 1979.) Sfr.89; DM107; $53.50.

MESSEGUE, Maurice. Health Secrets of Plants and Herbs. Pp.336 + 32 plates. ISBN-0-00-216529-5. (London and Glasgow: William Collins Sons and Co., Ltd., 1979.) £7.95.

MEYER, J.S., LECHNER, H., and REIVICH, M. (ed.). In association with OTT, E.O., and ARANIBAR, A. Cerebral Vascular Disease 2. (Proceedings of the 9th International Salzburg Conference, September 27-30, 1978.) Pp.383. ISBN-90-219-0378-4. (Amsterdam and Oxford: Excerpta Medica, 1979.) Dfl. 140; $68.25.

MULLER-RUCHHOLTZ, Wolfgang, and MULLER-HERMELINK, Hans Konrad (ed.). Function and Structure of the Immune System. (Advances in Experimental Medicine and Biology, Vol. 114.) Pp.xxi + 850. ISBN-0-306-40158-4. (New York and London: Plenum Press, 1979.) $75.

MYRIANTHOPOULOS, N.C., and BERGSMA, D. (ed.). PAUL, N.W. (associate editor). DICKMAN, F. (assistant editor). Recent Advances in the Developmental Biology of Central Nervous System Malformations. (The National Foundation — March of Dimes. Birth Defects: Original Article Series, Volume XV, No. 3, 1979.) Pp.xiv + 139. ISBN-0-8451-1026-8. (New York: Alan R. Liss, Inc., 1979.) $16.

OTSUKA, Masonori, and HALL, Zach W. (ed.). Neurobiology of Chemical Transmission. (The First Taniguchi Symposium of Brain Sciences.) Pp.x + 326. ISBN-0-471-03974-8. (New York and Chichester: John Wiley and Sons, 1979.) £15.50.

PEPER, Erik, ANCOLI, Sonia, and QUINN, Michele (ed.). Mind/Body Integration: Essential Readings in Biofeedback. Pp.xx + 586. ISBN-0-306-40102-9. (New York and London: Plenum Press, 1979.) $25.

PEPPLER, H.J., and PERLMAN, D. (ed.). Microbial Technology Vol. 1: Microbial Processes. Pp.xvi + 552. ISBN-0-12-551501-4. $47.50. Vol.2: Fermentation Technology. Pp.xviii + 536. ISBN-0-12-551502-2 (v.2). $44. Second edition. (New York and London: Academic Press, 1979.)

PETRICCIANI, John C., HOPPS, Hope E., and CHAPPLE, Paul J (ed.). Cell Substrates: Their Use on the Production of Vaccines and Other Biologicals. (Advances in Experimental Medicine and Biology. Vol. 118.) Pp.viii + 220. ISBN-0-306-40189-3. (New York and London: Plenum Press, 1979.) $29.50.

PORTER, Ian H., and HOOK, Ernest B. (ed.). Service and Education in Medical Genetics. (Proceedings of the Seventh Annual New York State Health Department Birth Defects Symposium.) Pp.xiv + 425. ISBN-0-12-562650-9. (New York and London: Academic Press, 1979.) $24.

QUASTEL, Michael R. (ed.). Cell Biology and Immunology of Leukocyte Function. (Proceedings of the Twelfth International Leukocyte Culture Conference, held at the Ben Gurion University of the Negev, Beer Sheva, Israel, June 25-30, 1978.) Pp.xxix + 959. ISBN-0-12-569650-4. (New York and London: Academic Press, 1979.) $45.

RAJKI, Sandor (ed.). Workshop on Food and Nutrition. (Proceedings of a Workshop on Agricultural Potentiality Directed by Nutritional Needs, June 5-9, 1978, Martonvásár.) Pp.237. ISBN-963-05-1991-7. (Budapest: Akadémiai Kiadó, 1979.) $21.

RAY, William J., RACZYNSKI, James, ROGERS, Todd, and KIMBALL, William H. Evaluation of Clinical Biofeedback. Pp.xi + 330. ISBN-0-306-40206-9. (New York and London: Plenum Press, 1979.) $25.

ROSENBERG, Roger N. (ed.). The Treatment of Neurological Diseases. Pp.613. ISBN-0-89335-062-1. (New York and London: SP Medical and Scientific Books, 1979.) £31.50.

RUSSELL, A.D., and FULLER, R. (ed.). Cold Tolerant Microbes in Spoilage and the Environment. (The Society for Applied Bacteriology Technical Series, No. 13). Pp.xii + 169. ISBN-0-12-603750-7. (London and New York: Academic Press, 1979.) £9.80; '£21.

SCOTT, Tom K. (ed.). Plant Regulation and World Agriculture. (NATO Advances Study Institutes Series. Series A: Life Sciences, Vol. 22.) Pp.xi + 575. ISBN-0-306-40180-0. (New York and London: Plenum Press, 1979. Published in cooperation with NATO Scientific Affairs Division.) $47.50.

SEEMANN, J., CHIRKOV, Y.I., LOMAS, J., and PRIMAULT, B. Agrometeorology. Pp.vi + 324, ISBN-3-540-09331-1. (Berlin and New York: Springer-Verlag, 1979.) DM98; $53.90.

SELA, Michael (ed.). The Antigens, Vol.5. Pp.xiii + 410. ISBN-0-12-635505-3. (New York and London: Academic Press, 1979.) $35.

SHEETS, T.J., and PIMENTEL, David (ed.). Pesticides: Contemporary Roles in Agriculture, Health and Environment. Pp.xii + 186. (Clifton, NJ.: Humana Press, 1979.) $19.50.

SIMMONS, David J., and KUNIN, Arthur S. (ed.). Skeletal Research; An Experimental Approach. Pp.xvi + 612. ISBN-0-12-644150-2. (New York and London: Academic Press, 1979.) $55.

STEWARD, David J., and the Staff of the Department of Anaesthesia, The Hospital for Sick Children, Toronto. Manual of Peaidtric Anesthesia. With the editorial assistance of U.F. Matthews. Pp.xii + 305. ISBN-0-443-08019-4. (New York, Edinburgh and London: Churchill Livingstone, 1979.) £9.

THALEN, D.C.P. Ecology and Utilization of Desert Shrub Rangelands in Iraq. Pp.viii + 448. ISBN-90-6193-593-8. (The Hague: Dr. W. Junk B.V., Publishers, 1979.) Dutch Guilders 150; YS$78.95.

THOMSON, J.R. An Introduction to Seed Technology. Pp.viii + 252. ISBN-0-249-44155-1. (Glasgow and London: Leonard Hill, a member of the Blackie Group, 1979.) £14.95.

TREVINO-BECERRA, A., and BOEN, Fred S.T. (ed.). Today's Art of Peritoneal Dialysis. (Contributions to Nephrology, Vol.17.) Pp.x + 150. ISBN-3-8055-3006-4. (Basel, London and New York: S. Karger, 1979.) SFr. 75; DM 90; $45.

TULLY, J.G., and WHITCOMB, R.F. (ed.). The Mycoplasmas. Vol. 2: Human and Animal Mycoplasmas. Pp.xiv + 509. ISBN-0-12-078402-5. (New York and London: Academic Press, 1979.) $42.

VICKERY, Margaret L., and VICKERY, Brian. Plant Products of Tropical Africa. (Macmillan Tropical Agriculture, Horticulture and Applied Ecology Series.) Pp.xi + 116. ISBN-0-333-24802-3. (London and Basingstoke: The Macmillan Press, Ltd., 1979.) Hardcover £10.95; Paperback £4.95.

WEINSTEIN, Louis, and FIELDS, Bernard N. (ed.). Seminars in Infectious Disease, Vol. 2. Pp.v + 346. ISBN-0-913258-61.X (New York: Stratton Intercontinental Medical Book Corp., 1979.) $32.50.

WURTMAN, Richard J., and WURTMAN, Judith J. (ed.). Nutrition and the Brain. Vol.4: Toxic Effects of Food Constituents on the Brain. Pp.x + 222. ISBN-0-89004-246-2. (New York: Raven Press, 1979.) $23.

ZBINDEN, G., and GROSS, F. (section editors). Pharmacological Methods in Toxicology. (International Encyclopedia of Pharmacology and Therapeutics, Section 102.) Pp.xi + 612. ISBN-0-08-024900-0. (Oxford and New York: Pergamon Press, 1979.) £57.50.

Psychology

AIELLO, John R., and BAUM, Andrew (ed.). Residential Crowding and Design. Pp.xv + 252. ISBN-0-306-40205-X. (New York and London: Plenum Press, 1979.) $24.50.

BALLOU, Judith W. The Psychology of Pregnancy: Reconciliation and Resolution. Pp.vii + 143. ISBN-0-669-02377-9. (Lexington, Mass. and Toronto: Lexington Books; Farnborough, Hants: Lexington Books, Teakfield Ltd., 1978.) £9.50.

BALTES, Paul B., and BRIM, Jr., Orville G. (ed.). Life-Span Development and Behavior, Vol.2. Pp.xiii + 348. ISBN-0-12-431802-9. (New York and London: Academic Press, $23.

BATES, Elizabeth. With the collaboration of Laura Benigni, *et al.* The Emergence of Symbols: Cognition and Communication in Infancy. (Language, Thought, and Culture: Advances in the Study of Cognition.) Pp.xvi + 387. ISBN-0-12-081540-0. (New York and London: Academic Press, 1979.) $29.50.

BRAIN, Paul F. Hormones and Aggression, Vol.2. (Annual Research Reviews: Psychology and Psychiatry.) Pp.183. ISBN-0-443-01913-4. (Montreal: Eden Press, Inc.; St. Albans, Vermont: Eden Medical Research, Inc.; Edinburgh: Churchill Livingstone, Medical Division of Longman Group, Ltd., 1979.) £12.75.

COHEN, David B. Sleep and Dreaming: Origins, Nature and Functions. (International Series in Experimental Psychology, Vol. 23.) Pp.xii + 315. ISBN-0-08-021467-3. (Oxford and New York: Pergamon Press, 1979.) £16.25.

DICKINSON, Anthony, and BOAKES, Robert A. (ed.). Mechanisms of Learning and Motivation. (A Memorial Volume to Jerzy Konorski.) Pp.xiii + 468. ISBN-0-470-26567-1. (Hillsdale, NJ.: Lawrence Erlbaum Associates, Publishers, 1979. Distributed by the Halsted Press Division of John Riley and Sons, New York and Chichester.) $18.25.

HAMILTON, Vernon, and WARBURTON, David M. (ed.). Human Stress and Cognition: An Information Processing Approach. Pp.xi + 502. ISBN-0-471-27572-7. (Chichester and New York: John Wiley and Sons, 1979.) £19.50.

LIBEN, Lynn S. (ed.). Deaf Children: Developmental Perspectives. (Developmental Psychology Series.) P p.xv + 246. ISBN-0-12-447950-2. (New York and London: Academic Press, 1978.) $17.59.

McKELLAR, Peter. Mindsplit: The Psychology of Multiple Personality and the Dissociated Self. Pp.188. ISBN-0-460-04348-X. (London, Melbourne and Toronto: J.M. Dent and Sons, Ltd., 1979.) £7.95.

MACKAY, Colin, and COX, Tom (ed.). Response to Stress: Occupational Aspects. (A collection of papers presented at the Ergonomics Society's conference "Psychophysiological Response to Occupational Stress", University of Nottingham, September 1978.) Pp.ix + 224. ISBN-0-86103-010-9. (Guildford: IPC Science and Technology Press, 1979.) £10.

PLINER, Patricia, BLANKSTEIN, Kirk R., and SPIEGEL, Irwin M. (edited by). Perception of Emotion in Self and Others. (Advances in the Study of Communication and Affect, Vol.5.) Pp.x + 204. ISBN-0-306-40224-6. (New York and London: Plenum Press, 1979.) $24.50.

SCHNEIDER, David J., HASTORF, Albert H., and ELLSWORTH, Proeve C. Person Perception. Second edition. (Topics in Social Psychology.) Pp.xiii + 321. ISBN-0-201-06768-4. (Reading, Mass., and London: Addison-Wesley Publishing Company, 1979.) $6.

SCHUCKIT. Marc A. Drug and Alcohol Abuse: a Clinical Guide to Daignosis and Treatment. (Critical Issues in Psychiatry: An Educational Series for Residents and Clinicians.) Pp.xvii + 211. ISBN-0-306-40215-7. (new York and London: Plenum Medical Book Company, 1979.) $16.95.

SPRAGUE, James M., and EPSTEIN, Alan N. (ed.). Progress in Psychobiology and Physiological Psychology, Vol.8. Pp.xiv + 353. ISBN-0-12-542108-7. (New York and London: Academic Press, 1979.) $45.50.

THOMPSON, Travis, and DEWS, Peter B. (ed.). Advances in Behavioral Pharmacology, Vol.2. Pp.ix + 263. ISBN-0-12-004702-0. (New York and London: Academic Press, 1979.) $23.50.

WEICK, Karl E. The Social Psychology of Organizing. Second edition (Topics in Social Psychology.) Pp.ix + 294. ISBN-0-201-08591-7. (Reading. Mass., and London: Addison-Wesley Publishing Company, 1979.) $5.25.

wolfgang, Asron (edited by). Nonverbal Behavior: Applications and Cultural Implications. Pp.xxiv + 225. ISBN-0-12-761350-1. (New York and London: Academic Press, 1979.) $12.

History of science

AEPINUS'S. Essay on the Theory of Electricuty and Magnetism. Introductory Monograph and Notes by R. W. Home. transation by P. J. connor. Pp.xiv + 514. ISBN-0-691-08222-7. (Princeto, NJ.: Princeton University Press, 1979.) £23.50.

BRECHER, Kenneth, and FEIRTAG, Mochael (ed.). Astronomy of the Ancients. Pp.ix + 206. ISNB-0-262-02137-4. (Cambridge, Mass. and London: The MIT Press, 1979.) $12.50.

CCATES, V.T., and FINN, B. (ed.). A Retrospective technology Assessment: Submarine Telegraphy — The Transatlantic Cable of 1866. Pp.xv + 264. ISBN-0-911302-39-5. (San Francisco, CA.: San Francisco Press, Inc., 547 Howard Street, 1979.) $8.50.

HAXEN. Robert M. (ed.). North American Geology: Early Writings. (Benchmark Papers in Geology/51). Pp.xvii + 356. ISBN-0-87933-345-6. (Stroudsburg, Penn.: Dowden, Hutchinson and Ross, Inc., 1979. Distributed world wide by Academic Press, New York and London.) $29.50.

KUTZBACH, Gisela. The Thermal Theory of Cyclones: a History of Meteorological Thought in the Nineteenth Century. Pp.xiv + 255. ISBN-0-033876-48-3. (Boston, Mass.: American Meteorological Society, 1979.) $30.

LEAF, Murray J. Man, Min, and Science: a History of Anthropology. Pp.xiv + 376. ISBN-0-231-04618-9. (New York: Columbia University Press, 1979.) $25.

RUSE, Michael The Darwinian Revolution: Science Red in Tooth and Claw. Pp.xv + 320. ISBN-0-226-73164-2. (Chicago and London: The University of Chicago Press, 1979.) $20; £12.

WARNER, Brian. Astronomers at the Royal Observatory, Cape of Good Hope: a History with Emphasis on the Nineteenth Century. Pp.xii + 132. ISBN-0-86961-109-7. (Cape Town and Rotterdam: A.A. Balkema, 1979. Published for the University of Cape Town.) Dfl. 33.75: £7.97; $16.85.

Sociology

FREEDMAN, Daniel G. Human Sociobiology: a Holistic Approach. Pp.ix + 242. ISBN-0-02-910660-5. (New York: The Free Press, a Division of Macmillan Publishing Co., Inc.; London: Collier Macmillan Publishers, 1979.) £8.50.

MERTON, Robert K. The Sociology of Science: Theoretical and Empirical Investigations. Edited and with an Introduction by Norman W. Storer. Pp.xxxi + 605. ISBN-0-226-52091-9. (Chicago and London: The University of Chicago Press, 1973.) $8.95.

NELSON, Nici. Why Has Development Neglected Rural Women?: a Review of the South Asian Literature. (Pergamon International Library of Science, Technology, Engineering and Social Studies.) Pp.viii + 108. ISBN-0-08-023376-7. (Oxford and New York: Pergamon Press, 1979.) Hard £10; Flexi £4.

NIETZEL, Michael T. Crime and Its Modification: a Social Learning Perspective. (Pergamon International Library of Science, Technology, Engineering and Social Studies.) Pp.viii + 301. ISBN-0-08-023877-7. (Oxford and New York: Pergamon Press, 1979.) £5.

OTTOBRE, Frances M. (ed.). Criteria for Awarding School Leaving Certificated: An International Discussion. (Based on the Proceedings of the 1977 Conference of the International Association for Educational Assessment held at the Kenyatta Conference Center, Nairobi, May 23-28, 1977.) Pp.vii + 211. ISBN-0-08-024685-0. (Oxford and New York: Pergamon Press, 1979.) £11; $22.

General

ABOUCHAR, Alan. Economic Evaluation of Soviet Socialism. (Pergamon Policy Studies.) Pp.xii + 151. ISBN-0-08-023870-X. (New York and Oxford: Pergamon Press, 1979.) £7.50.

ANDREWS, Frank M. (ed.). Scientific Productivity: The Effectiveness of Research Grops in Six Countries. Pp.xxxiv + 469. ISBN-0-521-22586-0. (Cambridge, London and New York: Cambridge University Press; Paris: Unesco, 1979.) £20.

ASIMOV, Isaac, Saturn and Beyond. Pp.222. ISBN-0-688-41876-7. (New York: Lothrop, Lee and Shepard Company, a Division of William Morrow and Co., Ltd., 1979.) $7.95.

BHASKAR, Roy. The Possibility of Naturalism: A Philosophical Critique of the Contemporary Human Sciences. (Harvester Philosophy Now, Vol.8.) Pp.228. ISBN-0-85527-762-9. (Brighton: Harvester Press, Ltd., 1979.) Cloth £11.50; Paper £4.50.

BIGMORE, Peter. The Bedfordshire and Huntingdonshire Landscape. (The Making of the English Landscape.) Pp.240 + 40 plates. (London, Sydney, Auckland and Toronto: Hodder and Stoughton, 1979.) £8.95 net.

APPOINTMENTS VACANT

FACULTY POSITIONS

he Department of Zoology at the niversity of Texas at Austin is recruiting o fill two vacancies.

1) GENETICIST

hose research deals with the eucaryotic enome and its structure and/or function. his opening is at the senior level. The areas f greatest interest are: somatic cell, mole- ular and/or developmental genetics.

2) REPRODUCTIVE PHYSIOLOGIST

hose research is on the vertebrate central ervous system investigated anatomically nd/or biochemically. This individual ould be able to relate neural processes to production with an emphasis on the rmer. This position is open at the ssistant professor level, however, senior pplicants will be considered.

Applicants should submit: a curriculum tae, selected reprints, a brief statement of search plans, qualifications for graduate d undergraduate instruction, and names f 5 references.

Applications should be sent by ecember 1 1979 to the Chairman, epartment of Zoology, University of exas at Austin, Austin, Texas 78712.

The University of Texas at Austin is an qual Opportunity/Affirmative Action mployer. W609(A)

DIRECTOR, NTERNATIONAL CENTRE FOR DIARRHOEAL DISEASES RESEARCH, BANGLADESH (ICDDR, B)

he ICDDR, B is an international health search and training centre located in angladesh, and is directed toward the udy of all aspects of diarrhoeal diseases nd related aspects of fertility and utrition. It was established by an rdinance of the Government of angladesh in December, 1978. Twenty-six ations and agencies now participate in the ork of the centre. It is guided by a Board f Trustees with majority representation om developing countries. The director is esponsible for the programs and anagement of the centre.

A candidate should have a strong inter- ational reputation as a biomedical cientist and experience in managing a cientific organization. Experience in eveloping countries is desirable.

The terms and conditions of mployment are negotiable, and may be uided by policies of other international nstitutions.

Letters of application should contain a omplete curriculum vitae and should be ddressed to: Charles C.J. Carpenter, MD, hairman, Department of Medicine, Case Vestern Reserve University, Cleveland, hio 44106. W633(A)

DIRECTOR, LABORATORY FOR PLASMA AND FUSION ENERGY STUDIES

The University of Maryland at College Park invites applications and nominations for the position of Director of the Laboratory for Plasma and Fusion Energy Studies. Candidates for the position should have a distinguished reputation in research, the ability to lead in further developing the programs of a newly established laboratory and be highly qualified for appointment as a tenured Professor in a relevant department of physical science or engineering.

The prospective appointment date is on or about July 1, 1980; applications received by March 1, 1980, will receive full consideration.

Inquiries, nominations, and applications should be addressed to Dr Robert O Harger, Chairman of the Search Committee, Electrical Engineering Department, University of Maryland, College Park, Maryland, 20742. The University of Maryland is an equal opportunity, affirmative action employer. W629(A)

UNIVERSITY OF CALIFORNIA

DEPARTMENT OF UROLOGY

SCIENTIST

Full-time faculty position in Urology Department for basic scientist. We seek a person able to initiate and conduct his/her own research programs, supervise research residents and fellows, and participate in teaching of undergraduate, graduate and medical students in selected areas of immunology. Minimum criteria are PhD and/or MD degree with demonstrated competence in conducting independent research in immunology. The UC Davis campus offers unusual opportunities in basic immunologic research because of immediate proximity to the Medical School, Veterinary School and Primate Centre. A joint appointment with the appropriate Basic Science Department will be considered. Send curiculum vitae to John M. Palmer, MD, Chair, Department of Urology, UC Davis School of Medicine, 4301 X Street, Suite 249, Sacramento, CA 95817. In compliance with federal and state laws and University policy, the University of California does not discriminate on the basis of race, colour, national origin, religion, sex, handicap, age or against disabled veterans or veterans of the Vietnam era. The University is an Affirmative Action/Equal Opportunity Employer. Position open until filled. W642(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH POST

Postdoctoral applicants with experience in materials science, physics or related subjects for a 3 year research post funded by the Arthritis and Rheumatism Council to investigate mechanical properties and morphology of collageneous tissues. Previous experience in biomechanics, electron microscopy or related areas and interest in medically orientated physics or engineering is desirable. Salary in the range £4333 to £5488. (Scale under review).

Applications, including names of two referees and curriculum vitae should be sent to Dr J Shah, Department of Physics, University of Bristol, Bristol BS8 1TL by 15th February, 1980. 3974(A)

UNIVERSITY OF LONDON (BOARD OF STUDIES IN ZOOLOGY)

STEREOSCAN UNIT AT BEDFORD COLLEGE

SEM TECHNICIAN GRADE 5

required to be responsible for the operation and maintenance of the Stereoscan Microscope Unit. Duties will include preparative work associated with operation of the equipment.

Gross salary range (under review) £4480 to £5100.

Application forms from Personnel Office, Bedford College, Regent's Park, London, NW1 4NS (tel: 01-486 4400 Ext. 312). 3962(A)

Roseworthy Agricultural College

The College is situated 50km north of Adelaide, South Australia on a 1200 hectare farming property. Tertiary courses are offered in Natural Resources, Agriculture, Oenology, Wine Marketing and Farm Management.

PRINCIPAL LECTURER OR SENIOR LECTURER

NATURAL RESOURCE MANAGEMENT

DUTIES: To provide professional leadership in this field. To present a series of subjects centred on the legal, social and political background to the use of Natural Resources. The appointee will be involved in subjects such as Natural Resource Legislation, Environmental Impact Statement Methodology, Environmental Indices and Monitoring, Management Plants, Quantification of Soil, Water Vegetation and Animal Communities. A knowledge of cartographic and remote sensing techniques would be desirable.

QUALIFICATIONS AND EXPERIENCE: A degree in Science, Ag. Science or related area, with post-graduate qualifications. Involvement in research or experience in Industry or Government service at a Senior level regarded as essential.

SALARY RANGES: **Principal Lecturer up to $28,813**
Senior Lecturer I $23,924 to $25,480
Senior Lecturer II $21,861 to $23,408

APPLICATIONS: including name, address, date of birth, telephone number and qualifications, along with names and addresses of 3 referees, should be marked "Confidential" and reach the Administrative Secretary, Roseworthy Agricultural College, Roseworthy, South Australia, 5371 by January 11th 1980. W630(A)

IMPERIAL CHEMICAL INDUSTRIES LTD

UNIVERSITY OF EDINBURGH UNIVERSITY OF ABERDEEN

THE SYNTHESIS, STRUCTURE AND PROPERTIES OF NOVEL ZEOLITES

Applications are invited for the following positions financed by a Cooperative Award from the Science Research Council and ICI Ltd.

These posts offer a rare opportunity to participate in a large collaborative investigation into the synthesis and properties of an important new generation of materials which show great promise as sorbents and catalysts.

1. A Postdoctoral Research Associate to work with Drs B M Lowe and H F Leach at the University of Edinburgh on the hydrothermal synthesis and characterisation (by X-ray powder diffraction, thermal analysis and sorption) of Novel Zeolites.

2. A Postdoctoral Research Associate to work with Dr J A Gard at the University of Aberdeen on the determination of the structure of zeolites by X-ray diffraction, electron diffraction and related techniques.

3. A Postdoctoral Research Associate to work with Dr D A Whan at the University of Edinburgh on catalysis by zeolites. The principal techniques involved will be gas chromatography and mass spectrometry.

4. A Technician to work with Dr B M Lowe at the University of Edinburgh on the synthesis of novel zeolites.

5. A Technician to work with Drs H F Leach and D A Whan at the University of Edinburgh on the adsorptive and catalytic properties of zeolites.

Previous experience in the appropriate field would be advantageous but is not essential.

Appointments, which will commence between March and October 1980, will be for a period of two years with the possibility of renewal for a further period.

Initial salaries for Postdoctoral Research Associates will be in the range £4,622 to £5,488 (under review) on scale 1A for Research and Analogous Staff.

Initial salaries for Technicians will be in the range £3,699 to £4,065 (under review) on scale TG5. Further information about specific positions may be obtained directly from the academic staff members indicated.

Applications (3 copies), including curriculum vitae and the names and addresses of two referees should be sent as soon as possible and not later than 1st Jan. to

Dr N H Ray,
The Corporate Laboratory,
Imperial Chemical Industries Ltd,
P.O. Box No. 11,
The Heath, Runcorn, Cheshire WA7 4QE 3992(A)

STAFF FOR THE BASIC SCIENCES UNIVERSITY OF IOANNINA MEDICAL SCHOOL

The University of Ioannina Medical School has openings for positions of EPIMELITAI starting March 1980 or later in the following Laboratories: 1) Biological Chemistry; 2) Biology; 3) Medical Physics; 4) Microbiology; 5) Pharmacology; 6) Physiology.

Candidates should be fluent in Greek, have a PhD in the above or related fields, or an MD with strong interests and experience in the above subjects.

The successful candidates will be expected to take part in the teaching programme for about 100 medical students and participate in research in the above areas. The basic salary is about 20,000Drs per month before taxes and is expected to be supplemented from other sources.

Applicants should forward their curriculum vitae with bibliography, two or more letters of recommendation, and a brief outline of research interests to: Orestes Tsolas, PhD Professor, Laboratory of Biological Chemistry, University of Ioannina Medical School, Ioannina Greece (Telephone 0651 33442). W634(A)

UNIVERSITY OF QUEENSLAND

LECTURER IN PHYSIOLOGY

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

The appointee will be expected to pursue an active research programme. Present areas of research activity include female reproduction, endocrinology, fetal and cardiovascular — renal physiology and andrology. 29.2.80.

SENIOR TUTOR IN BIOCHEMISTRY

Minimum qualification is a PhD in Biochemistry. The appointee will be required to undertake teaching and research in Biochemistry. 4.1.80.

SENIOR TUTOR IN ZOOLOGY

Applicants should have a higher degree or Honours and experience in Vertebrate Zoology. Ability to organise practical classes essential. 7.1.80.

Salaries: Lecturer: $A16,291 to $A21,401 p.a. Senior Tutor: $A14,041 to $A16,085 p.a.

Other benefits: Lecturer: Opportunities to undertake programme of special studies, superannuation, housing assistance, travelling and removal expenses. Snr. Tutor: Superannuation, housing assistance, travelling and removal expenses.

Additional information and application forms are obtainable from the Association of Commonwealth Universities, (Appts) 36 Gordon Square, London WC1H 0PF.

ARGC RESEARCH ASSISTANT GRADE 1 PHYSIOLOGY & PHARMACOLOGY

A post-doctoral graduate with biochemical experience required for reproductive endocrinology on the role of granules and binding proteins in the secretion of steroid hormones. Experience in one of the following areas would be an advantage: steroid biochemistry, protein purification, sub-cellular fractionation. Enquiries: Professor G.D. Thorburn, University of Queensland, St. Lucia, Queensland 4067, Australia. Quote Ref No 44979. 3987(A)

UNIVERSITY OF MARBURG

DEPARTMENT OF ANATOMY AND CELL BIOLOGY

RESEARCH AND TEACHING ASSISTANT

Applications are invited for a postgraduate research and teaching assistant, who is required to work on developmental aspects of the autonomic nervous system.

Experience in neurobiology, particularly in neurochemistry, cell culture or electron microscopy would be an advantage.

Salary according to BAT IIa (DM3,000 to DM3,200 per month).

The appointment may be taken up immediately.

Applications (two copies) giving details of age, education, language abilities and experience together with the names and addresses of two referees should be sent to Professor K. Unsicker, Department of Anatomy and Cell Biology, Philipps-University, D-3550 Marburg, West Germany. W638(A)

FACULTY POSITION

DEPARTMENT OF BIOLOGICAL CHEMISTRY

UNIVERSITY OF CALIFORNIA

Davis

School of Medicine

Applications are invited for a faculty position at the rank of assistant or associate professor, to begin Spring or Summer 1980.

Candidate should be active in research capable of contributing significantly to Medical School and Graduate teaching in the areas of biochemistry, physiological chemistry, cellular and molecular biology.

Quality and originality of research will receive greater emphasis than field of specialization although potential to enter into interdisciplinary research within the Department, encompassing the areas mentioned above will be given favorable consideration.

Applicants should send a curriculum vitae, list of publications, future research plans and the names of at least three individuals from whom letters of recommendation may be solicited by the Search Committee to: Dr. Robert R. Traut Chairperson, Search Committee Department of Biological Chemistry School of Medicine, University of California, Davis, CA 95616.

Completed applications should be received not later than January 31, 1980. The University of California is an affirmative action/equal opportunity employer. Women and minority candidates are encouraged to apply. W636(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GEOGRAPHY

Applications are invited for the post of

RESEARCH ASSISTANT

to assist Dr A Henderson-Sellers in NERC funded theoretical investigation of the methods of parameterising albedo using satellite data. Candidates should have a good science degree including considerable experience in computing techniques. Some knowledge of atmospheric physics would be useful.

The post is tenable for one year at a salary of £3,775 per annum.

Applications, together with the names of three referees, should be received not later than 18th January, 1980 by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/873. 3984(A)

GUY'S HOSPITAL

MEDICAL SCHOOL

POSTDOCTORAL RESEARCH ASSISTANT

required to work with Dr L Mallucci in the Department of Microbiology on a project supported by the Cancer Research Campaign on "The Role of Surface Components in Control of Cell Growth".

Research will involve isolation and characterisation of components that affect events related to cell division.

The appointment is available for three years and the initial salary will be within the range £4,033 to £6,066 (under revision) plus £740 London Allowance.

Apply in writing with full curriculum vitae and the names of two referees to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C. 3993(A)

Entomologist/ Insecticides Research

Shell Biosciences Laboratory has a vacancy for a graduate entomologist to work in the Biological Evaluation Division of their Sittingbourne Research Centre in Kent. The person appointed will become a member of an innovative and lively team involved in the search for new insecticides. A basic knowledge of and interest in entomology including insect rearing techniques is considered essential, together with sufficient knowledge of organic chemistry to appreciate the structure/activity relationship. The post is seen as an important and challenging one at a time when the future course of insect pest control is being widely reviewed. The job will be laboratory based primarily although opportunities for field work will arise.

Sittingbourne Research Centre is a large, modern, well-equipped site with outstanding Laboratory, sports and social facilities and an excellent subsidised staff restaurant. We offer a competitive salary and good career prospects.

Applicants should be below 30 years of age, have at least an upper second class honours degree, and post-graduate experience in entomology preferably leading to a PhD.

Please write or telephone for an application form to:

Shell Research Limited, The Recruitment Division, (N1) PNEL/11, Shell Centre, London. Telephone 01-934 2948.

3972(A)

THE UNIVERSITY OF HULL

LECTURER IN GEOPHYSICS

pplications are invited for the post of ecturer in Geophysics in the Department f Geology, tenable from 1 October, 1980. he person appointed will be responsible or teaching courses in geophysics, xploration geophysics and geological map ork. Preference may be given to ndidates with research interests in the ophysics of mineral exploration.

Salary will be on the scale £4333 to £8992 er annum (under review) with initial acing in the range £4333 to £5199 per nnum.

Applications (six copies) should give full articulars of age, qualifications and xperience, together with the names of ree persons from whom references can be ought, and be lodged not later than 1 larch 1980, with The Registrar, University f Hull, HU6 7RX, from whom further articulars can be obtained. 3975(A)

UNIVERSITY OF ST. ANDREWS

DEPARTMENT OF PSYCHOLOGY

Applications are invited for the post of RESEARCH ASSISTANT in the Department of Psychology, primarily to work on a three-year S.R.C. sponsored project on The Role of the Superior Colliculus in Pattern Perception in Rats.

Applications should preferably have a degree in Psychology, but graduates in related disciplines who have a strong interest in physiological psychology will be considered.

Starting salary £3,775 per annum on Research scale 1B, plus U.S.S.

Applications (two copies preferably in typescript) with the names of three referees should be lodged by *31st January 1980* with the Establishments Officer, The University, College Gate, St. Andrews, Fife, from whom further particulars may be obtained. 3990(A)

RUHR-UNIVERSITÄT BOCHUM

An der **Abteilung für Biologie** ist die Stelle eines

Ordentlichen Professors (H4) für Pflanzenphysiologie

wieder zu besetzen. Es handelt sich um die Nachfolge M.H. Zenk. Personal- und Sachmittel sind vorhanden. Lehrverpflichtungen für das Fach Pflanzenphysiologie entsprechend der Studienpläne.

Bewerbungen mit Lebenslauf und Schriftenverzeichnis sind bis zum **31.3.1980** and den **Dekan der Abteilung für Biologie, Postfach 10 21 48, 4630 Bochum 1,** zu richten. W628(A)

CHANGE OF ADDRESS

The Advertisement offices for NATURE have moved to

4 LITTLE ESSEX STREET, LONDON WC2R 3LF

TELEPHONE: 01 240 1101

Positions in
ELECTRON MICROSCOPY
Boston, Massachusetts

Tufts University, School of Medicine, an academic institution actively involved in research, has two positions available in the field of Electron Microscopy. We are seeking skilled, enthusiastic applicants who have a commitment to continued self development. Both of these jobs entail working closely with several investigators and our needs are best filled by a congenial, highly motivated person.

MOLECULAR BIOLOGY

Individual will have prime responsibility for youth, operational maintenance and supervision of a multi-user EM complex which includes a JOEL 100S and 100B. This person will serve as a resource, helping investigators choose, develop, learn and apply EM techniques to their particular research problems. Applicants must have some experience in negative staining, evaporation, and appropriate darkroom techniques. Many of the applications involve spreading and visualizing molecular structures such as DNA heteroduplexes, nucleic acid-protein complexes and phage substructure.

ANATOMY

This department requires the cultivated skills of a person to supervise a common access facility for transmission electron microscopy. Candidates should demonstrate experience in: (1) tissue preparation, embedding, sectioning and contrast staining of epoxy embedded tissue. (2) Operator maintenance of EM including filamenting and stigmation of electron microscopes (Phillips AM200, Joelco 100B, RCA EMU-3H) and (3) general photography, particularly darkroom work. The individual will be expected both to help department personnel learn instrument use and procedures and also to perform technical work for some of the faculty involved.

To apply for either of the above positions, please submit résumé, specifying which one interests you. Please include your salary history and requirements and send to: Tufts University, Personnel Office, Attention: Ina-Lee Block, 63 Kneeland Street, Boston, MA 02111 USA.

An Equal Opportunity/Affirmative Action Employer

TUFTS university

HOUGHTON POULTRY RESEARCH STATION

TEMPORARY SENIOR SCIENTIFIC OFFICER AND HIGHER SCIENTIFIC OFFICER IN THE PARASITOLOGY DEPARTMENT

Vacancies exist for a Senior Scientific Officer and a Higher Scientific Officer in a team investigating the production of attenuated strains of the species of *Eimeria* causing coccidiosis in domestic poultry, and their utilisation for immunisation of young chickens. The appointments are temporary for three years funded by the National Research Development Corporation as part of a programme of research to develop an effective vaccine against coccidiosis.

SENIOR SCIENTIFIC OFFICER

Applicants should have at least four years post-graduate research or other approved experience, and should hold a PhD degree with post-doctoral experience in protozoan biology, cell culture or biochemistry.

HIGHER SCIENTIFIC OFFICER

The post is of a technical nature and applicants should have a degree, HNC or equivalent in a science subject, with at least 5 years relevant post qualifying experience, with appropriate practical experience in microbiology. Experience in protozoology is not necessary.

Appointment in the Senior Scientific Officer grade will be on a salary within the scale effective from 1st January 1980, £6,332 to £6,957, and the appointment in the Higher Scientific Officer grade will be on a salary within the scale effective from 1st January 1980, £5,097 to £6,030. Non-contributory superannuation scheme.

Further particulars and application form from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs. PE17 2DA. Closing date for applications 25th January, 1980. 3973(A)

ROYAL UNITED HOSPITAL, BATH

RESEARCH BIOCHEMIST

Required to take part in a 3 year study of platelet and lipid metabolism in diabetic subjects. Post based in the Laboratories of the Clinical Investigation Dept and facilities also available in the Dept of Biochemistry at Bath University. Salary at the appropriate point on the scale for Hospital Biochemists.

Enquiries to Dr. J.P.D. Reckless on Bath 28331 Ext 735.

Application forms from Sector Administrator, Royal United Hospital, Bath. Tel: Bath 28331 Ext 606. 3971(A)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF ZOOLOGY

POSTGRADUATE RESEARCH ASSISTANT

Applications are invited from graduates with interests in Cell Biology and Neurobiology to work on a project investigating the appearance and distribution of glutamate receptors on locust muscle. Techniques involved will include electron microscopy and freeze-etching and some practical experience in neurobiology or electron microscopy would be an advantage.

The project is funded by SRC for three years and the appointment will be made as soon as possible at a starting salary of £3,775. Applicants may register for a higher degree if they wish to.

Letters of application including the names of two referees to Dr I R Duce, Department of Zoology, University of Nottingham, University Park, Nottingham NG7 2RD. 3986(A)

THE ROYAL VETERINARY COLLEGE
University of London

DIVISION OF PARACLINICAL STUDIES

DEPARTMENT OF PATHOLOGY

LECTURER IN VETERINARY PATHOLOGY

Applications are invited from veterinary graduates for the post of Lecturer in Veterinary Pathology. Duties will include diagnostic work and participation in teaching the undergraduate and postgraduate courses in pathology. The successful applicant will be encouraged to take advantage of the good research opportunities which are available.

Preference will be given to applicants having some relevant experience in post-mortem diagnosis, histopathology or similar fields, but consideration will be given to applications from recent graduates or others.

Salary scale (under review): £5073 to £9732 inclusive of London Allowance. Initial salary will be determined according to qualifications and experience. Superannuation under the Universities' scheme.

Removal expenses up to £800 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone: 01-387 2898.

Closing date for applications: 14 January 1980. 3963(A)

UNIVERSITY OF SOUTHAMPTON

CRC MEDICAL ONCOLOGY UNI

Applications are invited for t position of

POST-DOCTORAL RESEARCH ASSISTANT

to work on the isolation and purificatio membrane proteins and glycoprot involved in cell adhesion of *Dictyostel discoideum*. Candidates should have, o about to obtain, a PhD in Biochemis Some experience of working with m branes, proteins or carbohydrates woul advantageous. The appointment whic funded by the Science Research Cou will be for 3 years and the success applicant will be expected to take up hi her duties as soon as conveniently possi Salary on scale 1A £4,333 to £5,488 pa.

Applications, giving the names of t referees, should be sent to Dr D.R. Garr CRC Medical Oncology Unit, Cen Block, Southampton General Hospi Southampton SO9 4XY.

Please quote Ref: N. 3985(A

UNIVERSITY COLLEGE DUBLIN

POST IN MASS SPECTROMETRY

Applications are invited from suita qualified persons for a full-ti appointment in mass spectrometry. T post will involve the operation of a 70-70H Mass Spectrometer and Incos 2 Data System, providing a service teaching and postgraduate work within University. Candidates, preferal possessing an Honours degree equivalent qualification in Chemist Biochemistry, should have experience mass spectrometry and/or gas chron tography.

Salary £4,268 to £6,128 per annu Entry point may be above the minimum

Applications, together with the names two referees, should be forwarded to: T Secretary, Department of Agricultu Chemistry & Soil Science, Agricult Building, UCD, Belfield, Dublin 4.

The closing date for receipt applications is Friday, 28th Decemb 1979. 3964(A)

THAMES POLYTECHNIC

SCHOOL OF BIOLOGICAL SCIENCES

RESEARCH ASSISTANT IN PLANT BIOCHEMISTRY/ CELL BIOLOGY

Applications are invited from go honours graduates in biochemistry or related discipline to investigate changes the metabolism of polyamines and relat amino acids during the transition embryogenesis in cultured carrot cells, part of an on-going study into biochemic aspects of this transition. The work will jointly supervised by Dr A.W. Davids and Dr R.J. Yon. The successful applica will be expected to register for a high degree of the CNAA.

Salary scale: £3321 to £3705 inclusive.

Further particulars and form application may be obtained from t Staffing Officer, Thames Polytechn Wellington Street, London, SE18 6PF, whom completed applications should returned by 8th January 1980. 3969(A)

Opportunities in Biological Development

G. D. Searle, whose modern, well-equipped research laboratories are located in pleasant surroundings at High Wycombe in Buckinghamshire, is currently engaged on exciting work in the field of Biological Development, and has created the following new positions:

Cell Biologist (Ref. CB/R15)

We require a PhD in animal cell physiology or related discipline to lead a small team in the development of scale up tissue culture systems, cell growth monitoring, and in the development of control systems for process optimisation.

The ideal candidate will have experience in animal cell culture, especially large scale culture, and may have experience in the manipulation of the synthesis of cellular synthetic processes.

Protein Chemist (Ref. PC/R15)

We require a PhD in protein chemistry or related field to provide new impetus and direction in this area and to play a central role in the protein purification group.

Applicants should have experience in protein isolation techniques and in analysis of complex protein mixtures. They must possess understanding of modern techniques to resolve interacting protein species, and knowledge of the factors contributing to protein stability in such systems.

Bioengineer (Ref. B/R15)

We require a Bioengineer to become involved in plant design, construction, operation and maintenance, and to develop process control systems.

Applicants should have a qualification of HND or degree standard and should have at least two years' experience in industry. A sound practical and theoretical knowledge of fermentation plant and equipment is essential. Experience with mammalian cell culture would be an advantage, and a working knowledge of electronics as applied to fermentations would be useful.

All these positions offer attractive salaries, and benefits include 4 weeks' holiday per year, contributory pension and private health insurance schemes, subsidized cafeteria, and sports and social club.

Please apply in the first instance to Miss D. Wardman, Assistant Personnel Officer, Searle Research & Development, Lane End Road, High Wycombe, Bucks. (Tel. High Wycombe 21124, ext. 3374).

ICI

CHEMIST/PHYSICIST
TO LEAD RESEARCH ON NMR TECHNIQUES

The ICI Corporate Laboratory, situated in Runcorn, Cheshire, is looking for an enterprising and imaginative PhD scientist (with or without post-doctoral experience) to take a leading role in developing the Company's use of advanced nuclear magnetic resonance techniques. He/she must have first class research experience in developing and/or applying NMR techniques in chemistry or biochemistry, and be keen to develop and exploit novel NMR applications in the chemical industry.

The Company's wide-ranging research interests will offer the successful applicant scope for working in a variety of areas, which may include organic and inorganic chemistry, catalysis, colloid science, materials science, biochemistry and biology. The direction of the work will depend to a large extent on his/her experience and research interests. An interest in novel biological applications would be an advantage, but applicants with other interests relevant to the industry's long-term technological needs will be considered.

In adddition to an attractive salary, there is a profit-sharing scheme and assistance with removal expenses.

If you are interested in this vacancy, please reply enclosing a full curriculum vitae to:—

Miss S E Bird, Personnel Officer
IMPERIAL CHEMICAL INDUSTRIES LIMITED
Corporate Laboratory
PO Box 11, The Heath, RUNCORN, Cheshire WA7 4QE

3967(A)

Physiologist/ Biochemist

We are seeking a Physiologist/Biochemist within our Toiletries Division to explore the biochemical and physiological situation of the mouth. The post which will be at Scientist level may, therefore, be expected to involve both laboratory benchwork and studies on human subjects. A wide knowledge of biochemical techniques will be necessary, so the successful candidate will probably possess relevant postgraduate experience, but equally important will be a pleasant personality with an ability to communicate on an abstract level. An interest in human psychology is essential.

The Company operates a progressive salary and promotion policy, good superannuation and life cover benefits are provided and, where appropriate, will assist with removal expenses.

The Laboratory is situated on the Wirral Peninsula, a few miles from the sea and convenient for Chester, Liverpool and North Wales.

Applications are invited from both males and females, who should write for an application form, quoting reference no. 665 M to

Personnel Officer, Unilever Research Port Sunlight Laboratory, Port Sunlight, Wirral, Merseyside, L62 4XN.
Closing date: 31 December, 1979. 3982(A)

unilever research

THE UNIVERSITY OF LANCASTER
DEPARTMENT OF ENVIRONMENTAL SCIENCES
RESEARCH ASSISTANT

Applications are invited for a Research Assistantship to work with Dr J Hamilton-Taylor and members of the Freshwater Biological Association on the investigation of heavy metal cycling in Windermere, Cumbria.

Applicants should be graduates in chemistry, geology or a biological/environmental science and have post-graduate/doctoral experience in environmental chemistry. The appointment, funded by NERC, will be for a period of three years and will commence as soon as possible. The starting salary will be in the range £3775 to £4333 depending on qualifications.

Further particulars may be obtained (quoting reference L173) from the Establishment Officer, University House, Bailrigg, Lancaster, LA1 4YW, to whom applications (five copies), naming three referees, should be sent by 14 January, 1980. 3968(A)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF BACTERIOLOGY
LECTURER

Applications are invited for the post of Lecturer with teaching and research duties in laboratory aspects of infectious disease. Candidates should have a medical or higher science qualification, with experience in medical laboratory microbiology and undergraduate teaching and preferably with an interest in clinical bacteriological research and development.

The clinical salary scale for medically qualified lecturers is £5,316 to £9,420. The non-clinical scale for science graduates is £4,333 to £8,992. USS Superannuation.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL, with whom applications (8 copies) including curriculum vitae and the names and addresses of two referees should be lodged not later than 20th January, 1980. ANNOUNCEMENTS

A NATO Advanced Study Institute on Chemically Sensitive Electronic Devices will be held at the Peddie School, Hightstown, NJ from 9 June to 21 June 1980. The fundamental principles of transducer action for chemical sensors, the resulting device physics and selected areas of application will be presented in a series of lectures by: P Bergveld and G A Bootsma, Twente Technical University; R Buck, University of North Carolina; G Farrington, General Electric; M Green, Imperial College; T. Matsuo of Tohoku University; I Lundström of Linköping University; I Lauks and J N Zemel, University of Pennsylvania; S Pace, Stauffer Chemical.

This course is primarily intended for the young researcher at the post doctoral level but consideration will be given to anyone in the process of initiating research in these areas. The student body will be sought from a broad range of disciplines such as: electrical engineering, chemistry and chemical engineering, physics, material science and biomedical science and engineering. Limited travel and living assistance is available. Special arrangements are being made to provide low cost travel to and from the Peddie School.

For further information and applications write to either:

J N Zemel
University of Pennsylvania,
Moore School/D2,
200 S. 33rd Street,
Philadelphia, Pa. 19104. USA.

P Bergveld

ASSISTANTSHIPS

UNIVERSITY COLLEGE CARDIFF

Applications are invited for two

POST-DOCTORAL RESEARCH ASSISTANTSHIPS in the

DEPARTMENT OF BIOCHEMISTRY

(a) The study and isolation of enzymes responsible for alcohol and wax-ester synthesis in bacteria, and their role in the regulation of membrane function (with Dr. N J Russell). The project will involve the purification and characterisation of membranes and individual enzymes, radio-chemical enzyme assays and the setting-up of capillary-g.l.c. equipment.

(b) A study of the distribution and metabolism of chloroplast thylakoid lipids (with Dr J L Harwood). This project will involve the isolation and characterisation of sub-cellular particles, examination of lipid sidedness by chemical and enzymatic techniques and a study of the turnover of individual components *in vivo*.

Both positions are funded by the S.R.C. for three years. Initial appointment will be at the 1st-3rd points of the 1A scale (£4333 to £4910, under review) according to age and experience.

Applications (2 copies) including a curriculum vitae together with the names and addresses of two referees and indicating the post of interest, should be sent to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL. Closing date 31st January 1980. Reference 1946. 3980(P)

WORKSHOP

TEPHRA STUDIES AS A TOOL IN QUATERNARY RESEARCH

A NATO Advanced Studies Institute on this subject will be held in Iceland from June 18th to 30th 1980. The ASI will consider all applications of tephra (volcanic ash) studies to Quaternary geological problems: dating, correlation, stratigraphy on land and in the ocean, history of active volcanoes, eruption prediction and styles of volcanism. The ASI will include 5 days of field excursions in Southern Iceland examining pyroclastic deposits. Participants from NATO countries are eligible for partial financial support. Interested persons should apply for further information to:—

Dr R S J Sparks, Department of Mineralogy and Petrology, University of Cambridge, Cambridge CB2 3EW, England. 3981(V)

SCHOLARSHIPS

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICS

Applications are invited from United Kingdom citizens holding a good Honours degree in physics, chemistry, mechanical engineering or similar discipline for a

RESEARCH SCHOLARSHIP

tenable for three years from February 1980 for a PhD project on mechanical memory metals.

The scholarship is funded by the British Gas Corporation at a rate somewhat greater than the normal SRC research studentship.

Applicants should write as soon as possible, naming two referees, to Dr K H G Ashbee, H H Wills Physics Laboratory, Tyndall Avenue, Bristol BS8 1TL.

3989(H)

COURSES

Under the sponsorship of the European Communities, the Department of Molecular Biology and Plant Physiology, University of Aarhus, Denmark, is organizing an interdisciplinary laboratory course to take place in Aarhus, from 17 to 30 August 1980 on

Organization and function of Specific Eukaryotic Genes

Organizers: Ole Westergaard, Johan C. Leer and Ole F. Nielsen

Participants in the course will perform a variety of fundamental experiments on the molecular biology of eukaryotic genes with emphasis on chromatin: Mapping of coding and intervening sequences on specific genes; chromatin structure of active and inactive genes; transcription of specific genes; replication and repair on the level of chromatin. Seminars and discussions will complete the practical work.

The teaching staff will include:

Christine Brack, Basel
Richard Braun, Bern
Sergey Borchsenius, Leningrad
Gunna Christiansen, Aarhus
James E. Cleaver, San Francisco
Bertil Daneholt, Stockholm
Sarah Elgin, Cambridge, USA
Jan Engberg, Copenhagen
Richard Flavell, London
Hans Klenow, Copenhagen
Ron Laskey, Cambridge
Alan R. Lehman, Brighton
Pierre Oudet, Strasbourg
Lennart Philipsson, Uppsala
Rudi Planta, Amsterdam
Robert Roeder, St. Louis
Michael Trendelenburg, Heidelberg

Staff of Department of Molecular Biology and Plant Physiology, University of Aarhus.

The number of participants will be limited.

The working language of the course will be English.

Applications for enrolment should be sent before 20 March 1980 to the Molecular Biology and Radiobiology Course Secretariat, Commission of the European Communities, DG XII, 200 rue de la Loi, B-1049 Brussels and should contain the following items: (1) name, address and academic affiliation; (2) age and nationality; (3) scientific curriculum; (4) statement on knowledge of languages; (5) list of publications, if any; (6) motivation for the application; (7) a letter from the applicants head of laboratory; (8) any other information that may be useful to the selection committee in evaluating the application. Further information may be obtained from the same address. W631(D)

MOLECULAR AND CELLULAR ASPECTS OF EARLY MAMMALIAN DEVELOPMENT ADVANCED STUDY COURSE: CRETE, SEPTEMBER 21st-28th 1980

Applications are invited from suitably qualified research workers for attendance at this lecture and discussion group course on modern approaches to the study of early mammalian development co-sponsored by The European Molecular Biology Organization and The Rockefeller Foundation. The Organizing Committee of W.D. Billington (Bristol), M.I. Sherman (New Jersey), A. Psychoyos (Paris), A. McLaren (London) and J. Danezis (Athens) will be assisted in the teaching by a panel of distinguished international experts in this field. Instruction will be entirely in English. The course will be held on the island of Crete immediately following the International Embryological Conference in Athens and its location in a small Academy will allow teachers and participants to be accommodated together in an informal atmosphere conducive to the fullest exchange of information and ideas in this important and rapidly expanding subject.

There will be a registration fee of US$60 but accommodation, meals and transport from Athens — Crete will be provided free of charge. Some bursaries to help towards travel expenses may also be available for applicants with limited financial resources. Attendance will be limited to 80-100 participants, mainly in the early post-doctoral stages of their career, and early application is advised. **Further details and forms of application are available from Dr. W.D. Billington, Department of Pathology, University of Bristol, The Medical School, University Walk, Bristol BS8 1TD, UK, to whom completed applications must be returned not later than March 31st 1980.** 3977(D)

FELLOWSHIPS

UNIVERSITY OF OXFORD
BRASENOSE COLLEGE
PLATNAUER JUNIOR RESEARCH FELLOWSHIP

The College proposes to elect a Platnauer Junior Research Fellow (male or female) in the Natural Sciences or Mathematics.

The tenure will be for three years from 1 October 1980 with the possibility of renewal for a further three years. The stipend of a Junior Research Fellow is at present £3,200 per annum and is subject to periodical review. Other benefits include free accommodation, or an allowance in lieu, and a grant for approved research expenses, which may include travel.

There will be no examination. Election will be made after interview.

Candidates must, within the seven years ending 1 October 1980, have either qualified for the degree of BA at Oxford or obtained an equivalent qualification elsewhere.

Applications accompanied by a curriculum vitae and the names of three referees should reach the Principal of Brasenose College, from whom further information may be obtained, not later than 18 January 1980. 3978(E)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF PATHOLOGY
RESEARCH FELLOWSHIP

Applications are invited for a post-doctoral Research Fellowship in a group studying the factors responsible for DNA stability and degradation within mammalian cells throughout the cell cycle and during programmed cell death. Experience with mammalian or viral chromatin is desirable but candidates with a relevant cell biological background will be viewed favourably. The post is available now and is supported by the Cancer Research Campaign on the nationally agreed 1A Salary Scale for 3 years in the first instance with a possibility of further renewal.

Applications enclosing a Curriculum Vitae and the names of two referees should be sent to Dr A H Wyllie, Department of Pathology, University of Edinburgh Medical School, Teviot Place, Edinburgh, EH8 9AG, by 25th January, 1980. Please quote Reference 5074 3991(E)

INTERNATIONAL INTERNSHIPS AND RESEARCH FELLOWSHIPS at the INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS

A limited number of research Internships and Fellowships are available within multi-disciplinary research programs for the rainfed semi-arid tropics. Potential research areas: plant breeding, genetics, physiology, pathology, entomology, biochemistry, microbiology, agroclimatology, agronomy, cropping systems, soil science, land and water management, agricultural engineering.

Requirements: Recent PhD or MSc, research interest within ICRISAT mandates. Competitive compensation, furnished apartment or dormitory, economy class air fares. Apply to Director, ICRISAT, Patancheru PO, AP 502 324, India. W635(E)

NEW YEAR CLOSING DATES

In view of the New Year holiday Nature Classified will close as follows:—

Jan 3 issue closing
1 pm 27.12.79.

Typesetting: J.W. Arrowsmith Ltd, Bristol and Outline Graphics Ltd. London EC4. Printing: Web Offset by The Chesham Press Ltd, Chesham, Bucks, in association with Godfrey Lang Ltd, London EC4A 1EB and The William Byrd Press Inc., Richmond, Virginia. Published by MACMILLAN JOURNALS LTD, 4 Little Essex Street, London WC2R 3LF. — 20-27 December 1979.

Monoclonal Anti-Thy 1.1 Anti-Thy 1.2

Extraordinarily specific and sensitive.
Superior to conventionally produced antisera.

Monoclonal Anti-Thy 1.1
In 0.25ml ascites fluid
Titer: 10^{-5} NEI-002

Monoclonal Anti-Thy 1.2
In 1ml ascites fluid
Titer: 10^{-6} NEI-001

In 1ml buffered ascites fluid
Titer: 10^{-5} NEI-001A

Not for use in humans or clinical diagnosis.

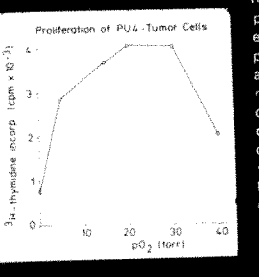
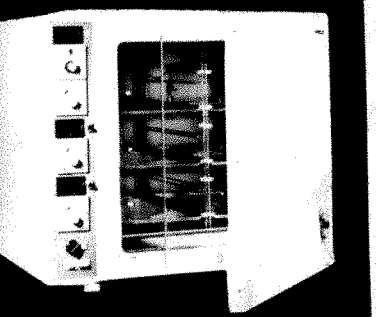
A new approach in tissue culture



PETRIPERM
a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents



PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 75 μm thick membrane.

Heraeus— Co_2-Incubator B 5060 EK/CO_2

We build the incubator with appropriate pCO_2, pH and pO_2 control units

THE LEITZ DIALUX 20 – TODAY'S MICROSCOPE FOR TOMORROW'S DEVELOPMENTS

The LEITZ DIALUX 20 has been designed with an eye to the future development of microscopy: the established Leitz modular principle has been extended as a result of current experience: it is now even more practical, and offers optimum operating convenience with maximum functional reliability.

A considerably improved arrangement of the optical illuminating system makes the LEITZ DIALUX 20 even more efficient for all optical examinations of transparent specimens. It has been possible to enlarge the microscope field of view even further through the use of the excellently corrected series of LEITZ NPL FLUOTAR objectives. Amounting to more than 23% when compared with that of conventional microscopes – with critical definition across the entire image, this ensures that the new LEITZ DIALUX 20 is not only a reliable tool for diagnostic microscopy, but also a basic instrument that has the necessary reserves for biological research. We should like to convince you of the extremely favourable relationship between performance and price.

☐ I should like to know mor about the LEITZ DIALUX 20 an would be pleased to receive fu details.
☐ I should like to arrange a date for the Leitz consultant to visit m
